Indian Journal of Public Health Research & Development

Print-ISSN: 0976-0245-Electronic-ISSN: 0976-5506, Frequency: Quarterly (Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare. The journal is now part of DST, CSIR, and UGC consortia.

Abstract

Background: Oral lichen planus (OLP) is considered as a chronic inflammatory mucocutaneous disorder. It has also been classified as a potentially malignant component in the oral counterpart lesion (OLP). The treatment of choice involves topical or systemic corticosteroids, but other drugs may also be used. Heat shock proteins (HSPs) are dynamized by both Environmental and patho-physiologic stresses thus enabling the cells to survive from stressful conditions. Heat shock proteins show an increased expression in a range of human cancers. Yet the role of HSP' s in carcinogenesis is ambiguous. The aim of this paper helps us identify the Heat shock protein 90 as a potential and promising target in the treatment and management.

Methodology: Real time PCR was performed for 90 samples. The RNA was extracted using TRIZOL. cDNA was reverse-transcribed. HSP90 primers and beta actin primers. HSP90 and beta-actin in parallel with were amplified in triplicate.

Results: Showed increase in expression from normal when compared to study groups. This was measured by fold changes. As the disease progressed, levels of HSP 90 gene expression also increased accordingly and was found statistically significant ($p<0.0001$) amongst the study groups.

Conclusion: The role of HSP 90 has been identified by genomic analysis. This forms a clear foundation for further research to develop targeted therapy for lichen planus targeting HSP 90 gene.

Keywords: *Oral lichen planus, Heat shock protein 90, targeted therapy.*

Introduction

Oral lichen planus (OLP) is considered as a chronic inflammatory disease and a potentially malignant disorder with a malignant transformation rate of 0.5-2%[1]. The commonly involved sites are buccal mucosa, gingiva and tongue. It clinically presents as bilateral white striations or papules on the involved sites. Erosions and blistering along with erythema may be seen. Almost 50% of patients who have oral lichen planus also have skin lesions. Skin lesions in LP usually resolve within 1-2 years where as in OLP they persists as long as 20 years or more. OLP affects approximately 1-2% of the general adult population, all races can be affected and the female to male ratio is 1.4:1.3,[10]. As of date, there is no curative therapy. Topical corticosteroids promote healing of erosive areas, but do not eliminate lichen

planus. Systemic steroid therapy is used to reduce the submucosal lymphatic infiltrate and inflammatory signs but at the same time adverse and long-term side effects associated with steroids such as candida overgrowth or even adrenocortical suppression restricts its usage to minimum.[9]

Heat shock proteins 90 and Oral Lichen planus: Heat Shock protein 90 (HSP 90) is an essential ubiquitous protein. It is been expressed throughout the eukaryotic lineage. High stress and anxiety levels have been strongly correlated as the etiological cause of OLP. Although this association has been known for decades, difficulties in objectively measuring these variables has been a limitation. Recently the importance of anxiety and stress been widely recognized; these factors are now the target of numerous studies. Soto-Araya et al. (2004) investigated the relation between psychological stress and disease of the oral mucosa which proved to be statistically significant[12]. Molecular Studies eliciting the exact role of HSP 90 in the pathogenesis of the disease and as a target for treatment for Oral lichen planus are very limited.

Pathogenesis of Oral Lichen Planus: OLP is a autoimmune disorder mediated by CD8+ T cells. They lead to auto-cytotoxic apoptosis of the basal cells of the oral squamous epithelium. [4] The basal keratinocytes thereby express or unmask an antigen which may be a self peptide or a heat shock protein. [5]. Subsequently, the T cells (for the most part CD8+ and some CD4+ cells) enter the squamous epithelium of the mucous membrane. This happens either due to routine surveillance to encounter an auto antigen or due to a chemokine mediated migration towards the basal keratinocyte.[5] Activation of T cells takes place when the antigen (on the basal keratinocytes) binds to major histocompatabitily complex-1 (MHC-1) or through CD4+ helper cells. In addition, as the MHC-II expression gets upregulated, the Langerhan cells in OLP also show a increase in the number. This increase is followed by antigen presentation to CD4+ cells. Interleukin -12 activates CD4 + T helper cells which activate CD8+ T cells through receptor interaction, interferon γ (INF – γ) and IL-2. The activated CD8+ T cells in turn kill the basal keratinocytes through tumor necrosis factor (TNF)-α, Fas– FasL mediated or granzyme B activated apoptosis.[8]

Treatment regimen currently followed for Oral Lichen Planus: Topical steroids have been found to be effective in treating symptomatic oral lichen planus by reducing pain and inflammation. But controversially the over usage of systemic corticosteroids in the treatment of oral lichen planus can cause adverse long-term effects in patients. Thus the timely follow up is very essential in the Oral lichen planus patients to avoid the long term use of steroids.[13, 14] Currently the other modalities like calcineurin inhibitors, retinoids, dapsone, have contributed significantly toward treatment of the disease.[8] Though the drugs have a role in treatment, none of them offer a cure for the disease. The lacuane in the treatment of OLP is targeted therapy using the self peptide or HSP. Thus our studies aim to provide foundation for this by experimenting the molecular mechanism of HSP 90 in the Oral lichen planus.

Aim and Objective of the Study:

1. To evaluate the expression pattern of HSP 90 in OLP patients and to compare with normal, controls and those with inflamed mucosa.
2. To quantify the molecular level of HSP 90 gene in the Study groups (Normal, Inflamed and Oral lichen Planus) by real time PCR.

Study Population: Study samples were collected from patients attending outpatient department of Dermatology, Oral medicine and Oral surgery. The research proposal was approved by the Institution of Ethics, SRU in April 2012 (NI/11/OCT/25/64). A written informed consent was obtained from all the patients prior to the procedure. A total of 150 samples were collected from Department of oral medicine, Oral Surgery and Dermatology, Sri Ramachandra Institute of Higher education and research. The slides were reviewed by the research panel. Cases with histopathology oflichenoid reactions were removed from the study groups.

Materials and Methodology

Tissue Preparation: Informed consent was obtained from patients undergoing incisional biopsy. Tissues from oral lichen planus patients with and without skin lichen planus were included. The normal tissue samples were collected from patients who visited the institution for therapeutic removal of impacted teeth. All tissues obtained were reviewed and confirmatory diagnosis were made. Immediately after biopsy, tissue samples were frozen in liquid nitrogen and then stored at -80^0C until RNA was being extracted.

RNA Isolation: The stored samples were thawed and dissolved in Trizol. Tissue homogenization was

done. A portion of the dissolved tissue was transferred to another vial and RNA conversion was done according to protocol. Samples were dissolved in RNasefree water and quantified using Nanodrop. Purity of total RNA was determined by the A260/A280 and A260/A230 ratio, respectively.

Single stranded cDNA Synthesis: The cDNA synthesis was carried out using Prime Script RT Reagent Kit (TAKARA BIO, INC, INDIA). The protocol for the cDNA synthesis was followed. The calculations of the same are mentioned in the table below (Table 1). Each reaction was set at 10µl of which 3.5 µl was used from takara kit and 6.5µl was made of RNA(500 µg) and diluted with RNase free. RNA concentration was calculated based on the nucleic acid concentration obtained during the Nanodrop check. Every sample is expected to have a different RNA quantity based on the nucleic acid concentration. The remaining quantity was diluted to 10 µl using RNase free water. The reaction mixture was incubated under the following conditions: 37˚C, 15 minutes (Reverse Transcription); 85˚C, 5 sec (inactivation of reverse transcriptase with heat treatment); 4˚C.

Levels of HSP90 expression were determined by real-time PCR (RT-PCR). For real-time PCR, hsp90 primers and beta actin primers were used. These primers were blasted by primer- blast site on NCBI website. The forward (F) and reverse (R) primer sequences of hsp90 and β-actin used in real-time PCR were shown in (Table 2). Beta actin was used as the internal control gene. For hsp90, a 66bp amplicon and for beta actin a 648bp amplicon were generated in a 10µl reaction mixture that contained the reagents as showed (Table 3). Each RNA sample was divided into equal amounts and then, HSP90 and beta-actin in parallel with each other were amplified by real-time PCR in triplicate. Negative controls were prepared each time with 2µl DdH2O instead of the cDNA template. Real time PCR amplification was performed using a ABI system with the following setting as manufacture protocol. The reaction mixture was incubated under the following conditions: 95˚C, 2 minutes, 1 cycle (Holding step); 65˚C, 20 seconds, 45 cycles (Annealing); 72˚C, 20 seconds, 45 cycles (Extension); 75-99 ˚C, 1 cycle (Melting).

Statistical Analysis: Statistical analyses were performed with Graph Pad Prism 6.01 software. Results were expressed as the mean±standard deviation (SD). Statistical differences were assessed by 2 way Anova - Bonferroni's multiple comparison test and a value of p less than 0.05 was considered significant. (Table 4 & 5)

Results

Statistical Results: 2-way Anova- Bonferroni's Test

Table 4: Mean Δ C_t of HSP 90 expression amongst the study groups

Results	Normal	Inflamed	OLP
Mean	2.591	2.753	3.184
Standard Deviation	0.6943	0.8364	0.9117

Table 5: Bonferroni's Multiple T-test Results p Value <0.05 was considered significant

Bonferroni's multiple comparisons test	Mean Diff.	95% CI of diff.	Significance	Summary
Normal vs. Inflamed	-0.1619	-0.3685 to 0.04467	Ns	0.87
Normal vs. OLP	-0.5934	-0.8000 to -0.3868	*	0.039
Inflamed vs. OLP	-0.4315	-0.6381 to -0.2249	*	<0.0005

Effects on the gene Expression: The levels of HSP 90 gene expression were measured by Real Time PCR. Changes in the expression levels of the protein between the study groups were normalized to beta actin levels and then calculated by Livak method. As the disease state progressed, the levels of HSP 90 gene expression was increasing accordingly. Real time PCR data analysis signified a gradual increase in the expression from Normal to inflamed and a sharp increase to OLP. The fold changes in comparison to the normal is as shown in the Livak Method in table 6. Using the formula, the fold change seen clearly proves the upregulation of the protein in OLP patients.

Livak Method Formula:

1. Step I:
   - Normalize C_t (Target Gene) to C_t (Reference Gene) = ΔC_t (C_tTarget -C_t Reference)
2. Step II:
   - Normalize Δ C_t of case to C_t of Normal = $\Delta\Delta C_t$ (ΔC_tcase -ΔC_t normal)
3. Step III:
   - Calculate expression ratio/fold change increase $2^{\Delta\Delta Ct}$

Application of the formula for calculating the fold change

- **Normal vs. Inflamed**
  1. Fold change in Normal vs. Inflamed
  2. Mean ΔCt of Inflamed: 2.75
  3. Mean ΔCt of Normal: 2.59
  4. ΔΔCt: 2.75-2.59=0.16
  5. $2^{\Delta\Delta Ct}$ Fold Change=$2^{0.16}$=1.117 (approx. to 1.12)

Therefore it is quantitatively estimated that the HSP 90 gene has a mean fold increase of 1.12 in the tissue samples of inflamed when compared to the normal samples using Real Time-PCR

- Normal vs. OLP
  1. Mean ΔCt of OLP: 3.18
  2. Mean ΔCt of Normal: 2.59
  3. ΔΔCt: 3.18-2.59=0.59
  4. $2^{\Delta\Delta Ct}$ Fold Change = $2^{0.59}$ = 1.505 (approx. to 1.51)

Therefore it is quantitatively estimated that the HSP 90 gene has a mean fold increase of 1.51 in the tissue samples of OLP when compared to the normal samples using Real Time-PCR.

Table 6: Summary of fold change amongst the study groups in comparison to Normal

Inflamed	OLP
1.12	1.51

Discussion

Lichen planus is a chronic mucocutaneous disease of multifactorial etiology and pathogenesis. OLP is considered a potentially malignant lesion, so lesion

monitoring must be periodic even in asymptomatic patients and symptomatic ones should be treated. This chronic lesion is usually detected in 0.5-2.2% of population. Among these, only 0.5-.1.5% of the lesions progress to carcinoma. However, there are no prognostic markers available presently to recognize the increased risk in malignant transformation of the lesions. As well the current therapeutic regimen has The concept linking OLP and oral squamous cell carcinoma states that chronic inflammation results in crucial DNA damage, which further progresses to development of carcinoma. Even though in the past decade, enormous information has been accumulated on malignant potential of OLP, its transformation still remains unclear. This molecular work done in identifying the role of HSP 90 in OLP as a good prognostic marker.

Corticosteroids are considered as first-line treatments since their topical form has better benefits and fewer side effects over time. Alternative therapies efficacy has not been demonstrated yet. These drawbacks make us identify the role of novel molecules that could be a potential target for the treatment of OLP. This study demonstrates and identifies HSP 90 as a novel bio- molecule. Heat shock proteins expressed by oral keratinocytes may be auto antigenic in Oral lichen planus. Susceptibility to Oral lichen planus may result from dysregulated heat shock protein gene expression by stressed oral keratinocytes or from an inability to suppress an immune response following self-Heat shock protein recognition. Over expression of Heat shock protein 90 in Oral lichen Planus has been associated to the persistence or chronicity of the disease, or they could have simply reflected cellular injury. The findings were substantiated with the study done by Bramanti T.E. et al (1995), Yin Cao Shen Li Jia et al (2006) and Ponlatham et al (2009), Yin Cao Shen Li Jia et al (2006) .

Conclusion

The importance in identifying the role of HSP 90 in genomic analysis could provide rich information to help understand the pathology of a disease in an integrated way. Understanding the histology, premalignant state and molecular mechanisms of oral carcinogenesis may facilitate the development of novel strategies for the prevention and treatment of oral cancers arising from Oral lichen planus. This tumor-associated protein can be further evaluated as potential biomarker for pathogenetic investigations.

To our best knowledge in the literature, there has not been any previous studies done in this sample size and tissue samples of OSCC and OLP Patients. This is the first global data to be published on this huge sample size. Though trials are currently happening in finding novel HSP 90 inhibitors, base for OSCC targeted therapy is still unknown and this study enlightens and unfolds the path to attempt HSP 90 in targeted therapy for OSCC patients. Studies on tissue samples are more authenticated and reliable as it directly is related to the patient and the results are validated better.

Conflict of Interest: None declared.

Ethics Statement/Confirmation of Patients' Permission: This study was approved by the Institutional Review Board and all patients provided their informed consent for all examinations and experiments.

Funding Agent: ICMR- TSS Program

A Study to Assess the Attitude of School Teachers Regarding Sex Education Among School Children Inselected Schools at Mangalore

Abdul Muzavir K. V.[1], Akhila K. R.[1], Akshayamol Antony[1], Alby Jose [1], Aleena Jiji[1], Aleesha Thomas P.[1], Janet Prima Miranda[2]

[1]4th Year B.Sc. Nursing Students, [2]Associate Professor, Department of OBG, Yenepoya Nursing College, Yenepoya (Deemed to be) University, Derlakkatte, Mangalore, Karnataka, India

Abstract

Objectives: The objective of the study was to assess the attitude of school teachers regarding sex education among school children and to find out the association between attitude scores and selected demographic variables.

Method: A non-experimental descriptive study was used to carry out the study on assessment of attitude of teachers towards sex education among school children in a private school at Mangalore. Non-probability purposive sampling was used to select 100 sample. A structured attitude scale was used for finding out the attitude of teachers towards sex education. Data were analysed by using frequency, percentage and chi-square test

Result: The result showed that all the teachers had favourable attitude towards sex education for school children. The study also showed that there is no association between attitude scores and selected demographic variables. ($p<0.05$)

The findings of the study showed that among 100 school teachers most of the subjects (38%)were in the age group of 25-29 years, majority of the respondents (80%) were females, most of the respondents (47%) belongs to Hindu religion, majority of the respondents (77%) were married, most of them (56%) are qualified with B.Ed., most of them (35%) have teaching experience of 2-4 years, majority of them (68%) stay in urban area, majority of them (88%) have previous knowledge regarding sex education, most of them (44%) got information from internet.

Conclusion: From the study, reveals that the teachers have favourable attitude towards sex education. Hence, the teachers are the valuable human resources on whose development depends the future of the nation. In order to enhance the attitude of teachers, a publicity programme should be organized..

Keywords: *Schoolteachers, sex education, attitude.*

Introduction

Curriculum is a planned learning activities, that is guided by the schools and it is carried out individually or groups. An effective successful curriculum development should have goal to meet the needs and demands of the society and expectations of the population[1]. School children who experience a sudden change in their body will not be able to accept the changes, so they need adequate knowledge and good attitude towards sex.

Now a days the children are more alert, intelligent and conscious about the facts, that are kept like secret behind them and they are more curious to know the secret. To reveal the secret they depend up on friends, relatives, TV programmes, internet etc. Which may give incorrect information that can spoil their life[2]. In this situation a teacher and provide correct information for children that will make the child free from their doubts and it is useful in their future life. The children who are having disharmony in parent-child relationship will really get benefit from a good teacher.

The survey conducted by SIECUS (Sexuality information and education council of united states) found that, most of the parents believe that sex education in schools help them to communicate easily with their children regarding the matters of sex. They also told that teachers should have good attitude and knowledge regarding sex education to provide clear and adequate knowledge to the children[3]. The role of sex education in students is that it enhance the life of students with appropriate guidance and several problems may arise in their life if not guided adequately and properly[4]. Many studies have shown that, Sexual activities that are dangerous and its complications and consequences are result of decreased knowledge regarding sex, sexual diseases etc[5]…Sex education requires a positive attitude of educational professionals. So that, this study aimed at determining the attitude of school teachers towards sex education. A teacher is the most important person in a curriculum implementation process. School based sex education will be effective way of improving knowledge and attitude of school teachers regarding sex education among school children[6].

Materials and Method

The study was conducted in a school at Mangalore and the school was selected based on the availability of samples and feasibility of conducting the study. Non probability purposive sampling technique was used for the selection of sample. The samples of the study was 100 school teachers. A structured attitude scale was used to assess the attitude of school teachers regarding sex education.

Findings:

Section I: Assessment of attitude of school teachers regarding sex education among school children: The data presented in the table 1 shows that all of the respondents have favourable attitude regarding sex education for school children.

Table 1: Level of attitude of school teachers regarding sex education among school children N=100

Attitude	Frequency (f)	Percentage (%)
Favourable	100	100%
Unfavourable	0	-

Maximum score: 84, Maximum Questions: 21

Conclusion

The study showed that all of the school teachers had favourable attitude towards sex education and none of them have unfavourable attitude regarding sex education among school children and there is no association between attitude score and selected demographic variables.

Ethical Clearance: Yenepoya Ethics Committee-1 approved our study protocol number 2018/074 titled "A study to assess the attitude of school teachers regarding sex education among school children in selected schools at Mangalore" on 31/5/2018 under the chairmanship of Dr. Vikram Shetty.

Abstract

Background: Physiotherapy had provided an invaluable treatment and assistance to the patients. The physiotherapist who provides a home based exercises [HBE] to the patients is one of the most fundamental and important aspect in our daily life. Understanding the facilitators and barriers to home based exercises is most important factor in follow up of any physiotherapy rehabilitation. Hence an attempt was made to analyze facilitators and barriers to home based exercises.

Materials and Methodology: A cross sectional study was carried using self-constructed questionnaire which was validated from institutional professors. Patients coming to physiotherapy OPD were screened.

Conclusion: There was lack of self confidence and motivation for performance for performing home based physiotherapy exercise.

Keywords: *Facilitators, barriers, home based exercises, rehabilitation.*

Introduction

Physiotherapy had provided an invaluable treatment and assistance to the patients. The physiotherapist who provides a home based exercises [HBE] to the patients is one of the most fundamental and important aspect in our daily life. In general, patients adhere was poor to their prescribed home program, with varying estimations. Non-adherence to a home exercises program has showed a high as 50-65% for general based conditions. Another major issue with non-adherence was important to continue with prescribed exercise regime to decrease the risk of recurrent injuries. Patients who did not comply with their prescribed exercises have shown to demonstrate less positive outcome.[1]

Corresponding Author:
Dr. Abha Khisty
Assisstant Professor, Dr. D.Y. Patil College of physiotherapy, Pimpri, Pune-411018
e-mail: abha.khisthy@dpu.edu.in

Non-adherence also gave result to the physiotherapist who believed that there current treatment was not effective and proceeding to unnecessarily modify their program. The physiotherapist who had worked with a patient on improving mobility, strength, endurance, range of motion and joint mobilisation. The therapeutic exercises had greatly reduced stiffness and had caused relief in pain[1]. Patients may also be given exercises to carry out at home to improve strength and flexibility. Self-managed therapy was an increasingly a common element of rehabilitation program for various long term conditions.[2]

Adherence is defined as the extent to which person's behaviour – taking medications, following diet, and/or executing lifestyle changes, corresponds with agreed was also increasingly used in relation to patient self-management of their health.[2] Despite adherence to physical therapy regimes beings recognized as fundamental to positive outcome, there is evidence that non-adherence was often very high. Self - managed HBPT was particularly often demonstrate the lowest level of patient adherence amongst physical therapy modalities.[1] HBPT that failed to achieve either a

certain proportion, or absolute value, of recommended exercise repetition, or recommended exercise duration, or recommended frequency or sometimes a combination of these. Although there might be little consequences regarding what proportion, repetition and frequency should be considered.[3]

Understanding the factors influencing the patient's adherence to HBPT could facilitate the identification of barriers and help practitioners maximise exposure to factors promoting adherence. HBPT was often characterised by a number of features that make it particularly susceptible to non-adherence[3]. These features include the unsupervised nature of treatment, necessitation of lifestyle modification, not providing immediate symptomatic-relief, doubts and uncertainty, about the therapy and potential provocation of the symptoms. Alternatives to self-report are also associated with their own limitation. For eg: in clinical practice, assessments are not necessarily an accurate reflection of unsupervised home practice. Device for objective measurements of exercise adherence such as accelerometers may not capture the movements[4].

In some cases self-motivation refers to individual's tendency to persevere with the behaviour in the absence of external drives. Someauthors established taxonomy where motivation was structured in the form of a continuum that covered the different degrees of self-determination of behaviour[4]. Higher self-motivation and greater intention to complete HBPT exercises also emerged as strong predictors of greater adherence to HBPTs. In self-managed therapy programme relatively free of external motivators, individuals reporting higher intensions and self-motivations are likely to have comparatively high intrinsic motivations. Social support is believed to facilitate adherence via encouraging optimism and self-esteem, buffering stresses of illness and giving practical assistance[5].

Physiotherapy rehabilitation for many conditions includes 'hands on' manual therapy techniques (mobilization, Manipulation or massage) and 'hands off' approaches including postural advice and exercise therapy. Exercise programmes were commonly used but encompass a wide range of concepts. General (fitness) type exercises were conducted on a group basis in either hospital department or sports centre and focus on promoting graded resumption of normal activity. They may be supervised by physiotherapists or fitness instructors and carried out over a set number of weeks, usually for one to two hours per week, in a format similar to cardiac rehabilitation. These interventions have typically been targeted at patients with on-going (chronic) disabling pain[3].

In contrast, specific exercises are also prescribed but these are individually taught. They may follow a specific regimen or be individually tailored. It is common for these exercises to be prescribed on a 'little and often' basis. This means interspersing them with the patient's daily activities, so that by the end of a typical day the patient may have performed several (e.g., more than three and possibly up to ten) bouts of exercise lasting 2 – 5 minutes on each occasion or they have activated postural control muscles prior to undertaking certain activities or tasks. Although monitored by physiotherapists these exercises are unsupervised[6].

Unfortunately, adherence across the range of possible physiotherapeutic exercise is often problematic. In some cases, poor adherence could be the reason for ineffective treatment outcome since it has yet to be established what level of partial adherence is required for beneficial effect. It may also explain the ambiguous research results assessing effectiveness of exercise therapy for pain. The task of the physiotherapist is to improve the patient's condition, by improving not only the ability to recover physical fitness, however the patient is activated not only in the somatic aspect; the patient begins to understand and to see the meaning of his own life, he knows that he becomes active; working on it (if possible) might give him the chance to be more independent and decrease the burden that is taken by someone to improve his health conditions.

The individual is considered in the context of the system (family, community, nation). There should be a proper understanding of mutual expectations, a clear definition of options to help (the availability of specific expertise, specific tools). It is also taken into account not only an external event, environmental, but internal forces (emotions, perception, behaviour). Contemporary view and opinions broaden the range of activities of people supporting the patient. Physiotherapist profession requires, in addition to excellent technical background, knowledge of the condition of the patient, as well as the ability of contact with the patient and understanding what the patient expects from a physiotherapist. Understanding is conceived as understanding of patient's intentions, sensing his/her dysfunction problems, not to interfere too much in the personal life of the patient[6].

Materials and Methodology

Study Design: Cross sectional study

Study Setting: Dr. D.Y. Patil College of Physiotherapy

Target Population: Patients visiting the Physiotherapy OPD for musculoskeletal problems.

Sample Population: Patients suffering from musculoskeletal pain like OA, Mechanical Low Back Pain, Kneeand Ankle Injuries who are visiting Physiotherapy OPD.

Sampling Method: Purposive Sampling

Sample Size: 100

Inclusion Criteria:

1. Age : 18 to 50 years
2. Both genders
3. Participants who are able to follow the commands and are hading to participate in the study.
4. Participants having problem regarding their musculoskeletal pain such as OA Knee, mechanical low back pain knee and ankle injuries, old orthopedic conditions.
5. People with both operative and non-operative cases.

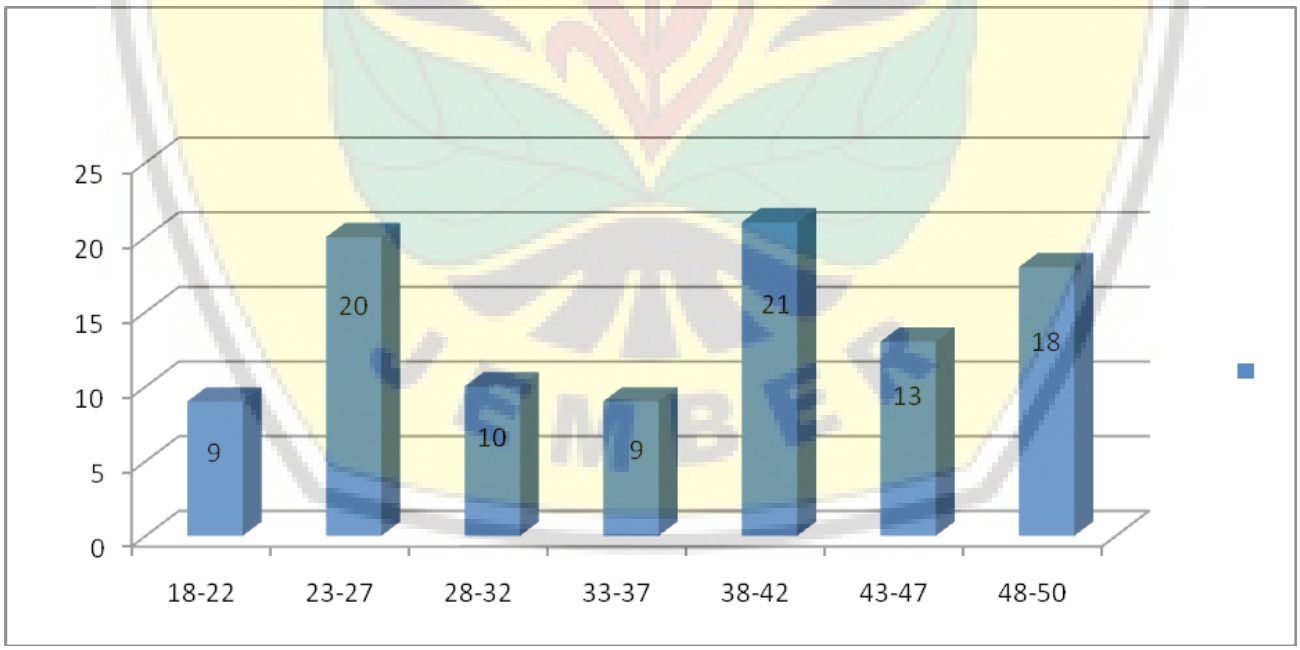
Exclusion Criteria:

1. Participants with trauma and neurological conditions.
2. History of any recent abdominal, back surgeries, Pregnancy, Psychological risk factors.
3. Any contra indication for exercises.

Materials Required:

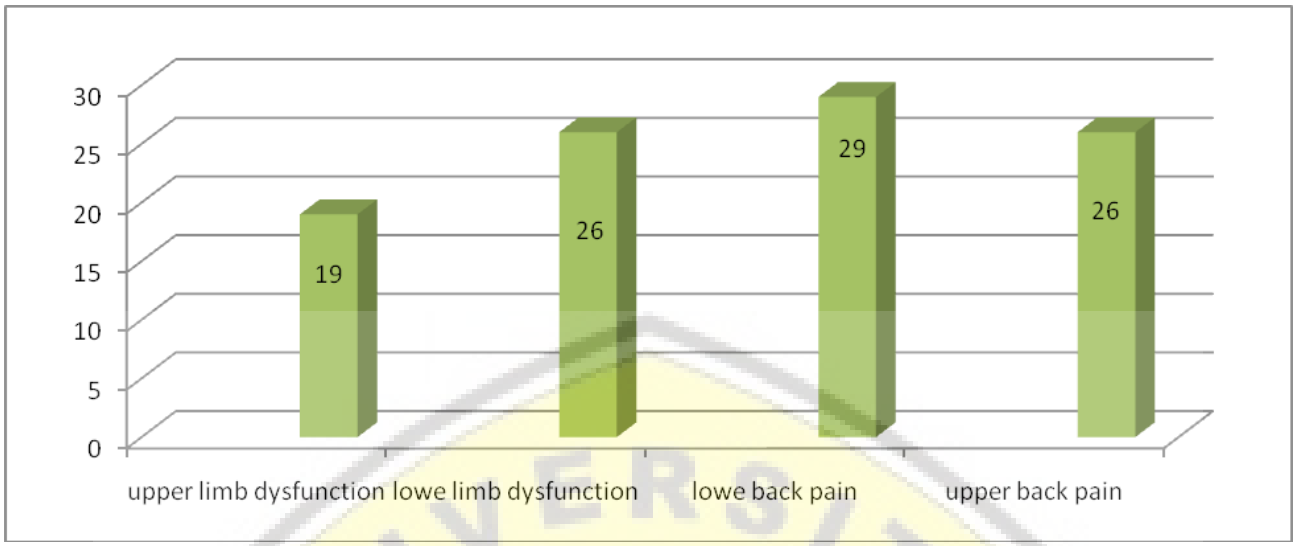
1. Consent form/Questionnaire
2. Pen/Paper

Findings:



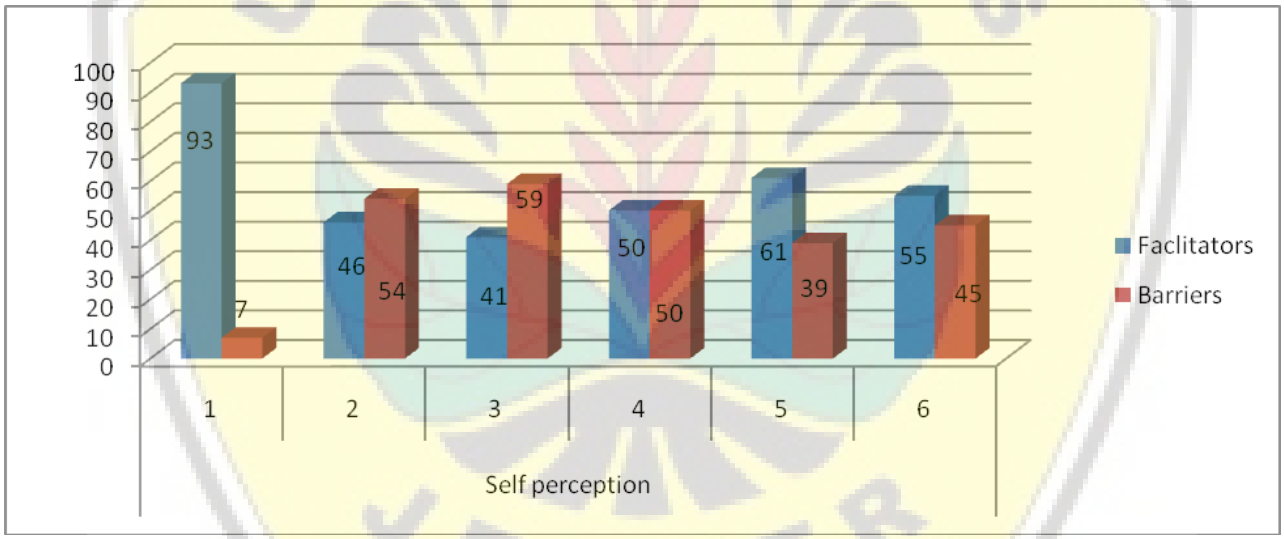
Graph 1: The age group of 18-22 years, 23-27 years, 28-32 years, 33-37 years, 38-42 years, 43-47 years, 48-50 years.

Interpretation: In the Age Group of 18-50. The most affected Age Group was 38-42 years of people.



Graph 2: This graph shows the different types if musculoskeletal dysfunctions that people suffer from.

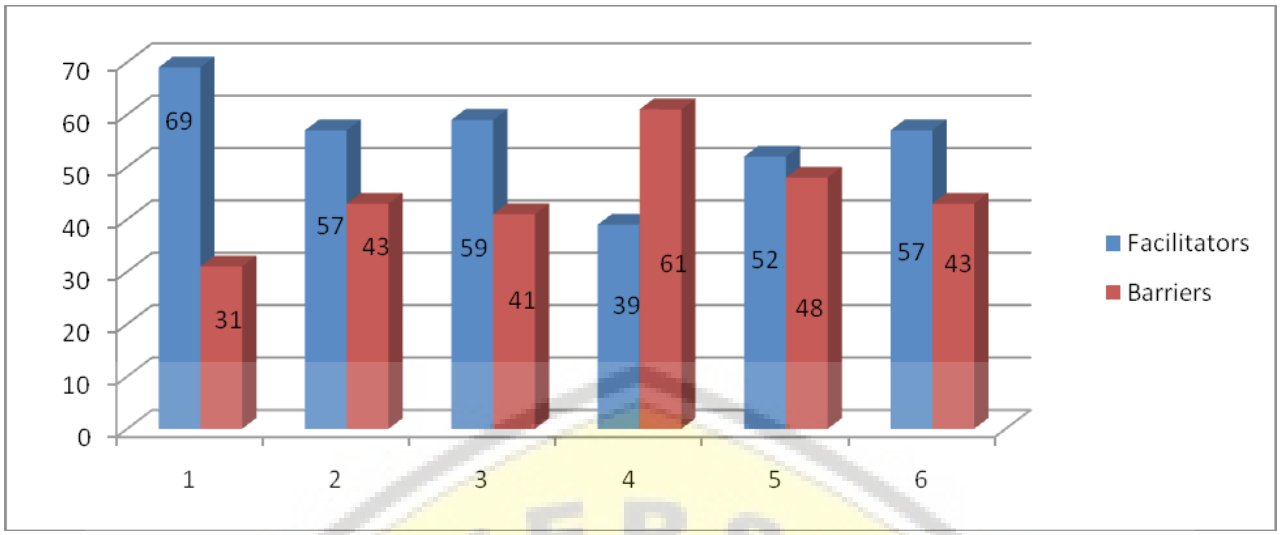
Interpretation: People suffering from different musculoskeletal dysfunction have most common complaint of lower back pain which is 29 in number.



Graph 3: This graph represents the self-perception of Facilitators and Barriers to exercise in Physiotherapy practice

Interpretation:

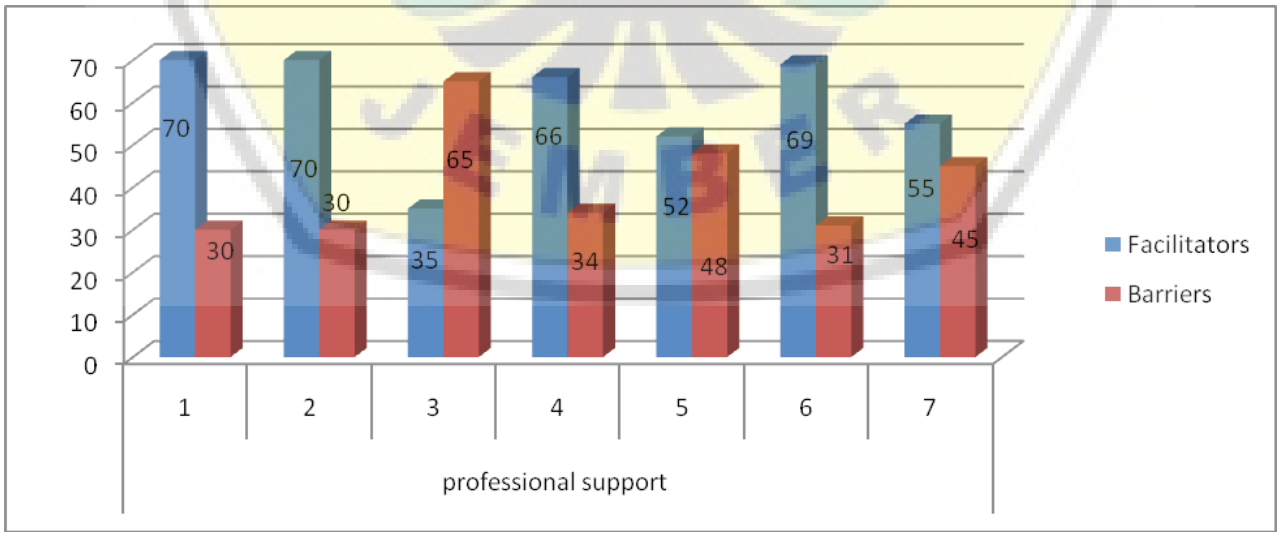
1. 93 number of people are able to do their prescribed exercises at home.
2. 46 number of people do self-monitoring programs.
3. 41 number of people feel on fear of injury while doing home exercises.
4. 50 number of people feel that home program should be supervised.
5. 61 number of people fell that time availability is an important factor.
6. 55 number of people have family members who spend time with them while performing exercises.



Graph 4: This graph represents the social suport of Facilitators and Barriers to exercise in Physiotherapy practice.

Interpretation:

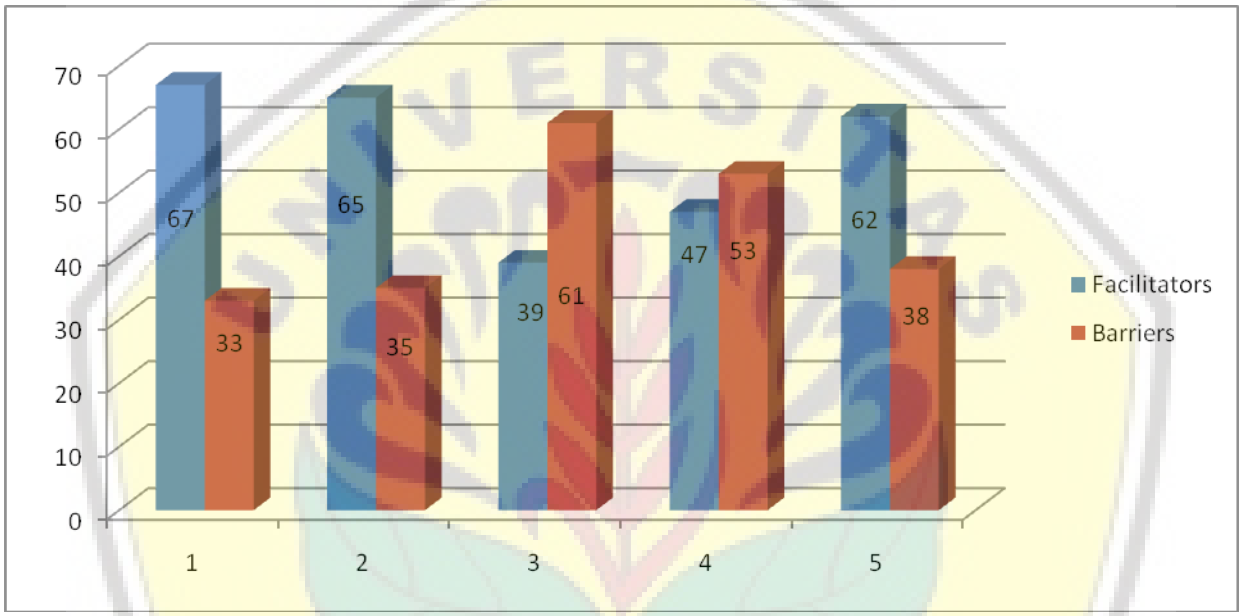
1. 69 number of people are having the task appreciation on added advantage of increase exercises.
2. 57 number of people feel group activity is a good option for home programs.
3. 59 number of people feels friends and family support increases their interest in exercises.
4. 39 number of people feel that their exercises don't get affected while exercising.
5. 52 number of people feel that doing daily exercise makes them feel tired.
6. 57 number of people feel that doing daily exercises make them feel fresh.



Graph 5: This graph represents the professional support to Facilitators and Barriers to exercises in Physiotherapy practice.

Interpretation:

1. 70 number of people feel prescribed programs are easy to understand and perform at home.
2. 70 number of people feel prior training of exercises at physiotherapy department increases the quality of exercises and adherence.
3. 35 number of people feels quality and personality of physiotherapist affect exercise.
4. 66 number of people feels that the set goals by physiotherapist are achievable at home.
5. 52 number of people feel that the physiotherapist should discuss their set goals.
6. 69 number of people feel should explain the reason of all the HBE program.
7. 55 number of people feel that the physiotherapist should get involved in home based rehabilitation protocol,



Graph 6: This graph represents the infrastructure of Facilitators and Barriers to exercise in Physiotherapy practice

Interpretation:

1. 67 number of people feels that the required equipment are easily available for them.
2. 65 number of people prefer performing exercises at home then the physiotherapy department.
3. 39 number of people thinks that the environmental issues affect their exercise performance.
4. 47 number of people have a limited space at home which is the problem to perform daily prescribed exercises.
5. 62 number of people don't have fear of damage of infrastructure at home that limits their exercise program.

Discussion

This study was done to find the awareness among the people regarding the facilitators and barriers that they come across when they perform exercises at home. There were many of them who were aware of the facilitators and barriers that they were facing in their daily life schedule. The study had helped to upgrade and promote occupational health at those set ups by proper evaluation of risk factors at work and provided a better treatment goals and fasten recovery. The study had helped to increase the knowledge regarding HBPT-exercises and helped in improving the confidence. The study helped in increasing the level of patients adherence towards exercises and a physically active lifestyle.

In this study Self-Perception gave a comment that there are 4 components which act as facilitators and have a positive outcome. Like there are people who like to do the prescribed, then there are some who do self-monitoring exercises. Some of them think time availability is the important factor to do home based exercises, some have family members who spent time with them while doing exercises. There are 2 components in which act as the facilitators and people feel that while doing exercises at home they don't have fear of fall or fear of injury and some of them feel that they don't require supervision while performing exercises at home.

In this study Social Support had outcome measures in which the 4 components are facilitators and have a positive effect. When people perform exercisestask appreciation on completion of the set goals add advantage in increasing the exercise volume, whereas some of them think that group activity is a good option for home exercises. Some of them think that the family and friends support increases their interest in exercises at home,some feel that doing daily exercises make them feel fresh. There are 2 components in which people have feeling that their ADL's don't affect their exercise program and some of them feel that daily exercises makes them feel tired.

In this study the Professional Support gave outcome that there are 6 components are facilitators and a positive effect. There are many number of people who think prescribed programs are easy to understand, some think prior training in the physiotherapy department is necessary, some think that the set goals by the therapist are easily achievable at home, some have the feeling that the physiotherapist should discuss the set goals for training, where else some think that they should know the reason of advantages of all the exercises and some of them feel that the therapist should be more clear and should get involved in home based rehabilitation protocol. There is only 1 component that says the quality and personality of the therapist don't affect their exercises quality.

In this study Infrastructure gave a comment that there are 2 components in which the people feel that the equipment required at home for exercises in easily available and some of the feel performing exercises at home is then at doing them at department. There are 3 components in which people have a feeling that the environmental issue does not affect their exercises at home, some of them feel that limited space is not the issue for doing the prescribed exercise at home and some of them think that fare of damage of modalities and infrastructure does not limit their exercising at home.

This study was done by Selina M. Parry had discussed in his study that the largest body of research synthesised to date on this topic we have identified that the barriers to PA for survivors of critical illness are diverse and span five major: (1) patient physical and psychological influences; (2) safety influences; (3) culture and team influences; (4) motivations and beliefs regarding the benefits and risks of PA; and (5) environmental influences. Our review is unique in that we have examined this issue across the care pathway from ICU to community. Many of the barriers and enablers identified were consistent across both quantitative and qualitative study design and across different geographical settings worldwide, thus improving the generalizability of findings[10].

According to the study the most of the people were well known about the facilitators and barriers they face while performing the told exercises at home and many of them tried to modify their exercises.

Conclusion

This study concluded that there were participants who were able to do prescribed exercises at home and were also able to do exercises with self-monitoring. They also had no fear of injury or aggravation of problems while exercising. Some of them didn't have a feeling of supervision of the home programs. Some thought time availability was an important factor, where else some felt that family members who spent time with them helped in increasing the quality of exercises.

This study also concluded that the task appreciation on completion had added advantages in increasing exercise volume, on the other hand some felt that group activity was a good option for a home based exercises. Some of the participants felt that friends and family support increased their interest in exercising and some felt that their ADL's don't affect their exercise programs. For some participants exercising is tiring and for some it was refreshing.

Effect of Quality of Sleep on Agility in Young Collegiate Cricket Players

Ahmed Raza[1], Prachi Tiwari [2], Zuheb Ahmed Siddiqui [2], Junaid Jameel[3]

[1]BPT Intern, [2]Assistant Professor, Department of Rehabilitation Sciences, Jamia Hamdard, [3]Physiotherapist, Dr. Baba Saheb Ambedkar Hospital, Rohini, New Delhi

Abstract

Introduction: Sleep is a strategy that contributes to significant recovery from multiple fatiguing events, including both cognitive and physiological tasks and is an influential factor in avoiding overtraining. Sleep deprivation leads to poor performance, reduced motivation and arousal levels and reduced cognitive processes leading to poor attention and concentration and heightened levels of perceived exertion and pain perception; limitations to physiological processes include disrupted glucose metabolism and neuroendocrine functioning, a compromised immune system and reduction in cardiovascular performance.

Approach: Male Cricketers aged between 20 – 30 years having normal body mass index (BMI) were selected for the study. Pitts Burgh Sleep Quality Index (PSQI)was administered and Zig-Zag test was performed for agility testing.

Result: Statistical analysis was done by using SPSS software, Version 20. Pearson's coefficient of correlation was used to find out the effect of quality of sleep on agility in young cricketers. The data analysis shows that there is no correlation exists between the sleep quality and agility.

Conclusion: Our study suggests that there was no significant effect of quality of sleep on agility in young cricketers. So, with our study we can conclude that sleep doesn't have any effect on agility performance and in turn to the physical performance in cricket.

Keywords: *Quality of Sleep, Agility, Cricketers, Male.*

Introduction

Sleep is defined as an altered state of consciousness[1]. It contributes to significant recovery from fatiguing events, including both cognitive and physiological tasks and is one of the important factors in avoiding overtraining. Poor sleep quality leads to poor performance, reduced motivation, poor attention and concentration and reduced cognition. Sleep deprivation is considered common amongst athletes, where sleep duration and quality is often neglected when optimizing recovery and competition performance. This alludes to the need for greater athlete education surrounding this subject because subsequently, sleep deprivation leads to disruption of training intensity and performance at competition.[2]

Sleep is very important for athletes as it provides an opportunity for the body to recover from training and to prepare for competition day. General recommendations suggest that 7 to 9 hours of sleep is adequate for psychological (ability to learn, motivation and memory) and physiological (metabolism and inflammation) recovery. Additionally, it has been suggested that athletes require a greater quantity of sleep to recover sufficiently from injury, intense training periods and competition.

Corresponding Author:

e-mail: prachitiwari005@gmail.com

High-performance team-sport athletes endure numerous physiological, psychological and neuromuscular stressors during training and competition[3]. Logically, these athletes balance these stressors with appropriate recovery to maximize performance and adaptation, while also minimizing injury risks[4]. A crucial part of this stress-recovery balance is the management of an athlete's sleep, especially during intense training and competition[5]. Three key factors determine the recuperative outcome of sleep: duration (total sleep time), quality and phase (circadian timing) of sleep[6].

Agility is the ability to move and change direction and position of the body quickly and effectively while under control[7]. This ability is a determinant of performance in the field and court games, evidenced by time-motion analysis and coaching analyses for various team sports. This is an important component of many sports training programs. Improved agility can mean better performance, faster response and give athletes an edge over their competition[8]. A sports person requires it when actions are to be combined or when a movement has to be performed by changed and unaccustomed conditions. It is required to a great extent in cricket involving efficient footwork and quick changes in body position.[9]

Cricket is one of the most popular sports within ex-British Colonial countries around the world. The physical demands of cricket involve short sharp periods of intense activity, characterised by explosive actions such as bowling, batting and fielding. Many scholars have considered the ability to change direction quickly as an integral part of athletic performance. More specifically, the ability to change the body's position quickly and effectively in response to a stimulus is crucial in almost all sports. Within cricket, high agility levels and quick reaction times are key concepts held by most players who excel at their skills. Indeed, clear advantages can be seen by performers who have high fitness levels and physiological health profiles[10].

Methodology

The present study was conducted in Sports Ground, Jamia Hamdard, New Delhi. A screening list was administered and only those subjects were considered for the study that fulfilled the inclusion and exclusion criteria. Using a sample of convenience, 40 male cricket players aged 20-30 years, having normal BMI were included in the present study. Subjects having any sort of visual or motor impairment, amputees, any recent treatment for neck, thoracic and lumbar disorders, any sort of neurological disorders and any sort of psychiatric disorders were excluded from the study. Subjects were asked to sign an informed consent. The exclusion criterion was ruled out one by one by taking the subject's history.

The agility of the subjects was tested using the Zig-Zag test. In the Zig-Zag test, a rectangle of 10 x 16 feet was made with four cones and one cone is placed at the centre of the rectangle. Subjects have to complete one circuit of the course in the shortest possible time, starting and finishing from start and finish cone respectively. The time taken by subjects to perform the test was recorded.

Sleep Quality assessment was done by administrating Pitts Burgh Sleep Quality Index (PSQI). PSQI has seven components namely, subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, sleep medication and daytime dysfunction. The score of component ranges from 0 to 3 and are added to obtain a total score which ranges from 0 to 21. The total score is obtained by adding a score of all seven components. A higher score indicates poor sleep quality.

Data Analysis: Data analysis was done using Pearson Correlation test to find the effect of quality of sleep on agility in young to find out the effect of quality of sleep on agility in young collegiate cricket players. A statistically significant difference was defined as a p-value of less than 0.05.

Result

Table 1: Descriptive Statistics

	Mean	Standard Deviation	N
Age	21.85	3.062	40
Height	172.5	5.27	40
Weight	65.95	7.91	40
BMI	22.07	2.19	40
PSQI	4.43	2.31	40
Agility	7.99	0.77	40

Table 2: Correlation between sleep quality and agility

	Agility		
	Correlation Coefficient	N	Sig.
PSQI	0.028	40	0.862

A total of 40 male subjects participated in the study. Their demographic data were analyzed by comparing means of descriptive analysis. Their age, height, weight and BMI was recorded (Table 1). The mean age (in years) was 21.85±3.06. Table 1 gives details of the mean and standard deviation of these data. The Mean value of sleep quality was 4.43±2.31 and agility was 7.99±0.77. A statistically non-significant difference exists between sleep quality and agility in young collegiate male cricketers (Table 2).

Discussion

The objective of the present study was to find the effect of sleep quality on agility in young collegiate cricketers. The data analysis shows that no correlation exists between sleep quality and agility. Various factors affect agility with Body Mass Index being one of them. The result of our study is in continuation with the study done by Shafizadeh (2010) who evaluated the relationship between anthropometric parameters and individual skills in young school football players[11]. The results demonstrate that an inverse relationship exists between body weight and running skill, which means higher the body mass index, less is the running speed and weaker is the sport performance. Taghinejad found that there is an inverse relationship between body composition and performance in soccer[12,13]. Since subjects in our study have a normal body mass index therefore, no correlation with agility was obtained. Rahul et al did a comparative study of fitness variable of junior and senior cricket players. He founded that senior cricketers have better agility performance in comparison to junior cricketers[14]. Since we have included young cricketers in our research study so this explains why we have obtained this result.

Various pieces of literature have shown that plyometric training has a significant effect on improving agility. Miller et al did a study to find the effect of plyometric training on agility in six weeks. Their results demonstrated a significant improvement of agility in the experimental group throughout six weeks[15]. Most of our subjects did not undergo any plyometric training programme hence, no significant result was obtained.

During the off-season, cricketers have ample time to plan and execute individual programs to improve their desired physical qualities to improve performance [16, 17]. Strength and power are the qualities which are majorly considered[18]. The same programme is adopted by subjects in our study and so no improvement in agility is obtained. Various studies have shown that batsmen have better agility as compared to bowlers[19]. It is because of the medium body structure of batsmen as compared to bowlers. They can move their body very fast and easily [20]. Hence, there exists a significant difference between batsmen and bowlers on physical fitness variable agility.

Conclusion

To conclude, our study suggests that there was no significant effect of quality of sleep on agility in young collegiate cricketers. So with our study, we can conclude that sleep doesn't have any effect on agility performance and in turn to the physical performance in cricket.

Future Research: Future researches can be done by correlating sleep with other factors affecting sports performance and various age groups of cricketers can be compared to find out the correlation of sleep with agility.

A Peek into Contributing Factors and Impact of Voice Problems among Teachers in Chennai: A Bio Psychosocial Perspective

Aishwarya Nallamuthu[1], Prakash Boominathan[2], Ravikumar Arunachalam[3], Pushpavathi Mariswamy[4]

[1]Assistant Professor, [2]Professor & Head, Department of Speech Language & Hearing Sciences, Sri Ramachandra Institute of Higher Education & Research, [3]Director, Clinical Services, Dept. of ENT & Head and Neck Surgery, Sri Ramachandra Institute of Higher Education & Research, [4]Director, All India Institute of Speech and Hearing, Manasagangothri

Abstract

Background: Compromised vocal health in teachers affects their quality of life. Magnitude of voice problem varies depending individuals' perception and their adaption to existing condition. This study focused on analyzing the contributing factors of voice problems from a bio-psychosocial perspective (using WHO, ICF framework) and its impact on teachers.

Method: A vocal health questionnaire that included sections on personal factors, voice use, vocal symptoms, activity limitations and environmental factors was developed and administered on 105 teachers. Frequency analysis and odds-ratio was used to report the presence of voice problems, contributing factors and its impact on daily situation.

Findings: Teachers faced considerable impairment in body function (such as tiredness after speaking, throat pain, & feeling upset). As a result, it posed significant limitation in communication with family/friends and engaging in social/religious ceremonies. Though teachers had positive support from their colleagues and society,noisy classrooms and tropical weather had an adverse consequence on the quality of life of teachers. These details are vital to design and implement vocal hygiene programs. They could also serve as prognostic indicators in vocal habilitation.

Keywords: *Teachers, vocal health, participation restriction, contextual factors.*

Introduction

A voice disorder exists when the vocal functioning of an individual no longer meets the voicing requirements[1]. Voice problems are more common in teachers[2–4] and the severity may vary based on occupational demand. For instance, a teacher with hyperfunctional voice disorder may face limitation while lecturing in the presence of increased noise. However, he/she may have minimal difficulty while speaking in a quiet room. Persistent voice problem may result in reduced work performance, altered/impaired social life, absenteeism and financial loss[3,5–7] Though voice disorders are not fatal, its impact on teachers is found to be parallel to impact from life threating conditions[8]. Therefore, it is essential to understand voice problems from the teachers' perspective.

Subjective vocal symptoms and its impact on their day to daily life can be best obtained by patient self-reports. Several such patient related outcome measures (PROMs) have been developed to understand the impact of voice problems from an individuals' perspective[9].

Corresponding Author:
Aishwarya Nallamuthu
Assistant Professor, Department of Speech Language & Hearing Sciences, Sri Ramachandra Institute of Higher Education & Research, India
e-mail: aishwarya.nallamuthu@sriramachandra.edu.in

The Voice Disorder Outcome Profile was developed (in Kannada & Tamil) as a culture specific tool to address the quality of life for individuals with voice disorders in India[10,11]. Profiling of the vocal symptoms were done using Voice Symptom Questionnaire (2003) and Screening Index for Voice Disorders in teachers (2013). Voice Activity and Participation (2001) and Work Productivity Activity Impairment Questionnaire (2014) provide information on activity/participation restriction. In addition to the reported symptoms and activity limitation, it is also essential to understand the role of contributing environmental factors (that acts as a barrier & support) for voice use in teachers. This study aimed to understand self-perception of voice problem and the impact of contributing factors from a bio-psychosocial perspectivein school teachers using the WHOs-International Classification of Functioning, Disability and Health (ICF) framework as a guide.

Method

The study was approved by the institutional ethical committee of Sri Ramachandra Medical College & Research Institute (Reference number: IEC-NI/13/AUG/35/64).

Development of vocal health questionnaire: The vocal health questionnaire for teachers was developed based on previous literature and the components of ICF framework. ICF codes under body functions, activities limitation/participation restriction and environmental factors relevant to voice disorders were included. The experts (three speech pathologists and one otolaryngologist with expertise in voice care) were instructed to indicate how relevant each ICF code was with respect to the voice disorder in teachers. Relevance of each code were rated between 'not relevant' (score 0) and 'very relevant' (score 4). Codes which were scored greater than or equal to 3 by 80% of experts were considered and the remaining codes that were not relevant were excluded. Based on the response of the expert team, the vocal health questionnaire was constructed with the following sections.

I. **Personal factors & general health:** Demographic information, educational qualification, total years of teaching, grades taught and details on health related issue

II. **General questions related to voice use:** Open ended questions related to awareness of their voice problem and voice use were included. Frequency of throat clearing, cough, whisper, mimicry and screaming/shouting was documented using a likert scale.

III. **Concept of vocal health and non-vocal practices:** Description of vocal health was included to understand the knowledge and idea of teachers regarding vocal health. This section also included details on non-vocal practices followed by the teachers.

IV. **Vocal symptoms related to body functions:** This section documented the presence and absence of vocal symptoms reported by the teacher.

V. **Vocal functions related to activity limitations/ participation restriction:** The impact of voice problem on day to day activities and participation restriction were included. Section V was divided into environmental factors as barriers and supporting elements for voice use.

Administration of vocal health questionnaire: The questionnaire was distributed to teachers from various schools (from 15 political zones) of Chennai. Informed consent was obtained from the participants. Out of the 150 questionnaires distributed, response was obtained from 105 school teachers (70% response). Frequency analysis was carried out to estimate vocal demand, presence of voice problem, vocal and non-vocal practices, activity/participation in daily situation and contributing environmental factors. Chi-square test was used to estimate the differences in response across sections. Odds ratio was calculated to estimate the risk of developing voice problems consequent to vocal and non-vocal practices, to understand the impact of voice problems and contributing environmental factors on quality of life.

Results

Ninety nine (94.3%) female teachers and six (5.7%) male teachers participated. Teachers ranged from 22 to 65 years with a mean age of 41.05 years (±9.96). They had a wide teaching experience that ranged from 2 to 35 years (mean=10.49 years, SD=8.24). Seventy five teachers (71.4%) did not report of any health issues. of the remaining, fifteen teachers (14.2%) reported of thyroid problem and 18 (17.1%) encountered symptoms of acidity (burp, & burning sensation in the chest region). Teachers who reported of acidity were 4.214 times likely to develop voice problems. Pulmonary/respiratory related disease were reported by six teachers (5.7%).

Vocal symptoms reported by teachers: Compromised vocal health impacts the body functions resulting in vocal symptoms (Table 1). Vocal fatigue was the major voice symptom followed by a voice change and throat pain. Teachers who reported of voice problems were 9.068 and 3.581 times likely to have vocal fatigue and changes in voice respectively. Teachers who reported of voice problems were 3.598 times facing difficulty to speak soft and 3.182 times expected to have struggle for breath while speaking. Teachers who reported to have sticky sensation in the throat reported of intake of lozenges. Voice symptoms resulted in sleep disturbances and psychologically impacted the emotional state by making them upset & less confident. Teachers who reported of voice problems were 2.614 times likely to be irritable and 2.500 times likely to feel upset.

Impact of voice problem on activity limitation/ participation restriction: Teachers who reported voice problems experienced limitations in executing activities and restricted their participation in daily life (Table 2). They faced difficulty in talking over telephone and while interacting with strangers, friends and family members. Teachers were prone to have difficulty in handling stress at home (odds ratio:3.598) and at work (odds ratio:5.714). As a result, teachers who reported of struggle for breath while speaking were 2.630 & 3.533 times likely to avoid social ceremonies (like marriages) and religious ceremonies (like poojas & prayers that involved reciting religious hymns) respectively. Teachersfaced difficulty in maintaining their job and earning sufficient income creating a financial burden. These indicated that voice problems in teachers had a negative influence on communication, emotional state and personal/social life.

Contributing factors for maintaining vocal health: Environmental factors that facilitate (support) or hinder (serve as a barrier) vocal health in teachers are presented in table 3 and table 4 respectively. Speaking in the presence of noise was a major barrier for teachers with voice problems (odds ratio:7.241). In India, intake of certain foods like citric fruits, cold drinks & sour food items (odds ratio:3.340), teaching in presence of chalk-dust and environmental pollutants (odd ratio:7.917) were the major barriers for voice use in teachers. Factors that facilitated vocal health in teachers is profiled in table 5. The role and involvement of family and friends had a positive effect on teachers. Though, they felt that the attitudes of their colleagues, friends and family were supportive. However, they did not have support for undergoing treatment due to personal and logistic issues.

Table 1: Voice symptoms related to body functions

Symptoms	Impairment			p-value
	Present (%)	Absent (%)	NA (%)

Discussion

Teachers are often forced to use continuous loud voice to meet professional demand that in turn affects vocal health[3,12] voice-demanding activities, family history of voice disorders and children at home. Voice problems in teachers have a significant impact on their quality of life[12] voice-demanding activities, family history of voice disorders and children at home thus escalating it as an occupational safety/public health issue[6]. The present study aimed to understand the impacts of voice problem

in teachers from a bio-psychosocial perspective. School teachers from various parts of Chennai participated. Similar to previous literature, a majority of the responses were from female teachers[3,13] Teachers reported a wide range of teaching experience making them vulnerable to develop voice problems[2]. Teachers who encountered symptoms of acidity were at risk of developing voice problems[14]. They consumed lozenges (which is proven it to be an unhealthy practice to vocal health)to get an immediate relief.

Voice symptoms related to body functions and its impact on activity/participation restriction: A variety of impaired body function such as vocal fatigue, changes in voice quality, pain in throat, inability to speak soft and voice breaks were faced by the teachers[15,16]. In addition to these organic symptoms, teachers reported of sleep disturbance that made them upset. As a result of compromised vocal functioning, they reported limitation/restriction in using telephone and personal interaction with other people. In this era of mobile technology and interactive voice response (IVR) world, people interacting with computerized systems and long distance communication is part of a work ease/culture. However, teachers restrict the use of these technologies due to their voice problems. During pooja (act of worshiping) and religious ceremonies, people tend to experience dry throat, cough and changes in voice as a result of reciting prayers for a long time and inhaling fumes from the homam (Hindu ceremonial ritual)[17]. Since these factors aggravate the voice related problems, teachers limited their participation in religious and social ceremonies[18]identifying etiologic factors of dysphonia, voice symptoms, vocal qualities and laryngeal lesions. Eighty teachers were divided into two groups: GI (without or sporadic symptoms, 40.

In India, the salary for teachers in private school is comparatively less than in government schools[19] and they don't have the provision for pension after retirement. This creates a dissatisfaction among teachers that they are unable to meet their basic needs[20] and they engage in private coaching/tuition for additional earnings[3]. Therefore, teachers tend to use their voice continuously after school hours to meet their financial demands. When teachers are unable to meet their occupational demand, they tend to avail sick leave or quit their profession.

Contextual factors for voice problems in teachers: Environmental and personal factors may either hinder or promote voice health in teachers.[15] Teaching in the presence of background noise (that increased the vocal load) and exposure to chalk dust were inevitable barriers in Indian scenario. As a result, teachers developed the habit of throat clearing which in turn would increase the strain in the laryngeal mechanism further leading to voice problems in teachers. Teachers reported a positive effect and support from friends and family indicating that they were not isolated/deprived of jobs/ roles despite noticeable voice issues. Teachers tend to accept voice problems as a part of their profession and tend to cope/sort to home remedies as a first line of treatment[3]. Restriction in availing leave, requirement to complete the curriculum, involvement in additional coaching/training, dearth of awareness about voice-care professionals, lack of support for child care, travel and financial constraints for seeking treatment could restrict them from availing treatment. These details are essential for implementing vocal-hygiene program for teachers in Indian scenario.

Conclusion

Vocal health is multi factorial. The effect of compromised vocal health in teachers is not restricted to the functioning of the vocal system. It extends its impact on the functioning of the individual in everyday situation which can be supported or hindered by environmental factors. This study enlisted the contributing factors and helped realize the impacts of voice problems on quality of life in teachers.

Socio-demographic Determinants of Fertility and Under-five Mortality: A Cross-sectional Study on the Oraons of Alipurduar District, West Bengal, India

Akash Mallick[1], Subrata K. Roy [2]

[1]Senior Research Fellow, [2]Profesor and Head, Biological Anthropology Unit, Indian Statistical Institute, Kolkata, India

Abstract

Background: In India, population diversity plays a major role to create variation in socio-demographic, cultural and lifestyle factors which contribute to unique demographic scenario among populations. However, not much emphasis has been given to investigate the relationship of socio-demographic factors with fertility and mortality scenario among indigenous groups of northern West Bengal. Objectives: Study attempted to see the effect of socio-demographic factors on women's fertility and under-five mortality among the Oraons. Materials and Method: Data on socio-demographic characteristics, fertility and mortality were collected from 445 ever-married women. Descriptive statistics, binary logistic regression and Cox proportion hazard analysis were performed. Results: Total fertility rate in the study group was 3.19 live births per woman and under-five mortality rate was 9.77 death per 100 live births. Educational status of women (p=0.002), household size (p<0.001), age (p=0.001) and marital age of women (p=0.020) significantly determined women's fertility. Educational status of women (p=0.034), women's practice of defecation (p=0.014), Marital age of women (p=0.046) and birth order of the child (p=0.031) significantly determined under-five mortality. Conclusion: Study highlighted that women married before 18 years and with no institutional education were more likely to experience high fertility and high under-five mortality. Absence of pit latrine in household and child's birth order also significantly determined under-five mortality.

Keywords: *Child death, Fertility differentials, Indigenous population, Survival analysis, Cox regression.*

Introduction

Sustainability and well-being of a population reflects on its' demographic measures like fertility and mortality.[1,2] These demographic measures show a complex causal-effect relationship with both genetic and non-genetic factors[3-7] among which socio-demographic factors play key roles.[6,7] Current scientific knowledge showed that variation in socio-demographic factors among populations results in fertility and mortality differentials.[8-15] In the case of India, socio-demographic variation is huge due to enormous population diversity. The country accounts for one-fifth share of world's total birth and also largest share of under-five mortality while it is currently lagging behind to reach the Millennium Development Goals (MDG) and Sustainable Development Goals (SDG).[1,16,17]

Despite a considerable number of demographic studies in India[18-22] there is a dearth of knowledge about the determinants of demographic measures among the indigenous groups of northern West Bengal, living in poverty. [23-25] It is necessary to bring forth unidentified contributing factors that are likely to influence their fertility and child mortality. [26] In this context, present study attempted to explore the socio-demographic

determinants of women's fertility and under-five mortality among the Oraons of northern West Bengal, India.

Materials and Method

Before conducting the research, ethical clearance was obtained from the 'Ethical Committee for the Protection of Research Risks to Humans' of Indian Statistical Institute (Ethical Clearance number: ISI-IEC/2018/10/01). The present cross-sectional study was conducted during Mar-Apr, 2018 in a rural tea garden area named 'Tasati' under Falakata block of Alipurduar district, West Bengal. It included study participants only from Oraons in order to eliminate the genetic/ethnic effect (s) in the data. A list of all adult ever-married Oraon women were made before survey.

Total enumeration was aimed in order to include all the adult women (Aged 18 and above). Initially, a total of 532 healthy adult ever-married women (Who attended menopause, widowed or separated and reported sterilization through operation) were informed properly about the purpose of the study and approached to participate. Finally, 445 ever-married women voluntarily agreed to participate. The informed consent was signed by them and in case of non-literate women, thumb impressions were obtained. All the data were collected by a single investigator. Data on socio-demographic characteristics were collected using a pre-tested schedule [13]. Study participants were asked to provide information on age, number of pregnancies, live birth of child and corresponding age of mother, birth order and detailed information of the child, number of miscarriages and still-births, survival status of child (Dead/Alive) and deceased child's age at death (in month). Age of women was taken either from existing records and/or referring to important local events. Rest of the data include educational status, occupational status, age at marriage, household size and women's practice of defecation. Under-five mortality was considered as the death of a child under 60 months.

Binary logistic regression was performed to calculate the odds ratio (OR) to find out the effect of socio-demographic characteristics on women's fertility. 'Fertility' was considered as binary dependent variable ('Low' and 'High'). Lastly, cox proportional hazard analysis was performed to calculate the hazard ratio (HR) to find out the effect of socio-demographic characteristics on under-five mortality. The dependent variable was 'Survival time' (Deceased child's age at death) and independent variables were educational status, occupational status, household size, presence/ absence of pit latrine, age at marriage, age at child birth, sex of child and birth order of child. All the statistical analyses were performed in PASW 18.0.

Findings: Present study tried to find out the socio-demographic determinants on women's fertility among the Oraons. Table 1 presented binary logistic regression analysis on women's fertility in respect of selected socio-demographic characteristics. Results indicated that women who were 'non-literate' (OR=3.060, 95% CI: 1.175-7.973) or married under 18 years (OR=1.994, 95 & CI: 1.117-3.561) were more likely to show high fertility compared to their counterparts. Women showed higher chance of high fertility with increasing age (OR=1.123, 95% CI: 1.094-1.152). A negative association was found between high fertility and 'low' household size (OR=0.192, 95% CI: 0.106-0.306). Also in the Model IV (Nagelkerke R^2 = 0.515) of 'Stepwise' method, educational status, age of women at marriage, age of women and household size significantly predicted women's fertility.

Results of cox proportion hazards regression of under-five mortality in respect of selected socio-demographic characteristics is presented in table 2. Result indicated that children of both 'non-literate' women (HR = 2.188; 95% CI: 1.060-4.515) and women married under 18 years (HR = 1.304, 95% CI: 0.916-1.857) were at greater risk of under-five mortality. Women who practiced open defecation had a greater risk of children's under-five mortality (HR = 1.846, 95% CI: 1.134-3.005). Also in Model VI of 'Stepwise' method, traits like educational status, women's practice of defecation, age of women at marriage and birth order of child significantly predicted the risk of under-five mortality.

Discussion

In India, demographic measures maintain a complex causal-effect relationship with biological and socio-cultural factors due to enormous population variation.[27,28] However, not much emphasis was given to indigenous groups of northern West Bengal to understand such relationship. Present study aimed to understand the relationship of fertility and under-

five mortality with socio-demographic characteristics. Findings are highlighted subsequently in this section.

The total fertility rate among the Oraons was higher than the fertility rate in West Bengal (1.80) and India (2.20). Similarly, the under-five mortality rate among them was also higher than the rate in West Bengal (3.20) and India (5.00).[29] It indicates that the group is nowhere near the SDG goals[17] (<25 under-five deaths per 1000 live births).

'Non-literacy' in women was a significant determining factor of fertility and under-five mortality among the Oraons where non-literate women showed a higher chance of high fertility compared to women with primary or secondary level of education. Previously, Moursund et al. and Bongaarts found similar results.[22,30] In the late 90, Caldwell postulated that limited degree to educational exposure cannot alter reproductive norms in indigenous groups.[31] However, Basu (2002) in his review on why education lowers fertility, proposed that in educated women the freedom of decision-making in domestic and reproductive matters and prolonged exposure to education reduces the chance of getting into pregnancy compared to uneducated women.[10] Perhaps in present study group, higher educational exposure of the women have simultaneously reduced their chance of co-habitation and pregnancy.

Regarding under-five mortality, children of non-literate women were at greater risk of experiencing it. This finding validates other pieces of literatures who proposed that parental illiteracy leads to poor knowledge on child-rearing, poor nutritional care and poor access to health care facilities for children which makes them vulnerable to death.[14,32-34]

Study found no effect of occupation of women on their fertility unlike Begall et al.[35] who showed that occupation determined fertility in women. Women from the smaller households in the study group showed lower chance of high fertility similar to the finding of Malakar and Roy (2016) who opined that psycho-social pressure from the family members act as a mediator for pregnancies in women.[13]

The practice of underage (<18 years) marriage in present study group also played a major role in determining fertility and under-five mortality in the study group. It enhanced the chance of high fertility giving women a longer period of exposure for pregnancy.[36] Additionally, underage marriage was found to increase the chance of under-five mortality in present study group. A large cross-sectional study also found that children born to women married below 18 years of age were susceptible to malnutrition and hence exposed to early death.[37]

Under-five mortality was more common to mothers who practised open defecation due to absence of pit latrine in the household. This scenario were consistent with two studies conducted in Nepal and Ethiopia.[7,15] The finding emphasizes that the practice of open defecation may have led to widespread of infections that affected children's health. Nevertheless, association between use of sanitation facilities and under-five mortality was not found by Woldmicael[38] who clearly understood that sanitation practice is a part of complex household aspects and can determine child mortality more prominently with certain other household characteristics like practice of hand-washing, resource of water, etc.

In present study, higher birth order decreased the risk of under-five mortality unlike the findings of Bhandari et al.[19] A further notable result was the absence of sexual preferences on neonatal care in present study findings, since the sex of the child did not influence the risk of under-five mortality. Perhaps, both males and females in adulthood participates in labour force (In some cases, females are preferred) in the tea garden and contribute to household earning.[39] However, Bourne et al.[18] found that neonatal girls in the Indian population were the recipient of less food and treatment than boys which makes them vulnerable to death.

In sum, present study highlighted that education and underage marriage were the responsible factors for both high fertility and high under-five mortality among the Oraon women. The risk of a child's death under five years increased with the open defecation practice of mothers. The study suggests to promote adequate educational exposure and improved sanitary habits in the study population in order to reach the SDG goals. Since the nature of our study was cross-sectional, we limit ourselves to draw any strong conclusion. However, small-scale studies in future with a larger sample size and longitudinal approach may fill the lacuna to get better insights on the present more prominently.

Social Skills Enhancement in Children with Autism– A Way Forward towards Inclusive Society

Angel Selvaraj[1], Sheila Christopher [2]

[1]Assistant Professor, [2]Associate Professor, PG & Research Department of Rehabilitation Science, Holy Cross College, Tiruchirappalli–2

Abstract

Social skills are an important element in developing an individual's personality. Any ailment restricts one's social ability, inhibits relationship with self and others. Social skills pave way in making and having new friends, discovering and developing new skill set from others for personal enhancement. Social skills encompasses skills ranging from play skills, conversation skills, emotional skills, problem solving skills and handling conflicts and decision making skills. This skill is specifically deficient in Children with Autism. Children with Autism may usually appear withdrawn, may appear indifferent to other children and people, the child with (ASD) may prefer to play alone, may approach other children but in an indifferent way. Children with Autism may find it difficult to know how other people may be feeling. Their beliefs, feelings, interests, experiences may be different than that of others. Trying to understand other people may be difficult, exhausting and stressful for children with autism. Many research studies on developing social skills in children with autism have been conducted. This review article has explored research articles which yield solutions to parents and special educators in enhancing social skills in children with autism. The strategies include social skills training, socialization using computer, technology, music therapy, comic strip conversations, applied behavioural therapy (ABA), emotion –based social skills training (EBSST) and visual prompts. Arriving with suitable social skill intervention for these children will aid in successful inclusion of special category within the normal group which in turn will yield our dream inclusive society.

Introduction

Social skills are an important element in developing an individual's personality. Social skills encompasses a range of play skills, conversation skills, emotional skills, problem solving skills and handling conflicts and decision making skills. Social skills pave way in making and having new friends, discovering and developing new skill set from others for personal enhancement. This social skill set is naturally developed by the common population without any major supervision. Children develop these skills by observing and imitating parents, peers and siblings.

The process of Socialization includes managing life tasks, cordial relationship with the community and abiding cultural expectations [(1).] It also involves the regular interaction of biological, socio – cultural and developmental mechanisms [(2)]. Social Competence which emphasize on an impact of individuals behavior in the social situation is a core factor in socialization [(3)]. Few of these specific socialization skills are taught in school and other religious places. Deficit in these social skills in children may guide to more dependency, poor acceptance and Psychological problems.

There is a group of children named Autistic who show considerable difficulties in the areas of social skills.

Autism is a common developmental disability. Autism spectrum disorders (ASD) is characterized by deficits in social communication and social interaction; restricted repetitive patterns of behavior, interests and activities[4]. It is categorized under pervasive developmental disorders as defined in the International Classification of Diseases and Related Health Problems, 10th edition (ICD-10) (WHO 2010) and the Diagnostic and Statistical Manual of Mental Disorders IV, text Revision (DSM-IV-TR) (APA 2000). On focusing on the prevalence of autistic children it is estimated that one in sixty-eight children are diagnosed with an ASD[5], where males are almost five times higher than females.

Though Children with autism are said to have deficits in Communication and socialization, it is commonly found nearly 25 – 70% of children with autism are diagnosed with Poor Intellectual functioning which in turn affects their cognitive and socio-emotional functioning [6]. Among that female children diagnosed with autism are found to have intellectual disability that male children diagnosed with autism [7]. Difficulties in social gaze, joint attention, imitation and speech are commonly found in first year of life of children with autism

Interacting with others in any social occasion, communicating needs/ideas, establishing eye contact, understanding others feelings, interest, emotions are the areas of stress for any child with autism. They appear to be withdrawn and approach others for their need in an unusual way. Children with autism may also react sensitive to certain common sensory stimulus. The above peculiar characteristics of children with autism affects their day to day routine in activities of daily living, education and social life. Thus Autism spectrum disorder not only complicates the life of that particular individual but also the persons associated with them every day.

Autism Spectrum Disorder as a common budding disability has gained the attention of many research scholars and related medical professionals in comprehending their characteristics, its underlying causes and identifying suitable remedial strategies. Though many tailormade strategies are adopted to inculcate specific skills, there are many other concrete research studies on innovative intervention strategies for children with autism.

Upcoming creative training programs, interventions and research studies should yield way to the successful inclusion of children with autism which is an ultimate result of any rehabilitative program. Successful inclusion can be achieved only through two key element ie. Social Integration and Peer Interaction [8].

This review article has explored research studies on interventions which yield solutions to parents and special educators in enhancing social skills in children with autism which in turn results in an inclusive society.

Social Skill Enhancement in Children with Autism

Peer Tutoring: Peer tutoring is a method where students of same age group or friends act as tutors to others. This method is found to be effective in developing social skills among children and adults with Autism Spectrum Disorder.

Training the peers and siblings to assist children with autism to show appropriate social skills through modelling and reinforcement has found an increased social communication in many children and preschoolers with autism and they have also been found to generalize the same over time in other settings thus making peer tutoring an effective model in developing social communication [9,10,11, 12].

Two studies to evaluate the feasibility and efficacy of peer-mediated school-based discrete trial training (DTT) for students with autism spectrum disorder (ASD) was conducted [13]. Results of the study proved that peer-mediated DTT may showed significant progress in both academic skills and inclusion with peers.

A study was conducted to find the effectives of peer mediated Pivotal Response Training with elementary school aged children with autism. The study resulted in increased social skills in children with autism in initiating interactions and turn taking.[14].

Video Modeling: Video Modeling is a visual teaching method where a target behavior or skill is modeled in a video and the learner watch the video and learn the skill through imitation. Video modeling has been found as one of the secure method in enhancing social skills in children with autism.[15,16,17] Video modeling as a best method in teaching and generalizing perspective taking skill in children with autism

A study on teaching social language during play for children with autism using video modeling was conducted and it was found as an effective method in developing social language in children with autism.[18]

Social Stories: Social stories is one of the method where short stories on social situations are formed and children with autism are guided and provided direction in responding to those social situations. These stories are meant to teach social expectations and social behavior. This method was developed by Carol Gray in 1990.

It is found that social stories assist children with autism to prevent maladaptive behavior by providing clear picture and mind map about a social situation, its events and other communicative exchanges [19].

It is found that social stories were effective in developing Initiating conversation skill in children with autism [20].

Various individual studies have proved the efficacy of social stories in developing social skill behavior[21,22], responding to communication [23], recognition of emotion [24], appropriate play behavior[25] and in changing maladaptive behaviors.[26]

Social Skill Training (SST)

Social skill training is a therapeutic intervention in assisting individuals who have problem in relating with others. It is also defined as child centered social or behavioral learning where children are trained in establishing eye contact, initiating conversations and other cooperative skills

SST is found as a suitable method to reduce behavior problems and to promote communication skills in children with autism[27]. Improvement in social skills is observed after SST irrespective of parental involvement and size of the intervention group.[28] Majority of 10 studies has come out with the positive outcome in SST especially in children with high functioning autism.

Though positive review of this training has been documented recommendation are also provided for further research in generalization of skills in social situations outside the therapeutic settings.

Family Based Intervention Models: Historically family based intervention are found to have an impact in the early intervention and rehabilitation of children with autism as they spend most of the time with the family in the early years of development.

Research Evidences has shown young children learn most of their social skills from their family members[29]. They gain most of the learning experience and opportunities in early years of life from the family/ Home Environment.

Parents play a major role in promoting social skills through direct teaching, modeling and by providing opportunities to explore new situations[30]. Siblings presence increased social competence in children with autism due to their proximity with them. Social learning like imitation, expectation of social encounters and regulation of negative emotions are achieved through sibling interaction [31].

Social Skill Enhancement and Inclusion of Children with Autism: Inclusion is meant to provide opportunity to people with disabilities to live a life of their choice irrespective of any information, attitudinal and physical barriers. It also means to respect individual differences rather than ignoring the defects and disabilities. Inclusive education should not intend to replace any of the specialized training and support needs of people with autism. It should rather focus on facilitating early identification and training procedures which will aid in successful mainstreaming of children with autism in the later stage with the normal society. Inclusive society/education should create an ambience where children with autism are provided chances to learn at their best capacity with all accommodative facilities provided.

It is stated that an fully inclusive classroom are perfect location for social and behavioural interventions due to the availability of peers to interact in natural setting. Intervention in regular classrooms has resulted in increased maintenance, generalization and overall success in children with autism. [32]. Apart from regular classroom training regardless of the intervention method early intervention training has proved to more successful.

Studies have also reported children with autism do not get sufficient social skill training and intervention in regular school. This in turn leads to more frustration among the normal peers, regular teachers and children with autism in handling their social skill deficits.

Thus full inclusion of children with autism is possible only when hindrances in regular classrooms are eliminated and alteration in education method, support services are made [33].

Conclusion

In the current scenario education is considered as

an individual's fundamental right irrespective of any disabilities and other restrictions. No two children are same, each one learn in their own style, pace and method. In such circumstances, to provide holistic education in inclusive environment for a child with disability or for children with autism requires an alteration in the existing framework of general education system. Suitable social and behavioral intervention should be made available to children with autism to learn effectively and relate with their normal peers. This requires a great deal of collaborative team work among various professionals. On focusing of social skill enhancement in children with autism no single intervention or management procedure is superior or inferior. Training procedures and interventions are to be tailor-made catering to needs, circumstances, severity of the condition and quality of life of an individual with autism. It is not the setting rather the overall learning environment that determines the successful growth of an individual. A non judgmental environment with supportive family members, competent teachers, acceptable peers and suitable support services can greatly yield to the success of the emerging concept "inclusive society".

Use of Mobile Phone for Academic Purpose among Nursing Students: A Cross Sectional Study

Anju Joseph[1], Deepthi Nair[1], Josmi Jojo[1], Sheheena Majeed[1], Priya Reshma Aranha[2]

[1]II Year PBBSc Students, [2]Assistant Professor, Department of Child Health Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Derlakatte, Mangaluru

Abstract

Background: Technology has influenced the health care education of 21st century. Students depend more on their mobile phones than the books which allows them to access current evidence-based resources. There is a widespread use of mobile phones as reference and information management tools in health care as well as training of healthcare professionals.

Objectives: To know the perception regarding use of mobile phone for academic purpose by nursing students, to identify the pattern of usage and to identify the barriers regarding use of mobile phone as a learning tool.

Materials and Method: It was a cross sectional, questionnaire based study in which pre-designed, pre-tested structured questionnaire were used to collect data. A sample of 125 nursing students from a selected nursing institution were selected using stratified random sampling technique. Data were analyzed using descriptive statistics.

Result: The study results showed that majority (37.6%) of the study participants verbalized that mobile phones could be used for e - learning in nursing education. They were using mobile phone for social networking (80.8%), academic purposes (83.3%), entertainment purposes (82.4%), communication purposes (83.2%). Regarding academic use of mobile phones 85.6% uses for sharing notes and PPT, 58.4% uses for communication about the patients, 78.4% uses for sharing academic schedules, 68% uses to refer study materials, 76.8% uses for studying/learning and 75.2% uses for answering tests and submission of assignments. Majority (99.8%) had a positive perception towards use of mobile phone for academic purpose.

Conclusion: The study concluded that nursing students had a positive perception towards using mobile phone for academic purpose and were using various features of mobile phone for academic purpose.

Keywords: *Mobile phone, Nursing students, Academic purpose Perception, Pattern of usage.*

Introduction

The changing trend of usage of mobile phone for multitasking is increasing day by day among adolescents and adults.[1] Mobile phonehas brought a lot of technological advances to the footstep of mankind. It may be the entertainment, communication, shopping, day to day activities or the educational purpose and so on. Mobile technology is one of the most new technological innovations that can be integrated into medical education. m-learning has been used as a complementary resource for interaction between students and instructors for motivation and learning.[2]

An increasing number of physicians, residents and medical students currently use mobile devices such as smart phones, i Pads and table ts for education and use in clinical environments. The move toward more

learner-centered education facilitates using instructional strategies that engage students in identifying and comprehending key concepts, receiving feedback in the course of the student's learning process and applying concepts to relevant situations. [3]In nursing practice also, the computer literacy has become a survival skill for the profession.[4] Having the support and agreement of the leadership of the hospitals and health institutions, the nurse community is starting to use this technology in many different areas.[5]

A health survey has showed that 65% of nurses are using mobile devices for professional purposes at work at least 30 min per day, while 20% use them for 2 hour or more. 60% use social media to follow healthcare issues at work and 86% follow healthcare issues on social media outside of work. Within the 95% who responded that they access health information at work, 48% of them said that their healthcare institutions encourage nurses to access online resources; 41% allow for occasional use; and 5% only as a last resort. These data suggests that the use of mHealth apps is becoming one of the common activities of the nurses.[6]

A study has reported that mobile app is a promising teaching tool that can be blended with traditional teaching for dental students.[7]The current generation health care professionals feels that mobile phones could increase job efficiency and promote improvement of health care delivery. Mobile phones have become handy tools which assist in learning, interactive instruction, as a self-study education resource or during live formal lectures, laboratory sessions and self- assessments similar to the automated response system[8].

It is observed that nursing professionals also use mobile phones at their workplace. A study has found that 80% of nurse practitioners inclinical practice use smartphone applications (apps) for pharmacology information[9]. In many nursing educational institutions e learning has been introduced and successfully used teaching learning and evaluation and students actively participate in this. It was found that minority andlower-income nursing students are less likely to have internet access at home, but they are likely toown smartphones[10]. Most nursingstudents are adept at the use of mobile phones and find them to be convenient in the clinical setting fordecision-making[11] . The present study was conducted to know the perception of students regarding use of mobile phonein nursing education, identify pattern of usage and to identify barriers regarding use of mobile phone as a learning tool among students.

Materials and Method

It was a Cross-sectional, questionnaire based study conducted at selected nursing institute . Ethical Clearance was obtained from institutional ethics committee and formal permission was obtained from institutional authorities. A questionnaire was prepared by reviewing the literature and got it validated by the subject experts. The questionnaire was pre tested and found reliable (r=0.86). Using stratified random sampling technique, 125 nursing students both under graduate and post graduate, were selected as study participants. All the participating students in this study were explained clearly about the purpose and nature of the study in the language they can understand. They were enrolled in the study only after obtaining a written informed consent. After taking their consent, the data was collected by providing a self-administrated pre-designed questionnaire. The questionnaire consisted of two sections. Demographic proforma and the perception scale. The perception scale consisted of :a) A Likert scale to assess the student's perception regarding use of mobile phone for academic purpose. It was a 5 point Likert scale which has to be rated from strongly agree (5) to strongly disagree (1). The maximum possible score was 90. b) A checklist on use of various features of mobile phones by the students, c)A check list on students use of mobile phone for educational purpose, d) A check list on barriers of mobile use. The collected data was analyzed using descriptive statistics.

Result

The study findings showed that majority (74.4%) of the study participants were using smart phone, majority (76%) own only one mobile phone, majority (36%) were using the mobile phone for 2 to 3 years, majority (51.2%) uses cellular data to access internet in the mobile, majority (25.6%) said that they use internet for other purposes than academic for 1-2 hours, majority (36.8%) says that mobile phone can be probably used as an educational tool, majority (37.6%) said that mobile phones could be probably used for e-learning in nursing education.

It was also seen that majority of the study participants strongly agreed that smart phone are helpful in learning different aspects of nursing (68.8%), smart phones allow students to learn at their own time and place (48.8%), mobile phones promote self directed learning in students (44%), mobile phone usages should be done along with traditional teaching to improve the educational outcomes

(52.8%), smart phones are very useful in clinical for learning unknown technologies, disease condition, treatment modalities etc..(48.8%), smart phones are handy tools for drug dose calculations (48.0%), smart phones can be used to share information's relevant to patient care among the members of health team (45.6%), Smart phone can be used as a guide for reference related to medications literature information's, medical calculations etc. in providing comprehensive care to the clients (49.2%), Use of smart phones may cause some behavioural problem in students (40.0%), Students are at risk for internet addiction (38.4%), Students need guidance towards wise use of smart phone (36.0%). Majority agreed that Smart phone provide a best base for group communication that is useful in effective administration (41.6%), Students using mobile phone may cause financial burden for family (40.8%) and Students of nursing profession should be allowed to use smart phones for academic purpose (44.8%). Majority disagreed that Smart phone reduce the importance of traditional texture and learning from clinical posting (40.8%). Majority strongly disagreed that Smart phones will distract the students from studies (40.0%), Students may find it difficult to control the use of smart phones (42.4%), Smart phones have become a basic need for students and they find difficult to live without it (42.4%).

Table 1: Frequency and percentage of use of various features of mobile phone by the students

Sl. No.	Features	f (%)
1	Call	122(97.6)
2	SMS	113(90.4)
3	Camera	119(95.2)
4	MP3 Player	101(80.8)
5	Movies	114(91.2)
6	Voice recorder	95(76)
7	Video recorder	98(78.4)
8	Multimedia	90(72)
9	Games	89(71.2)

10	Any others -Net work problem, Output problem, Inefficient User Interface (UI), Environmental factor, Battery life is short)	53(42.4)

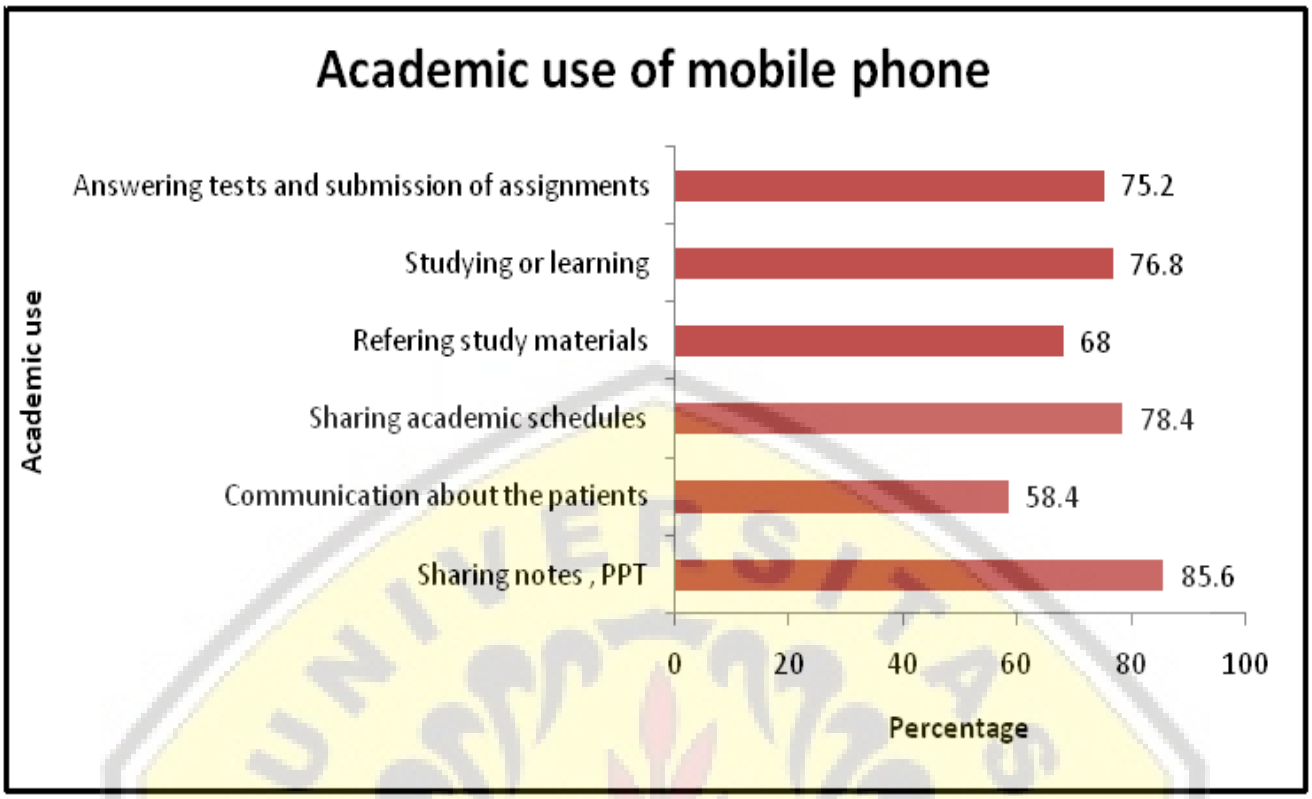

Fig 1: Bar diagram showing the academic use of mobile phone by students

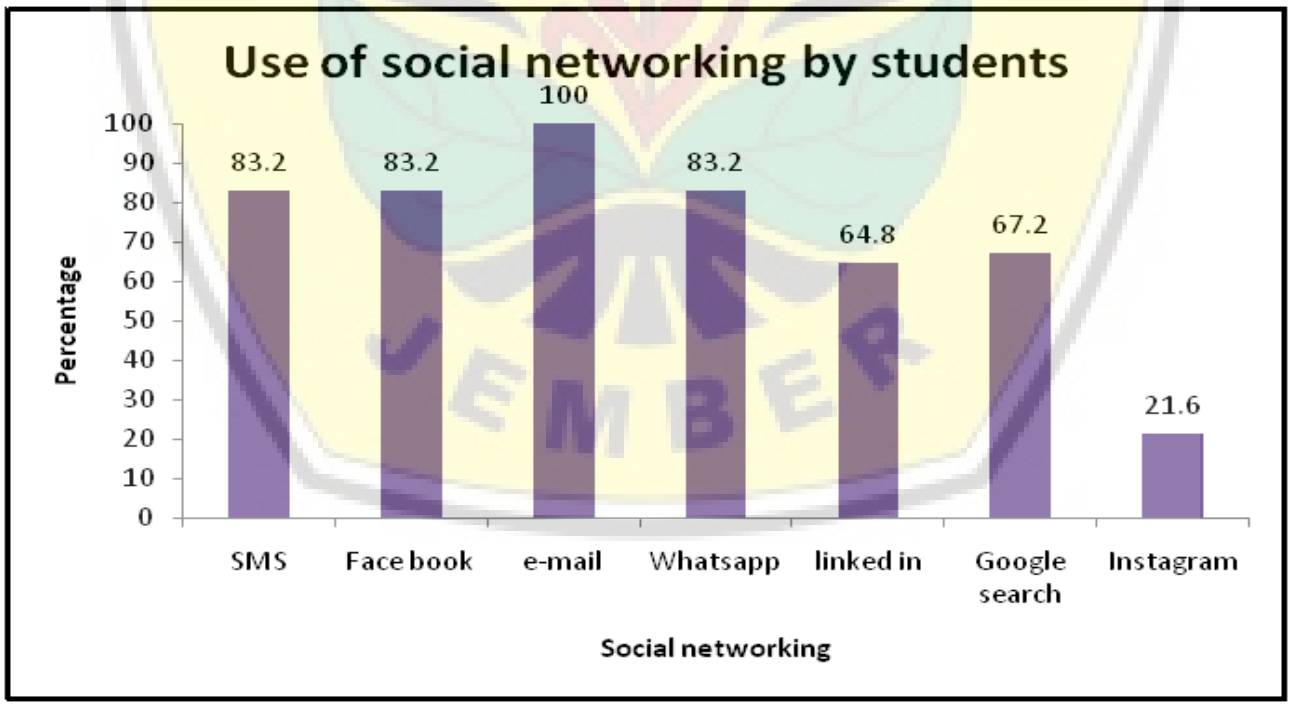

Fig 2: Bar diagram showing the use of social networking by students

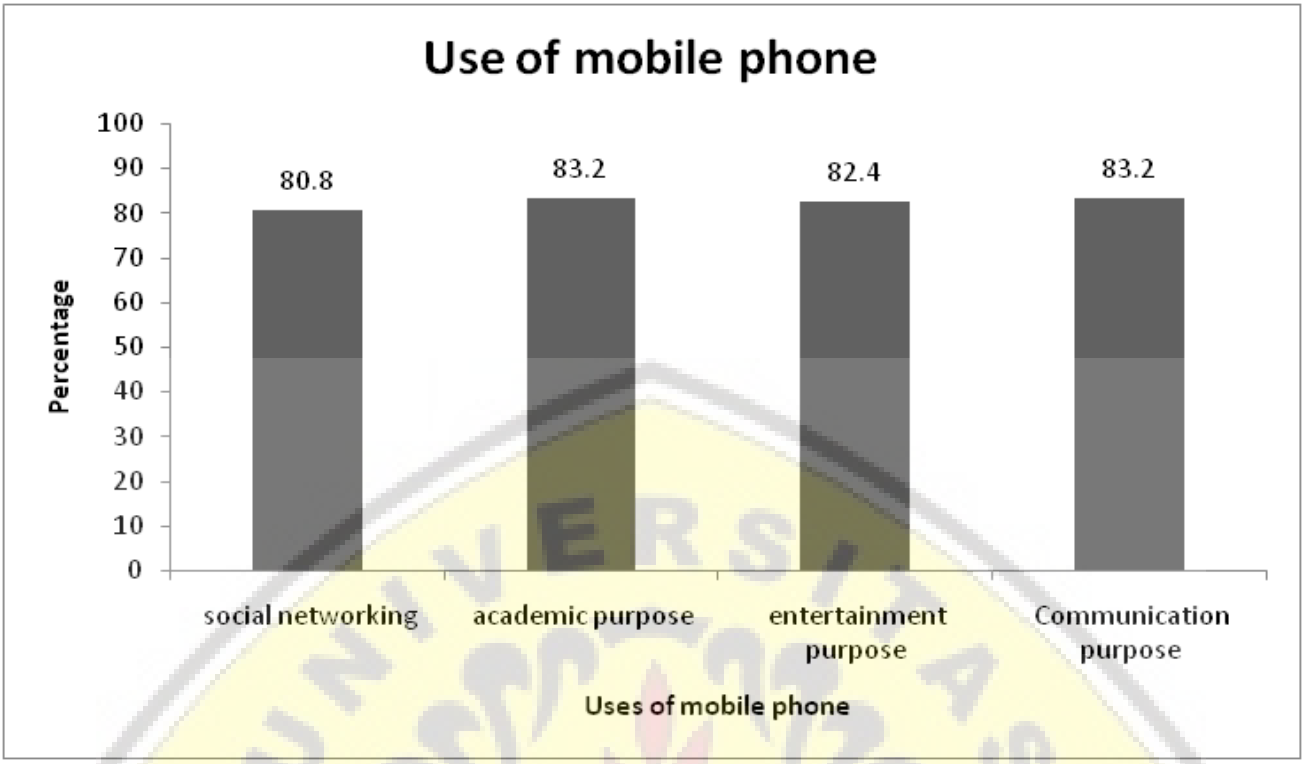

Fig 3: Bar diagram showing the uses of mobile phones for the students

Discussion

With the rapid development of advanced technology, there is an increasing amount of information available in medicine today and use of many portable devices help in quick access to medical information and also plays a major role in quality patient care.[12]

In the current study it is seen that among the study participants majority (74.4%) were using smart phones which is slightly lower than the results shown in a study[13] where the 96.7% students were using smart phones. It was reported in a study[14] that majority of study participants were using iphone, but in the present study Google based android phone is very much commonly utilized. It might because of iPhone are quite costly and cannot afford by students of developing country like India. The use of internet in terms of cellular data or wifi is quite more as seen in a study[13] yet another study reported that students use of internet was less.[15]

. Present study findings showed that majority strongly agreed that mobile phones are helpful in learning different aspects of nursing (68.8%), smart phones allow students to learn at their own time and place (48.8%), mobile phone usages should be done along with traditional teaching to improve the educational outcomes (52.8%), smart phones are very useful in clinical for learning unknown technologies, disease condition, treatment modalities etc.(48.8%). These findings are supported by a study where all the students felt that mobile apps should be used along –with traditional teaching to improve the educational outcomes. However nearly 20% of students showed their concern that apps reduce the importance of traditional lecture and clinical posting.[16]

In the present study majority study participants were using most of the mobile features which is in line with a study finding where majority students were found using the features to call (98%), SMS (74.13%), camera (92.04%), mp3 player (85.82%), voice record (52.74%), video recorder (68,66%), reading (64.52%), multimedia (59.90%), games (61.95%).[17] This study shows that majority of students are using mobile phone for educational purpose,90.4% of them are using dictionaries,72.0% of them using encyclopaedia,76.8% them using for voice recorder, 94.4% of them using for camera. The study result are supported by a study conducted to assess the perception of students regarding feasibility and use of mobile phone dictionaries 43%, encyclopedia 46%, voice recorder 0.7%, camera 43%.[17]

It is seen that the students widely use the mobile phone for academic as well as entertainment purposes. On the other hand, insufficient security, requirement for change, costs, poorly designed packages, inadequate technology, lack of skills, time intensive nature of e-learning, computer anxiety and lack of institutional support are some of the identified barriers [18,19]

The present study was limited to the students using mobile phonein a selected nursing institution in a single geographical area and the students of mobile phone was not observed, only verbal response from the students collected.

Conclusion

Many of the health care institutions have implemented e learning for the students where use of mobile phone plays a important role in their learning process. Sometimes due to ignorance students may misuse the mobile phone and may become addicted to internet or games etc. Therefore it is the responsibilities of the teachers to guide and mentor them regarding the wise use of mobile phones.

The Effectiveness of Reality Orientation Therapy on Cognitive Level of Patient with Dementia at Selected Rehabilitation Center in Pune City

Ms. Anushree Mandal[1], Sheela Upendra[2], Ranjana Chavan[3]

[1]Student of M. Sc. Nursing, [2]Associate Professor, HOD Mental Health Nursing, [3]Assistant Professor (Community Health Nursing), Symbiosis College of Nursing, Symbiosis International (Deemed University), Senapati Bapat Road, Pune Maharashtra India

Abstract

Background and Objective: Dementia, is a group of symptoms associated with a progressive loss of brain functioning. The word "dementia" comes from "de" (without) and "mentia" (mind). Dementia is a syndrome, caused by a variety of brain illnesses that affect memory, thinking, behavior and ability to perform everyday activities. Reality orientation on affective components of mental state, its effect on interpersonal communications and its benefits to formal and informal carers. In some situations, reality orientation can be an effective psychological therapy for people with dementia. Our objective was to assess the effectiveness of Reality Orientation Therapy on Cognitive Level of Patient with Dementia[1].

Research Methodology: Qualitative approach was used. Pre experimental one group Pre-test-post-test research design was used to assess the Effectiveness of Reality Orientation Therapy on Cognitive level of Patient with Dementia at Selected Rehabilitation Centre in Pune City. Cognitive level was assessed with the help of standardized Montreal Cognitive Assessment tool.

40 samples who met the inclusion criteria, by using the non-probability purposive sampling technique. The intervention of Reality Orientation Therapy included the 7 sessions along with various activities in a period of 4 weeks.

Result and Summary: The t_{stat} value for forty sample has been obtained as 1.935. The critical value obtained from t table for a significance level of 0.05 is $t_{cv} = 1.684$. It can be observed that $t_{stat} > t_{cv}$. Hence null hypothesis is rejected & research hypothesis is accepted. Hence it can be concluded that there is a significant difference in the pre-test and post-test MoCA(Montreal Cognitive Assessment) score and the intervention shows effect towards the improvement in the MoCA score which further proves the effectiveness of the intervention of Reality Orientation Therapy.

Religion was found to have significant association with Cognitive level of Patient with Dementia.

Conclusion: The most important part of Patient with Dementia is the declining in Cognitive level. This study suggested that the Reality Orientation Therapy is helpful in improving the Cognitive level of Patient with Dementia.

Introduction

Dementia, is a group of symptoms associated with a progressive loss of brain functioning. The word

"dementia" comes from "de" (without) and "mentia" (mind). Dementia is a syndrome, usually of a chronic or progressive nature, caused by a variety of brain illnesses that affect memory, thinking, behavior and ability to perform everyday activities[1]. Dementia mainly affects older people, although there is growing awareness of cases that start before the age of 65. After age 65, the likelihood of developing dementia roughly doubles every five years. In last year's World Alzheimer Report, Alzheimer's disease International estimated that there are 35.6 million people living with Dementia worldwide in 2010, increasing to 65.7 million by 2030 and 115.4 million by 2050,[2]nearly two-thirds live in low and middle income countries. The stages of dementia are used when a progressive dementia has been diagnosed, it include:

- Stage 1: No impairment. The patient has no problem.
- Stage 2: Questionable impairment. The patient begins to have some difficulty nut can still function independently
- Stage 3: Mild impairment. The patient has obvious, but still mild difficulty with daily activities.
- Stage 4: Moderate impairment. The patient needs help with caring for him or herself as well as with carrying out daily activities.
- Stage 5: Severe impairment; patients are unable to function independently.

Reality Orientation (RO) was first described by Folsom 1966 as a technique to improve the quality of life of confused elderly people, although its origins lie in an attempt to rehabilitate severely disturbed war veterans, not in geriatric work. It operates through the presentation of orientation information (e.g. time, place and person-related) which is thought to provide the person with a greater understanding of their surroundings, possibly resulting in an improved sense of control and self-esteem. RO can be of a continuous 24 hour type, whereby staff orientate the patients to reality at all times, or of a 'classroom' type, where groups of elderly people meet on a regular basis to engage in orientation related activities. A prominent focus of classroom RO is often the 'RO board', which typically displays information such as the day, date, weather, name of next meal and location[3].

Material and Method

A Pre Experimental study design with quantitative approach was used, as this study was aimed, the approach was found to be most appropriate. Experimental group was given intervention of Reality Orientation Therapy (14 different sessions for 4 weeks). This study was conducted in selected Rehabilitation center of Pune city. The selection was based on easy accessibility, cooperation and availability of samples. Total 40 Patients with Dementia of selected Rehabilitation center, Pune city who met the inclusion criteria were selected. Tool used for the collection of data was a standardized tool (Montreal Cognitive Assessment Tool Kit). Findings: The analysis and interpretation of the data collected to determine the Effectiveness of Reality Orientation Therapy on Cognitive Level of Patient with Dementiais carried out based on objectives set by the researcher taking the level of significance as 0.05.

Table No. 1: Effectiveness of Reality Orientation Therapy on Cognitive Level of Patient with Dementia, Pre-test and Post-test comparison n=40

Cognitive Level	Pre-test		Post-test	
	Frequency (n)	Percentage (%)	Frequency (n)	Percentage (%)
Mild (22-25)	14	35	23	57.5
Moderate (17-22)	26	65	17	42.5

Table No. 2: Paired t test for the effectiveness of Reality Orientation Therapy on Cognitive level in Patient with Dementia at Selected Rehabilitation centre in Pune city n=40

	Mean	SD	df (N-1)	p value	t_{stat}
Pre-test	21.300	2.4931	39	0.004	1.935
Post-test	22.150	2.3702			
Difference between two sample	0.85	3.22			

Discussion

Metitiericonducted study to evaluate the impact of continued Reality Orientation Therapy (ROT) in delaying the outcomes of dementia progression. Retrospective study. Data collection was based on review of clinical charts and on telephone interviews performed with patients or primary caregivers. This study analyzed the time to the occurrence of any of the following: cognitive decline on Mini-Mental State Examination scores, urinary incontinence as an index of functional decline, institutionalization and Data on a 30-month period after the first ROT session were analyzed. We compared 46 patients (treatment group) who completed from 2 to 10 ROT cycles (corresponding to 8–40 weeks of training; mean = 15.48) with 28 patients (control group) who completed only one ROT cycle (4 weeks)[4]

In present study done on Cognitive level of mild & moderate Patient with Dementia. Sample size was 40 & intervention (Reality Orientation Therapy) given for four weeks in 7 different sessions. Tool used to assess the cognitive level of Patient with Dementia is MoCA (Montreal Cognitive Assessment). Out of 40 sample in pretest, 35% of Patient with Dementia had mild cognitive impairment and 65% of them had moderate cognitive impairment in pretest. In posttest, 57.5% of Patient with Dementia had mild Cognitive impairment and 42.5% of them had moderate cognitive

Conclusion

The following interpretation can be done from the findings of the study. The analysis of the data reveals that the Effectiveness of Reality Orientation Therapy on Cognitive Level of Patient with Dementia at Selected Rehabilitation Center in Pune city.

Risk Factors on Severity of Blood Pressure among Pregnant Women with Pregnancy Induced Hypertension (PIH) in Hilly areas of Uttarakhand

B. Gomathi[1], Anuchithra S.[2], Ruchira Nautiyal[3]

[1]Associate Professor & Head-OBG Nursing Dept., SUM Nursing College, SOA (DTU) University, Bhubaneswar, [2]Faculty in OBG Nursing, Govt. College of Nursing (SDS TRC RGICD), Bangaluru, Karnataka, [3]Professor and Head-OBG Dept., Himalayan Hospital, SRHU, Dehradun, Uttarakhand

Abstract

Introduction: Pregnancy Induced Hypertension, a life threatening complication of pregnancy is a condition that typically starts after 20th week of pregnancy and is related to increased blood pressure and protein in mother's urine. Finding the factors about increasing the severity of blood pressure among PIH womens is very important to reduce the maternal and newborn morbidity mortality.

Material and Method: Quantitative approach with Non experimental – descriptive research design was used to estimate the risk factors contributing to increase the severity of blood pressure among pregnant women with PIH. Pregnant women who diagnosed with PIH, belongs to hilly area and primigravida were included in the study. Pregnant women with convulsion and coma, with other chronic medical disorders were excluded from the study. Hundred and six (106) women with PIH were selected for study by using purposive sampling technique. Women with PIH were classified in to two groups i.e 1. women with mild BP (140/90 – <160/110) & 2. women with severe BP (≥ 160/110)[2]. The tools used to collect the data were 1. Demographic questionnaire, 2. Questionnaire to assess the determinants or risk factors contributing to increase the severity of Blood pressure of PIH.

Results: Logistic regression Odds ratio statistics revealed that Contraceptive use (β=1.9), underwent infertility treatment (β=1.1), Family history of PIH (β= 2.0), family history of hypertension (β=2.9), physical activity (β=1.2), Sleeping hours (β=1.6), type of diet (β=1.5) and HB level (β=1.2) were the statistically proven causes for worsening of the blood pressure among PIH women.

Conclusion: There are individual and multi-factors (i.e contraceptive use, infertility treatment, family history of PIH, family history of hypertension, normal activity, less sleeping hours, vegetarian and low Hb level)caused to increase the severity of blood pressure among pregnant women with PIH in Hilly Areas.

Keywords: *Blood Pressure, Pregnancy Induced Hypertesnsion, Pregnant women, Risk Factors.*

Introduction

Pregnancy is considered as a normal physiological event and is typically, a time of joy and anticipation. But sometimes occurrence of risk or complications shatters the dreams of pregnant women and her family.[1, 2]

Every minute of every day, somewhere in the world, a woman dies from complications related to pregnancy or childbirth. That is, 3,58,000 women, at a minimum, dying every year worldwide. Most of these deaths occur in developing countries, making maternal mortality the health statistic with the largest disparity between developed and developing countries. In India,

Corresponding Author:
B. Gomathi
Associate Professor & Head – OBG Nursing Dept., SUM Nursing College, SOA (DTU), Bhubaneswar
e-mail: bgomathi84@gmail.com & gomatimahalingam@soa.ac.in

one woman dies in every 5 minutes from a pregnancy related cause.[3]

Hypertension is one of the common medical complications of pregnancy and contributes significantly to maternal and perinatal morbidity and mortality. Hypertension is a sign of an underlying pathology which may be pre-existing or appears for the first time during pregnancy. [2]

PIH, a life threatening complication of pregnancy is a condition that typically starts after 20th week of pregnancy and is related to increased blood pressure (BP ≥140/90 mm Hg) and protein in mother's urine (urinary albumin protein ≥ 300 mg/24 h).[1,2]

Agarwal S, Walia GK (2014) stated the prevalence of PIH in various regions of India and showed that almost one-third of the respondents (n=11362; 28.7%) reported symptoms suggestive of pre-eclampsia. Rural-urban and marked geographic variation were found with rates for pre-eclampsia ranging from as low as 18.5% (Haryana) to 49.4% (Tripura). According to him, Uttarakhand holds the 1st place in the prevalence of PIH in the northern region of India and also it holds 5th place in all over the India.[4]

Till now no study has been conducted to assess the risk factors of severity of blood pressure among PIH mothers in hilly area. Identifying the risk factors contributing to increase the severity of blood pressure among pregnant women with PIH in hilly area will help to screen the high risk cases at booking. It will help the health professionals to plan the suitable surveillance routine to detect preeclampsia for the rest of the pregnancy.

Materials and Method

Quantitative approach with Non experimental–descriptive research design was used to estimate the risk factors contributing to increase the severity of blood pressure among pregnant women with Pregnancy Induced Hypertension (PIH) in hilly area. Pregnant women who diagnosed with Pregnancy Induced Hypertension and registered in respective study centre, belongs to hilly area, primigravida, gestational age between 26 – 30 weeks, willing to give written consent for the study & can understand and speak the Hindi language were included in the study. Pregnant women with convulsion and coma, with other chronic medical disorders were excluded from the study. After taking permission from the ethical committee and administrative authorities. Hundred and six (106) women with PIH were selected for study by using purposive sampling technique. Women with Pregnancy Induced Hypertension were classified in to two groups i.e 1. women with mild BP (140/90 – <160/110) & 2. women with severe BP (≥ 160/110)[2]. The tools used to collect the data were 1. Demographic questionnaire, 2. Questionnaire to assess the determinants or risk factors contributing to increase the severity of Blood pressure of PIH. Informed written consent was taken from each participant before collecting the data. The data analyzed by using descriptive and inferential statistics.

Findings: Frequency & percentage wise distribution of demographic variables of study participants. Highest and almost similar percentages of the women had secondary education (30.2%) & graduate and above (31.1%). Most (88.68%) of the women were housewives whereas, only 11.32% of the women were working. Among 11.32% of the working women, three fourth (75%) of the women were skilled worker and one fourth (25%) of the women were non skilled worker. One third (32.1%) of women belongs to the monthly family income of Rs. 9,249 - 13,873. Two third (65.1%) of the women belongs to the joint family and rural area residence were 70.8%.

Table No. 1: Comparison of risk factors of severity on blood pressure on pregnant women with Pregnancy Induced Hypertension (PIH). N=106

S. No.	Risk Factors	Mild BP (140/90 – <160/110)	Severe BP (≥ 160/110)	Chi Squire	p value	Odds ratio	Confidence Interval	
1	**Maternal age**

Table No. 1 depicts the factors proceeding increasing blood pressure (severity) among pregnancy induced hypertension mothers. Factors like Age of the mother (0.046), Using contraceptives (0.025), Underwent infertility treatment (0.001), Family history of pregnancy induced hypertension (0.0001), Family history hypertension (0.0001), Physical activity (0.005), sleeping hours (0.004), Type of diet (0.035) and Hemoglobin level (0.001) had shown significant ($p \leq 0.05$) association with severity of increased blood pressure among pregnant women with pregnancy induced hypertension. Logistic regression Odds ratio statitics shows that Contraceptive use (β=1.9), underwent infertility treatment (β=1.1), Family history of Pregnancy induced hypertension (β= 2.0), family history of hypertension (β=2.9), physical activity

(β=1.2), Sleeping hours (β=1.6), type of diet (β=1.5) and HB level (β=1.2) were the statistically proven causes for worsening of the blood pressure among pregnancy induced hypertensive mothers.

Discussion

Pregnancy-induced hypertension (PIH) is a state of high blood pressure in a pregnant women after pregnancy and it was reported 7-10% among Indian mothers. This study result shows that Contraceptive use, infertility treatment, family history of PIH, family history of hypertension, physical activity, sleeping hours, type of diet and Hb level were associated in the development severe blood pressure among Pregnancy Induced Hypertensive mothers.

These study findings were consistant with study done by Dalmáz CA, Santos KGD, Botton MR, Roisenberg I that risk factors for hypertensive disorders of pregnancy in Southern Brazilthat family and previous history of PE, high BMI, nulliparity, diabetes, chronic hypertension were reported as a risk factors of hypertensive disorders of pregnancy. Family history of preeclampsia (p = 0.001; OR = 3.88; 95% CI = 1.77-8.46), diabetes (p = 0.021; OR = 3.87; 95% CI = 1.22-12.27) and chronic hypertension (p = 0.002; OR = 7.05; 95% CI = 1.99-24.93) were associated in the development of PIH.[8]

Also, another study done by Agarwal S, Walia GK reported that pre-eclampsia was higher among women with twin pregnancy (OR:1.53; CI:1.12-2.09), terminated pregnancy (OR:1.38; CI:1.30-1.48), women with severe to mild anemia (OR ranges from 1.08 to 1.32), tobacco smoking (OR:1.91; CI:1.19-1.91), diabetes (OR:1.89; CI:1.44-2.49), asthma (OR:2.05; CI:1.59-2.65), consuming fruits weekly/occasionally, eggs daily, fish weekly.[4]

Hirpara S, Ghevariya R, Ghadia P, Hada T, Pandit N mentioned in his study that past history of PIH had strong association with current PIH for women who are multigravida (OR-3.7 95% CI- 1.1 to 12.5 p=0.03). Also there was interesting observation that vegetarian had higher chance of getting PIH then mixed diet pattern (OR-4.3 95% CI- 1.8 to 10.4 p=0.0009). Thus the protein intake has relation. Vegetarian diet population has smaller protein intake compare to mixed type of diet. Other risk factors like family history of hypertension, family history of diabetes mellitus and menstrual cycle history had no association with PIH in present study.[9]

Pandey S, Pandey Ridentified major risk factors in his study were pre pregnancy body mass index (BMI >25) (OR=11.27), history of hypertension (OR=8.65), history of diabetes mellitus (OR=11.0), history of renal disorders (OR=7.98), familial history of hypertension (OR=5.4), history of PIH in earlier pregnancy (OR=9.63) and twin pregnancy (OR=4.85). As per multiple logistic regression analysis the pre-pregnancy BMI of >25 (OR=7.56), history of hypertension (OR=6.69), history of diabetes mellitus (OR=8.66), history of renal disease (OR=5.6), family history of hypertension (OR=5.48) and twin pregnancy (OR=5.73).[10]

Conclusion:

Pregnancy induced hypertension with PE and eclampsia still remain a major problem in developed countries especially in very remote and hilly areas. There are individual and multi-factors (i.e contraceptive use, infertility treatment, family history of PIH, family history of hypertension, normal activity, less sleeping hours, vegetarian and low Hb level)caused to increase the severity of blood pressure among pregnant women with PIH in Hilly Areas. Awareness regarding risk factors for PIH shall be helpful in reducing the PIH related morbidity and mortality. These factors and the symptoms underlying evidence base can be used to assess risk of women belongs to hilly area at booking. High quality antenatal care should be provided in order to minimize the complications of pre-eclampsia both for the mother and the fetus.

Acknowledgement: We would like toacknowledge pregnant women who participated inthis study.

A Study on Socio–Demographical Factors among Granite Industrial Workers of a District in India

Banerji N.[1], Spandana T.[2], Sravan Kumar G.[1], Vijay Kumar U.[3]

[1]MBBS, MD (Community Medicine), Assistant Professor, Dept. of Community Medicine, ASRAM Medical College, Eluru. AP, [2]PG 3 rd Year, Dept. of Pathology, Mamata Medical College, Khammam, Telangana, [3]MBBS, MD (Community Medicine), Professor, Dept. of Community Medicine, ASRAM Medical College, Eluru. AP

Abstract

Background: Preventive medicine and occupational health have same aim–the prevention of disease and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations. Quarrying operations have deleterious effects on both environment and human health.

Aims: To assess the Socio-Demographical factors among workers of granite industry.

Settings & Design: Study Design: Cross-sectional study. Study area: This research was conducted in Khammam town, Khammam. Telangana.

Study Period: 1st December 2015 to 31st November 2016. Study population: Granite industrial workers in Khammam town. Method & Material: Ethical Clearance was obtained from institutional ethical committee and prior permission was sought from the General Manager, District industries centre, Khammam district. The data was collected by Interview technique using validated, semi-structured, pre-tested (pilot tested), proforma developed by the International Union against Tuberculosis & Lung Diseases (IUATLD Questionnaire). Statistical Analysis: It was analysed using SPSS Version 20.0. To test for the difference in the proportion between different variables, Z test/chi-square test was employed. The statistical significance level was fixed at $P < 0.05$. Results: A total of 402 granite workers from the age group of 23 to 57 years participated in the study, of them 290 (72.1%) were males and 112(27.9%) were females. Majority of the workers i.e. 258 (64.2%) belonged to Class III Socio-economic status. Among the total workers, 128 (31.8%) of them were smokers. Conclusion: There is a need to evaluate the health status of quarry workers at regular intervals to provide appropriate preventive measures.

Keywords: *Granite industry workers, smoking, Alcohol, quarrying, socio-demographical.*

Introduction

India with its diverse work has 90% of the workforce belonging to informal sector where the work and working conditions are variable and insecure in nature. This coupled with poverty has pushed them to take up hazardous and precarious employment in the informal economy. For these workers, any employment is acceptable as long as it meets their hunger and poverty. Just like home, the place of work is also an important environment for an earning person. Such a person spends nearly 6 – 8 hours a day [1]. Added to this, extended working hours, labor exploitation, poor wages coupled with employer's apathy towards Health & Safety of these workers, adds to the Occupational hazards and risks at workplaces. Lack of implementation of Health & Safety legislation among unorganized sector is another challenge to be addressed[2]. Preventive medicine and

occupational health have same aim – the prevention of disease and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations[3]. Quarrying being one such informal sector constitutes 8% of the unorganized sector[4]. Quarrying operations have deleterious effects on both environment and human health. National Institute for Occupational Safety and Health (NIOSH) reports dusts generated from granite quarrying contains 71 percent silica[5].

Despite the above said health impacts of quarrying on health especially on respiratory system, Many studies have focused on Sandstone quarrying. Hence was the need for designing and carrying out this study.

Aim and Objective: To assess the Socio-Demographical factors among workers of granite industry.

Material and Method

Study Design: Cross-sectional study

Study Area: This research was conducted in Khammam town, Khammam. Telangana.

Study Period: 1st December 2015 to 31st November 2016.

Study population: Granite industrial workers in Khammam town.

Inclusion Criteria: All the individuals working in granite factories of Khammam town were included in the study.

Exclusion Criteria: Individuals not willing to participate in the study.

Sample Size Estimation: Sample size was calculated by taking Confidence interval (CI) at: 95%

Alpha error (α): 5%

Allowable error (L): 20% of p

Assumed prevalence (P): 20%

The basis for the estimation of sample size for the present study was Comparison of respiratory morbidity between present and ex-workers of quartz crushing units: Healthy workers' effect by Tiwari RR et.al [6])

Sample Size Calculation (n): $4PQ/L^2 = 4 X 20 X 80/(4 X 4) = 400$

Sample size for our study was 400.

Method of Data Collection: Ethical Clearance was obtained from institutional ethical committee and prior permission was sought from the General Manager, District industries center, Khammam district before the commencement of the study. After acquiring approval letter from the District Labour Officer, Khammam, Preliminary enquiries as to number of granite factories in the town, names of the factories, its owners and members who were working in granite quarries were made and Individuals took part in the study voluntarily and were permitted by their employer from their unit for the evaluation. We visited different study sites, discussed the intention of the study with the individuals. The purpose of the study was explained to the owners and all the workers and their consent was taken in this regard. The data was collected by Interview technique using validated, semi-structured, pre-tested (pilot tested), proforma developed by the International Union against Tuberculosis & Lung Diseases (IUATLD Questionnaire) [7]. It included Socio-demographic details on age, sex, educational status, marital status, socio-economic status and duration of present stay in the residence. Known confounding variables that were considered in the study included history of smoking, consumption of smokeless tobacco and alcohol.

Statistical Method: The data was entered onto a computerized Excel (Microsoft Excel 2010) spreadsheet. Subsequently it was analyzed using SPSS (Statistical Package for Social Sciences) Version 20.0 Data were tabulated according to frequency distribution tables . Quantitative Variables such as age, duration of working etc. were summarized through mean, median etc. To understand the variation in the data, SD was calculated. To test for the difference in the proportion between different variables, Z test/chi-square test was employed. The statistical significance level was fixed at $P < 0.05$.

Observations and Results

A total of 402 granite workers from the age group of 23 to 57 years participated in the study. Majority of the individual in the study consisted of males 290 (72.1%) and only 112(27.9%) constituted females.

It was observed that 360 (89.6%) of the granite workers were married at the time of interview. This distribution was followed by widow/er individuals, constituting 41(10.2%) granite workers.

Table 1: Age distribution of the study population

Age (Years)	Males n = 290	Females n = 112	Total n = 402
20 – 29	42(14.5%)	19(17.0%)	61(15.1%)
30 – 39	110(38.0%)	51(45.5%)	161(40.0%)
40 – 49	102(35.0%)	39(34.8%)	141(35.1%)
50 – 59	36(12.5%)	3(2.7%)	39(9.8%)
Total	290(100.0%)	112(100.0%)	402(100.0%)

Note: Figures in parenthesis indicates column percentages

Figure 1: Distribution of study population according to educational status

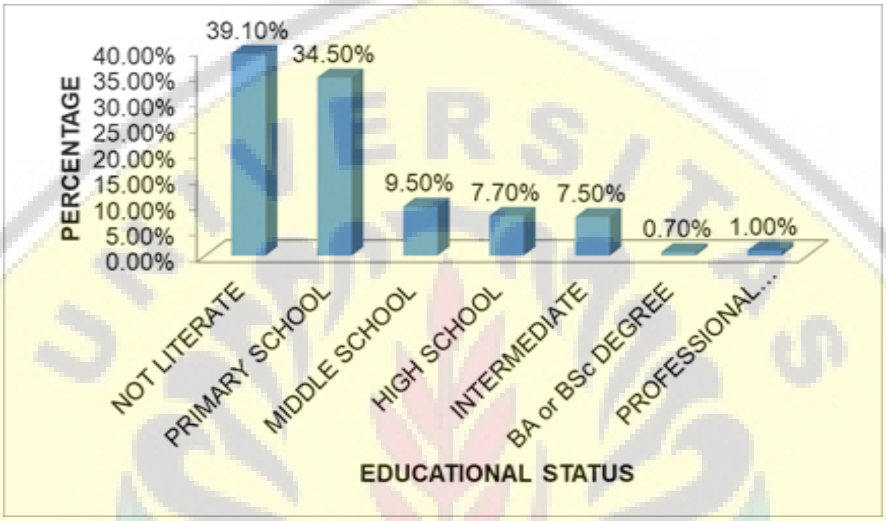

Figure 2: Distribution of study population according to socio economic status (According to Modified B G Prasad's classification)

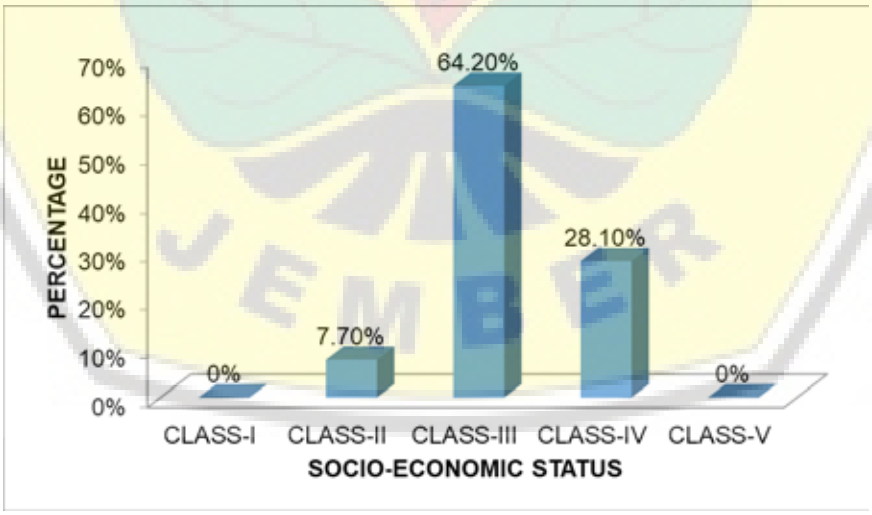

Table 2: Distribution of Study population according to history of Smoking

Smoking History	Males n = 290	Females n = 112	Total n = 402
Smokers	124(42.8%)	4(3.6%)	128(31.8%)
Non-Smokers	166(57.2%)	108(96.4%)	274(68.2%)
Total	290(100%)	112(100%)	402(100%)

X^2= 57.170, df = 1, P = 0.00001 ($p < 0.05$)

The association between smoking and gender was found to be statistically significant (P< 0.05) as shown in Table 2.

Table 3: Distribution of Study Population by consumption of smokeless tobacco

Smokeless Tobacco Consumption	Males n = 290	Females n = 112	Total n = 402
Consumed	119(41.0%)	16(14.3%)	135(33.6%)
Did not consume	171(59.0%)	96(85.7%)	267(66.4%)
Total	290(100%)	112(100%)	402(100%)

X^2= 25.918, df = 1, P = 0.00001 (p < 0.05)

Thus, a higher consumption of smokeless tobacco was prevalent among male workers as compared to female workers and this association was found to be statistically Significant (P< 0.05) as shown in Table 3.

Table 4: Distribution of the Study population according to consumption of alcohol

Alcohol Consumption	Males n = 290	Females n = 112	Total n = 402
Consumed	225(77.6%)	8(7.2%)	233(58.0%)
Did Not Consume	65(22.4%)	104(92.8%)	169(42.0%)
Total	290(100.0%)	112(100.0%)	402(100%)

X^2 = 164.54, df = 1, P = 0.00001 (p <0.05)

The association between alcohol consumption and gender was found to be statistically significant (P<0.05) (Table 4).

Discussion

A total of 402 granite workers from the age group of 23 to 57 years participated in the study, of them 290 (72.1%) were males and 112(27.9%) were females (Table 1). Considering the strenuous nature of the job, not many female individuals were employed in the field and most of the employed female's job restricted to labour job and not into crushing and polishing process. A study by Tiwari et al [6] in Godhara among 253 quartz stone workers and 102 slate pencil workers found 191 (75.5%) males and 62 (24.5%) females among the study group. A study done by Manish A Prasad et. Al [8], to assess health status of stone quarry workers in Wardha district, Central India, found that 138 (92%) workers were males and 12 (8%) were females. Among the study population, 302 (75.1%) individuals were in the age group of 30 to 49 years followed by 61 (15.1%) between 20 to 29 years and 39 (9.8%) in the age group of 50 to 59 yrs. Hence, majority of the study population comprised of middle aged individuals aged less than 50 years. And Mean ± SD age of the study population to be 38.06 ± 7.77 years. Another cross sectional study by Tiwari et al carried out among 136 quartz stone grinders with the objective to study the peak expiratory flow (PEF) and the epidemiological factors associated with it found that the mean age for male was 33.18 ± 10.39 years while that for female was 30.10 ± 9.3 years and for the whole group was 31.77 ± 9.99 years [9]. Present study revealed that 360 (89.6%) of the granite workers were married at the time of interview. This distribution was followed by widow/er individuals, constituting 41(10.2%) granite workers (Table 3). A cross- sectional study done by Narkhede V et.al [10] with objective of respiratory morbidity among stone crusher workers found that 243 (84.67%) workers were married followed by 44 (15.33%) unmarried workers. A study done by A. N. Nwibo, E. I. Ugwuja et al [11] in which majority of workers are married with a percentage of 58.3% and 41.7% workers were unmarried. Education is considered as an important factor for empowerment of the work force to appreciate ones rights and to protect themselves from the hazards in the industry. This concurs with the fact that the most vulnerable individuals are the ones who are least equipped with the knowledge and skills to protect themselves from the hazards and constitute the target groups for focused interventions while promoting occupational health and safety as owing to their lack of education, most workers in the "developing" world are unaware of the hazards of their occupations. Majority of the workers i.e. 258 (64.2%) belonged to Class III

Socio-economic status, 113(28.1%) workers belonged to class-IV Socio-economic status. Since most quarry workers belonged to lower middle and upper middle socioeconomic class, their affordability and accessibility to quality occupational health services both in the private and public health sectors may be variable and may be compromised. This justifies the need to organize and deliver comprehensive occupational health services within and allied health systems. Vilanilam et al [12], in their paper on historical and socioeconomic analysis of occupational safety and health in India, highlight the fact that low socio-economic status of the workers, contributes a great deal to their general backwardness in sanitation and nutrition that often aggravate diseases contracted from the work environment. Among the total workers, 128 (31.8%) of them were smokers, 274 (68.2%) were non-smokers. Tiwari et al showed that among the 253 quartz stone workers, 38.7% were smokers and 61.3% were nonsmokers [9]. Surveys in India have revealed that 29.4% of males and 2.5% of females are current smokers. However, in those 30 years of age and above, the prevalence of smoking in India is 40.9% for males and 3.9% for females [13]. The present study showed that, 135 (33.6%) were chewing one or other form of smokeless tobacco. A study done by Manish A Prasad et. Al [8] to assess health status of stone quarry workers in Wardha district, Central India, found that 78 (52%) workers were chewing smokeless tobacco in the form of pan masala and gutkha. Among the workers, 233(58.0%) consumed alcohol and 169(142.0%) did not consume. The difference on the alcohol consumption between males and females was found to be statistically significant ($P<0.05$) (Table 8). The probable reason for high consumption of alcohol among the male workers could be referable to the type of work they are engaged into. Male workers are involved in strenuous job for a period of 8 hours a day and most of the months in a year. So in order to relax in between their working hours, they could be consuming more amount of alcohol. The same could be explained for high consumption of tobacco among them as compared to female workers.

A study done by Manish A Prasad et. Al [8] to assess health status of stone quarry workers in Wardha district, Central India, found that only 4 (2.77%) workers were consuming alcohol.

Conclusion

The present research has also revealed that continuing the occupation of quarrying for ≥ 10 years may add to the development of several respiratory morbidities namely hemoptysis, bronchial asthma, atopy and chronic bronchitis which will in turn have deleterious effect on the health status of the population more so with respiratory morbidity.

There is a need to evaluate the health status of quarry workers at regular intervals to provide appropriate preventive measures.

Assessment of Bowel Habits among Selected Community Adult Population

Bavithra Devi K.[1], Ramya V.[1], Kowsalya C.[3], Karthiga A.[1], Rathiga A.[2]

[1]B.Sc. (N) IV[th] Year Student, Chettinad College of Nursing, Chettinad Academy of Research and Education, Tamil Nadu, India, [2]Vice Principal, Chettinad College of Nursing Chettinad Academy of Research and Education, Tamil Nadu, India

Abstract

Background: Defining bowel habit it's an important human body function. Stool frequency and consistency normally change person to person. Bowel habits are formed early in life. So they may have poor habits and developing the problems. Many people don't know that they have poor bowel habits or problems. Without treatment, these could lead to faecal incontinence (leakage from the bowel) in later life.

Objectives: To assess the bowel habits (Characteristics, Pattern and Control) among adult population and to find the association with selected demographic variables. Material and Method; a descriptive study to assess the bowel habits among adult among population. The non probability, Convenient sampling technique was followed and 106 adult in selected community who met inclusion criteria were selected Standardized Victoria Bowel Performance Scale were used to assess the bowel habits among adult population. The collected data were formulated and analyzed by using descriptive and inferential statistics.

Result: Shows, that majority of adult 45.28% were in the age group of 30 - 39, 66.03% were in female, 42.22% had primary education, 98.11% got married, 52.83% had unemployed, 95.28% have been taken fibre rich diet, 45.28% were spending the time of exercise 15 to 30 minutes, 60.37% taken water in evening time, 90.56% does not having smoking and 88.67% does not drinking alcohol and there is no significant association between the bowel habits with selected demographic variables Hence, the null hypothesis is accepted.

Keywords: *Assessment, Bowel habit, Adult.*

Introduction

Defining normal bowel habit is important when evaluating diarrhea or constipation. Normal stool frequency and consistency vary from person to person and in different populations due to several factors including dietary habit, quantity of fiber intake and difference in gut transit time Misconception regarding bowel habit is common among general population.

Define constipation according to stool frequency patients define this problem as a multi-symptom disorder such as infrequent bowel movements, hard/lumpy stool, straining, bloating and feeling of incomplete evacuation a bowel movement and abdominal discomfort. Constipation has multitude of causes with higher prevalence among females, older age group, low education and economic group. Therefore, it is not surprising that they represent one of the least understood aspects of human behavior. In the past, most knowledge of bowel habits was drawn from limited data on small groups of subjects (nurses, jail prisoners, elderly people

Corresponding Author:
Ms. Bavithra Devi K.

and students). More recently, studies aimed generically at investigating functional gastrointestinal disorders have large number of people.(1)

Defecation is a basic body function that affects the quality of life. Dietary intake and gastrointestinal motility functions are important in critically-illpatients. However, scant attention has been given to motility disorders of lower gastrointestinal tract and problems of failure to defecate in critically ill patients. Constipation is a common complaint among critically ill patients. Poor dietary and fluid intake, impaired mobility leads to decreased muscle tone and decreased peristalsis, thus, contributing to development of constipation. Hospitalized critically-ill patients receiving opioids, sedatives, anticonvulsants and many others drugs are more likely to develop lower gastrointestinal motility disorders. However, a study revealed that motility disorder is common problem among persons receiving sedatives. (2)

Defining normal bowel habit is important when evaluating diarrhea or constipation. Normal stool frequency and consistency vary from person to person and in different populations due to several factors including dietary habit, quantity of fiber intake and difference in gut transit time. Studies showed that 98% normal persons had bowel movement ranging between three stools per day and three per week and Some degree of urgency, straining and incomplete evacuation should be considered normal.(3)

Constipation is a major public health issue because of its high prevalence, economic cost and adverse effects on quality of life and health status. It is not a specific disease but a general term that describes a wide range of symptoms associated with straining, hard stools, incomplete evacuation, anorectal obstruction, manual maneuvers or infrequent stools.(4)

Constipation affects multiple aspects of a person's health, including health-related quality of life. It is one of the most frequently reported functional gastrointestinal disorders. The purpose of this integrative review of the literature was to identify research findings pertaining to the prevalence of constipation and factors are associated with constipation in the general population. (5)

Method and Material

A descriptive study was conducted to assessment of bowel habits among selected in community adult population selected Kanchipuram District, Tamil Nadu, India. A quantitative research approach was considered appropriate for the study. Research design selected present study was descriptive cross sectional design. The population of the present study include demographic variable aged 30 to 60 years .the researcher obtained ethical clearance from IHFC and permission from concern authority. The study conducted in pooncheri and paiyanur village the people cooperation for the study. The 106 sample were selected through non probability convenient sampling technique as per the sampling criteria. The necessary data collected from the record in the present study research tool demographic variable like defecation, constipation and diarrohea it's also developed vectoria bowel tool. The data collection was done. Tabulated and analyzed in term of objective of the study byusing descriptive and inferential statistics.

Result

The result shows that majority of adult 45.28% were in the age group of 30 - 39, 66.03% were in female, 42.22% had primary education, 98.11% got married, 52.83% had unemployed, 95.28% have been taken fibre rich diet, 45.28% were spending the time of exercise 15 to 30 minutes, 60.37% taken water in evening time, 90.56% does not having smoking and 88.67% does not drinking alcohol and there is no significant association between the bowel habits with selected demographic variables Hence, the null hypothesis is accepted.

Table 1: Frequency Percentage distribution of assessment of bowel habits among adult population N=106

S.No	Variable	Constipation		Normal		Diarrhea	
		No.	%	No.	%	No.	%
1	Characteristics	15	14.15	86	81.13	5	4.71
2	Pattern	10	9.43	92	86.79	4	3.77
3	Control	15	14.15	88	83.01	3	2.83

The Table 1 shows regarding Characteristics 15% of people had constipation, regarding pattern 10% of people had constipation and regarding 15% of people had constipation.

Conclusion

The study result show majority of adult bowel habits normal 81.4%, constipation 14.15% and diarrohea 4.71%. The purpose of this study was used to assess the bowel habits among adult population. From the above findings shows the adult had constipation, normal and diarrrhea. On the whole, carrying out of the present study was really an enriching experience to the investigator. It also helped a great deal to explore and improve the health.

To Assess the Perceived Factors Influencing Work Place Violence among Nurses in Selected Hospitals, Mangaluru: A Descriptive Study

Bhagya[1], Divya Dsouza[1], Josna Jose [1], Saritha Dsouza[1], Syed Imran[2]

[1]PB. B.Sc. Nursing Student, [2]Associate Professor Mental Health Nursing Department, Yenepoya Nursing College, Yenepoya University Deralakatte Mangaluru

Abstract

Background: Work place violence has become an endemic problem for health care worker (HCW) worldwide. The staff nurses are the most vulnerable. The study conducted with the aim to assess the frequency of violence and perceived factors responsible for violence.[6]

Objective: To assess the perceived factors influencing work place violence among nurses. To find out association between the perceived factors influence work place violence and demographical variables.

Materials and Method: It was descriptive study, questionnaire based in which test re-test self administered rating scale used to collect data. A sample of 100 staff nurses from selected hospitals. Non-probability purposive sampling technique used . Data analyzed using inferential statistics.

Result: The study revealed that Majority 91(91%) of staff nurse belongs to 21 – 30 years, subject 82 (82%) females, 78 (78%) staff nurses working in the ward, 45 (45%) staff nurses below 2 years, 61 (61%) GNM, staff nurses 77 (77%) nuclear family, 84 (84%) designation of the staff nurses, 80 (80%) staff nurses single, 93(93%) staff nurses reported their interaction with others during work shifts, staff nurses 86(86%) had direct physical contact (washing, turning, lifting) with the patient, 59 (59%) of them worked with female patient and 50(50%) of them worked with 3-4 staff nurses.

The study shows that majority (48.8%) of the staff nurses agree that social factors are influencing work place violence whereas, (6.2%) strongly disagrees. Most of the (43.36%) staff nurses believe job related factors influencing the work place violence and (6%) states that not influencing. Majority (44.2%) of the staff nurses agree that psychological factors influence work place violence whereas, (6.4%) states not influencing . The staff nurses (45%) reports educational factors influencing the work place violence and (5.8%) strongly disagree. Majority (46%) of the nurses agree that economic factors are influencing work place violence whereas, (7%) staff nurses disagree.

Conclusion: The finding of the study most of the perceived factors associated with work place violence.

Introduction

The work place violence is an aggressive behaviour aimed at harming the people. Workplace violence is defined as an incident where staff members are abused and threatened at their workplace. Workplace violence is regarded as a problematic and significant issue for the nursing profession worldwide [1].

There are main five perceived factors which influencing work place violence such as social factors; those are religion, life style culture. Educational factors are illiterate, literate, knowledge. Job related factors skill, experience and work ability. Psychological factors stress, emotions and other factors family, communication and economic status.

Materials and Method

It was a descriptive study, self administered rating scale based study conducted in selected hospitals . Ethical Clearance was obtained from institutional ethics committee and formal permission was obtained from institutional authorities. A questionnaire was prepared by reviewing the literature and got it validated by the subject experts. The questionnaire test re-test found reliable (r=0.86). Using non- probability purposive sampling technique, 100 nursing staffs, were selected as study participants. All the participating nursing staffs in this study were explained clearly about the purpose and nature of the study in the language they can understand. They were enrolled in the study only after obtaining a written informed consent. After taking their consent, the data was collected by providing a self-administrated structured questionnaire. The questionnaire consisted of two sections. Demographic proforma and the rating scale. The rating scale consisted of to assess the perceived factors influencing work place violence among staff nurses . It was a 4 point scale which has to be rated from strongly agree (4) to strongly disagree (1). The maximum possible score was 120.

Result

The study findings showed majority (91%) of staff nurses belongs to 21-30 years, majority of subject (82%) were females, majority (78%) staff nurses were working in the ward, majority (45%) staff nurses were below 2 years, majority (61%) GNM, majority staff nurses were (77%) nuclear family, majority (84%) were designation of the staff nurses, majority (80%) staff nurses were single, majority (93%) of the staff nurses reported their interaction with others during work shifts, majority of staff nurses (86%) had direct physical contact (washing, turning, lifting) with the patient, (59%) of them worked with female patient and (50%) of them worked with 3-4 staff nurses.

The study shows that majority (48.8%) of the staff nurses agree that social factors are influencing work place violence whereas, (6.2%) strongly disagrees about social factors influence on work place violence. Most of the (43.36%) staff nurses believe job related factors influencing the work place violence and (6%) states that job related factors are not influencing for work place violence. Majority (44.2%) of the staff nurses agree that psychological factors influence work place violence whereas, (6.4%) states psychological factors are not influencing work place violence. The staff nurses (45%) reports educational factors influencing the work place violence and (5.8%) strongly disagree that the educational factors influence the work place violence. Majority (46%) of the nurses agree that economic factors are influencing work place violence whereas, (7%) staff nurses disagree with economic factors influencing work place violence.

Bar diagram shows perceived factors work place violence:

Table No. 1: Area wise perceived factors influencing work place violence

Sl.No.	Factors	Strongly Agree	Agree	Disagree	Strongly Disagree
1.	Social factors	26%	48.8%	19%	6.2%
2.	Job related factors	30.18%	43.36%	20.45%	6%
3.	Psychological factors	28%	44.2%	21.4%	6.4%
4.	Educational factors	26%	45%	23.2%	5.8%
5.	Economical factors	30.5%	46%	16.5%	7%

Discussion

In this chapter finding of the study has been discussed with reference to objectives and in relation with the findings of the previous study.

This chapter deals with the discussion of the study with appropriate literature review. Statistical analysis and findings of the study based on objective of the study. The aim of the present study was to assess the perceived factor influencing work place violence among the staff nurses in Yenepoya Medical College hospital Mangaluru. The total of 100 staff nurses from Yenepoya Medical College Hospital Mangaluru. Were selected for the study by Non probability purposive sampling method. The findings are discussed under the demographic characteristics and objectives.

- To Assess the perceived factors influencing work place violence among the nurses.
- To find out Association between the perceived factors influence work place violence and selected demographical variable.

The following study is discussed under the following parts.

Section 1: Demographic variables of staff nurses

Section 2: Perceived factors influencing work place violence

Section 3: Association between the perceived factors and demographic variable.

Section 1: Demographic variables of staff nurses: Majority 91(91%) of staff nurse belongs to 21 – 30 years, Majority subject 82 (82%) were females, Majority 78 (78%) staff nurses are working in the ward, majority 45 (45%) staff nurses are below 2 years, majority 61 (61%) GNM, majority staff nurses are 77 (77%) are nuclear family, majority 84 (84%) are designation of the staff nurses, majority 80 (80%) staff nurses are single, majority 93(93%) of the staff nurses reported their interaction with others during work shifts, majority of staff nurses 86(86%) had direct physical contact (washing, turning, lifting) with the patient, 59 (59%) of them worked with female patient and 50(50%) of them worked with 3- 4 staff nurses.

Similar findings were also found in a study where (50%) of participant were married and less than 2% were divorced or widowed. Most participants (80%) were employed by the government. [14]

Comparable results were also seen in a study where (75%) of the nurses of age group 36-40 years were found to be more exposed to work place violence. The separated/divorced (0.5%) and single (45%) nurses were found more exposed to work place violence than married nurses. The nurses less than 10 years of experience (65.1%) hand experienced more work place violence. Part time nurses (80%) were exposed to work place violence. The majority of the nurses who worked at the time of 6pm to 7 am (75%) and in the intensive care unit (84.6%) hand experienced more work place violence.[1]

Section 2: Perceived factors influencing work place violence: The study revealed that majority (48.8%) of the staff nurses agree that social factors are influencing work place violence whereas, (6.2%) strongly disagrees about social factors influence on work place violence. Most of the (43.36%) staff nurses believe job related factors influencing the work place violence and (6%) states that job related factors are not influencing for work place violence. Majority (44.2%) of the staff nurses agree that psychological factors influence work place violence whereas, (6.4%) states psychological factors are not influencing work place violence. The staff nurses (45%) reports educational factors influencing the work place violence and (5.8%) strongly disagree that the educational factors influence the work place violence. Majority (46%) of the nurses agree that economic factors are influencing work place violence whereas, (7%) staff nurses disagree with economic factors influencing work place violence.

In the study work place was reported 59.7% of health care workers. Verbal violence was the most reported (58.2%), compare to physical violence (15.7%), the most report reason for violence were waiting time and that patient and family expectations not met. Only (29%) of health care workers who experienced verbal violence and (23.8%) of experienced physical violence reported it to hospital authority about (75%) of health care workers through that work place violence could be prevented.[16]

Section 3: Association between the perceived factors and demographic variable: Association between the perceived factors and demographic variable that is age (χ^2=.079, P=0.05), gender (χ^2=.826, P=0.05), area of work (χ^2=.026, P=0.05) working experience (χ^2=.924, P=0.05), education qualification (χ^2=.175, P=0.05), type of family (χ^2=.540, P=0.05), designation

(χ^2=.536, P=0.05), marital status (χ^2=.032, P=0.05), do you interact with any one during your work place (χ^2=.598, P=0.05), do you have direct physical contact (washing, running, lifting) with patient (χ^2=.424 P=0.05), the gender of patient you most frequently work with are (χ^2=.026, P=0.05), the number of staff present in the same work setting with you during most of your work time is (χ^2=.603, P =0.05).

A study conducted among physician and nurses on violence exposure among healthcare professionals public hospitals of capital city of Riyadh in Saudi Arabia, reported that nurses were more that nurses were more predisposed to the acts of violence as compared to their doctor colleagues. Verbal abuse was total noted to be the most frequently occurring act of violence and the reason cited for the same were the unmet needs of patients along with long waiting hours. This study found the relatives to be the most common perpetrators. [20]

Summary: The chapter deals with the major findings and discussion of study in the light of the review of literature. There are some studies from review of literature that has supported to this study. Other studies reveals that they had been factors influencing work place violence.

Conclusion

The work place violence are more commonly happens in health care settings. The preventions of work place violence is necessary. The prevention of violence is not easy.

A Comparitive Study to Assess the Level of Distress Among Patients with Cancer Undergoing Chemotherapy and Radiation Therapy in Selected Oncology Centers Mangaluru

Catty Katherine Jose [1], Christina John[1], Claramma Jacob[1], Cleena Gonsalves[1], Dayana Thomas[1], Deena John[1], Syed Imran[2]

[1]IV[th] Year B.Sc. Nursing Students, [2]Associate Professor, Department of Mental Health Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be) University, Derlakkatte, Mangaluru, Karnataka, India

Abstract

Objectives: To determine the level of distress among patients with cancer undergoing radiation therapy, to determine the level of distress among patients with cancer undergoing chemotherapy, to compare the level of distress among patients undergoing radiation therapy and chemotherapy, to determine the association between the level of distress and selected demographic variables.

Method: The research design selected for the study was a descriptive survey design. In the present study, the sample consisted of 100 cancer patients who were selected based on the inclusion criteria.

Result: The mean percentage of distress was 50% of both chemotherapy and radiation therapy or there is equal distress in both groups (chemotherapy and radiation therapy) irrespective of treatment, cancer patients have distress. so there is no significant association was found between distress score with demographic variables.

Conclusion: The overall findings of the study revealed that distress is common for all cancer patients and the treatment modalities (chemotherapy and radiation therapy) have no relation with the distress.

Keywords: *Distress, cancer, chemotherapy, radiation therapy.*

Introduction

Cancer is the second most cause of death in the developed world and similar trend has emerged in the developing countries too[1]. Cancer is a large family of disease that involves abnormal cell growth which the potential to invade spread to other part of the body. [2]

In our society, the people who have cancer have a great risk of getting distressed, distress is nothing it is a kind of unhappiness or pain which affect the whole body and mind.[3] A certain amount of distress is normal for a patient with cancer but in some patients the distress level is too high.[4] These kind of distress needs proper assessment and treatment. The predisposing factors for distress are chemotherapy and radiation therapy. Chemotherapy is a drug or medication that is used to treat cancer, the main purpose of chemotherapy is to cure, control and palliates cancer.[5] The distress is mainly seen in patients as a result of the of the side effects of chemotherapy. The second choice of treatment in cancer is “Radiation therapy”. The radiation therapy is a treatment used against cancer and less commonly, thyroid disease, blood disorders and noncancerous growths. The radiation therapy is also sometimes used for nonmalignant cancer. The exact

mechanism of action of radiation therapy is unknown. But in a simple description, it breaks up the DNA of cancer cells. To disrupt their growth and division and even kill them.[6]

The major side effects are mainly [fatigue or lethargy, local irritation to the skin, hair loss and urinary problem]. These are the possibilities to increase the distress among patients with cancer. As a whole, we can say that the main reason for distress in cancer patients may be the result of chemotherapy and radiation therapy treatment.

This research study provides a strategy to assess the distress among patients with cancer undergoing chemotherapy and radiation therapy.[7] Finally, we highlight some of the points that remain to be addressed and propose several directions for future research efforts.

Material and Method

A nonexperimental descriptive design was adopted for this study. The nonprobability convenient sampling technique was adopted to select 100 samples of cancer patients. A standardized scale was used to collect data from cancer patients.

Findings:

Section I: Distribution of sample according to the distress level

Table 1: Distribution of sample according to the distress level

Variables	Radiation Therapy	Chemotherapy
Distress level		
0 – 4	24(46.2%)	28(53.8%)
5 – 7	18(56.3%)	14(43.8%)
8 – 10	8(50%)	8(50%)

Table 1 shows that patients facing distress which are well under control are more seen in chemotherapy, which is found to be 53.8% and seen less in radiation therapy and which constitutes 46.2%. The patients experiencing some distress are more found in radiation therapy (56.3%) than chemotherapy (43.8%). The patients experiencing high levels of distress are found to be equal in both radiation therapy and chemotherapy. All of a total the distress level is the same in patients receiving radiation therapy and chemotherapy.

Section II: Association between distress level and selected demographic variables

H_1: There will be a significant association between the level of distress and selected demographic variables.

Table 2. Frequency and percentage distribution showing the level of distress among chemotherapy and radiation therapy patients according to different demographic variables. N=100

Table 2 shows that there is no significant association between distress level and any demographic variables.

Discussion

Section 1: Demographic characteristics of the samples

Section 2: Distribution of sample according to the distress level.

Section 3: Association between the level of distress and selected demographic variables.

Section 1: Demographic characteristics of the sample: The results showed that the maximum percentage of the patients who receive radiation therapy and chemotherapy are >50 years of age and it is found to be 67.9% and 54% respectively. Almost 66% are males who receive radiation therapy and both males and females equally receive chemotherapy (25%).

A comparative study was conducted to assess the distress among chemotherapy patients based on gender. The majority of patients are women (64%) and men (36%). The mean age was 54.7 years men, women 54.5.[18]

A descriptive study conducted on patients reported distress in head and neck cancer patients receiving t radiation therapy cancer patients. The majority of people in the age group of 23-93 years old with a median of 67 years. In that majority are male (82.2%) female (17.8%) patients.[23]

Section 2: Distribution of sample according to the distress level: The patients facing distress which is well under control is more seen in chemotherapy, which is found to be 53.8% and seen less in radiation therapy and which constitutes 46.2%. The patients experiencing some distress are more found in radiation therapy (56.3%) than chemotherapy (43.8%). The patients experiencing a high level of distress are found to be equal in both radiation therapy and chemotherapy.

The study which was conducted in brazil reached to a conclusion that both genders the incidence of distress decreased over the course of an assessment. Comparatively, the incidence was higher among women (64%). They also reported problems in physical, family, emotional and spiritual domains. [18]

In the study which was conducted to assess the distress among head and neck cancer patients undergoing radiation therapy, a retrospective review was to identify patterns in patients who reported distress. The mean distress score ranged from 1.44-2.83.[23]

Section 3: Association between the level of distress and selected demographic variables.

There is no association between level of distress and selected demographical variables such as age, gender, marital status, educational qualification, occupation, type of cancer, stages of cancer, how long have you been suffering from this disease, type of treatment undergoing at present.

Conclusion

The overall findings of the study revealed that distress is common for all cancer patients and the treatment modalities (chemotherapy and radiation therapy) have no relation with the distress.

Ethical Clearance: Yenepoya Ethics Committee-1 approved our study protocol number 2018/056 titled "A comparative study to assess the level of distress among patients with cancer undergoing chemotherapy and radiation therapy in selected oncology centers Mangaluru on 28/5/2018 under the chairmanship of Dr. Vikram Shetty.

Total Elimination of Causes of Death in EAG and Non-EAG States of India

Chayanika Deka

Assistant Professor in Statistics, PDUAM, Eraligool, Assam, India

Abstract

Cause-specific mortality indicators give an insight into the public health scenario prevailing in the population. Reportedly a shifting pattern of causes of death has been witnessed in the past decades. Thus estimating gains in life expectancy after total elimination of specific causes of death will furnish sufficient evidence to prioritize according to the severity of these causes of death, in order to plan health policies. In this paper an attempt has been made to calculate percentage gain in life expectancy after total elimination of some selected causes of death in EAG and Non-EAG States of India for the periods 2001-2003 and 2010-2013. Results shows that over the study period effect of communicable diseases have reduced unlike non-communicable diseases.

Keywords: *EAG (Empowered Action Group)States, total elimination, cardiovascular diseases, diarrheal diseases, percentage gain in life expectancy.*

Introduction

Data on mortality by age, sex and cause are primary inputs for assessing population health status and a cornerstone of the evidence base for health policy in combination with other epidemiological and socio-economic information[1]. Time and again several studies conducted with a view to inspect the pace of several diseases that challenges an individual's vitality, reveals some of the facts which took shape in the recent decades that mortality rates related to non-communicable diseases like cardiovascular diseases (CVD), coronary heart diseases, diabetes and stroke have increased rapidly in the last decade with CVD having a major share[2]. From these studies, it has also been observed that the deaths due to infectious and parasitic diseases have drastically gone down during the last few decades[3]. Reportedly, communicable diseases have shown major declining trend but diarrheal diseases (DD) still remains a leading cause of death in the developing countries like India, claiming lives especially among children under five even though the deaths among children under-5 years have declined, the proportional mortality accounted by DD still remains high[4].

Estimates of the number of life years to be gained by elimination of specific causes of death provide an easy to grasp and powerful summary of the relative importance of these causes of death, as well as the potential benefits of intervention programmes[5]. Thus a comparison between the life expectancies obtained from the life table for all causes combined with those life expectancies obtained after total elimination of a specific cause of death will clearly reveal the severity of that particular cause of death as compared to other causes of death[6].

India is a vast country with vivid geographical and tropical conditions. Although it is a developing nation, the achievements and amendments in health and socio-economic conditions are not uniform within its states. India's Ministry of Health and Family Welfare has defined eight states as Empowered Action Group (EAG) states (Bihar, Jharkhand, Madhya Pradesh, Chhattisgarh, Uttar Pradesh, Uttarakhand, Odisha and Rajasthan) to facilitate focused effort to promote the reproductive and child health program. EAG states are those with high fertility rates and weak socio-demographic indicators[7]. Moreover, Assam has similar socioeconomic and demographic characteristics with respect to the EAG states[8]. The phenomenal increase in population has great impact not only on the demographic composition of the region but also has serious socio-economic consequences which gets reflected in political

turmoil and consequent conflicts witnessed in the entire region[9]. So, there is first need to study most vulnerable section of the country[8].

Therefore we set our objectives as follows: To estimate the percentage gain in life expectancy after total elimination for CVD and DD in EAG States including Assam and Other (Non-EAG) States (remaining major states) for the period 2001-2003 and 2010-2013 for both males and females.

Material and Method

For this study we used the data collected under Special Survey of Deaths (SSD)for the year 2001-2003 and 2010-2013[10]. We have also used the age specific death rates based on Sample Registration System (SRS)2001 and 2011, to construct general life tables for the year 2001-2003 and 2010-2013 for EAG States and Assam and Non-EAG States[11].

In the present study, we take into account two causes of death, namely, DD and CVD belonging to major categories of death, Communicable, maternal, perinatal and nutritional conditions (Group-I) and Non-communicable diseases (NCD) (Group-II) respectively in order to analyse the effect of elimination of these two causes of death on probability of death and human longevity. The remaining causes of death have been clubbed into one and classified as 'Other Causes of Deaths'.

Here for the construction of general life tables we have used the software MORTPAK-4. These life tables provide the total decrements ($_nd_{x,+}$) and probability of death ($_nq_x$) from all causes combined for each age group. Then we go for computing ratio ($_nr_{x,\alpha}$) of the observed deaths from the cause 'c_α' to all deaths in each age interval (x, x+n).

$$_nr_{x,\alpha} = \frac{_nD_{x,\alpha}}{_nD_{x,+}}$$

With this ratios and the total life table decrements $_nd_{x,+}$ already estimated, the distribution of life table deaths for each cause 'c_α' have been computed for each sex separately for the years 2001-2003 and 2010-2013 by using the approximation.

$$_nd_{x,\alpha} = {}_nr_{x,\alpha} \times {}_nd_{x,+}$$

Finally, we estimate the probability of death [$_nq_{x,(-\alpha)}$] after the cause of death 'c_α' being eliminated, by using the probability model given by Namboodari and Suchindran[6]

$$\frac{\bar{l}_\alpha(x+n)}{\bar{l}_\alpha(x)} = \left[\frac{l(x+n)}{(l(x))}\right]^R$$

Where $\bar{l}_\alpha(x)$ is the survival probability when the only effective cause of death is $C\alpha$

and $R = \frac{_nD_{x,\alpha}}{_nD_{x,+}}$

Then $_nq_{x,(-\alpha)}$ is given by

$$_nq_{x,(-\alpha)} = 1 - \left[\frac{l(x+n)}{(l(x))}\right]^R$$

We then construct life tables using '$_nq_{x,(-\alpha)}$' values for all other causes except the cause 'c_α' by the usual life table technique for males and females separately. These life tables provide the probable values of life expectancy denoted by $\overset{0}{e}_{x,(-\alpha)}$, that would be attained if the specified cause of death 'c_α' could be eliminated. The difference between $\overset{0}{e}_{x,(-\alpha)}$ and $\overset{0}{e}_x$, the expectation of life attained under the effect of all causes combined, would provide the gain in expectation of life after total elimination of the cause 'c_α'. The percentage gain in life expectancy is calculated by

$$\frac{\overset{0}{e}_{x,(-\alpha)}}{\overset{0}{e}_x} \times 100$$

Findings: The amount of increase in the life expectancy in different age groups after total elimination of various causes of death would obviously reveal the intensity of effect of those causes of death. Thetable 1 contains the percentage gain in life expectancyafter total elimination of CVDand DD for India, EAG States and Assam and Non-EAG States for both male (M) and female (F) for the periods 2001-2003 and 2010-2013.

Table 1: Percentage gain in life expectancy after total elimination of CVD and DD in EAG States and Assam and Non-EAG States for the periods 2001-2003 and 2010-2013

From table 1, it is seen that the overall percentage gain in life expectancy for both the study periods, the CVD have the maximum percentage gain in life expectancy followed by DD. It is observed that the elimination of the CVD would result in a good amount of increase in expectation of life. During the study period, the percentage gain in life expectancy have an increasing trend which is an indicative towards the fact that deaths accounted to CVD have risen. CVD are clearly stated as life style diseases as specific behavioral disorders such as physical in-activeness, regular intake of intoxicants like tobacco and alcohol and also unhealthy dietary habits are seen to be prevalent in today's population. of the 57 million deaths that occurred globally in 2008, 36 million – almost two thirds – were due to NCDs, comprising mainly CVD, cancers, diabetes and chronic lung diseases[12]. The combined burden of these diseases is rising fastest among lower-income countries, populations and communities, where they impose large, avoidable costs in human, social and economic terms[12].

Regional Disparity: From the table 1it is seen that in 2001-2003, percentage gain in life expectancy after total elimination of CVD in more than DD in case of Non-EAG states but its percentage gain in life expectancy is comparatively more than the EAG states. The difference in economic and population growth rates between the EAG states and other Indian states sharpened over the 1990s and since population growth in the EAG states was much higher than the Indian average in this period, the income disparity between the EAG states and India as a whole also increased[9]. Thus due to income disparity, people residing in EAG States and Assam might be less prone to the factors (as mentioned in the previous section) effecting CVD's unlike other states. In 2010-2013 similar trend is seen but percentage gain in life expectancy is more than the period 2001-2003 thus proving again that the severity of CVD has risen in the last decades.

Opposite pattern in results is witnessed in 2001-2003 for DD which is possibly the heath care facilities, proper sanitation or overall hygienic conditions are not at par in the EAG states and Assam as compared to the Non-EAG States. Unlike CVD, the percentage gain in life expectancy is less for DD in EAG states and Assam and also in Non-EAG states during the period 2010-2013 and these gains are less than the period 2001-2003. According to 2001 census[13] literacy rate of India was 64.83 percent which increased by nearly 10 percent (74.04 percent) during the 2011 census[14]. As the overall literacy rate increased it could be possible to make people aware about the vulnerability of the infectious disease like DD and its respective preventive measures.

Age Disparity: It is seen that if the CVD can be eliminated completely, the maximum percentage gain in life expectancy could be attained after age 40 for males and after age 50 for females. In Western countries where CVD is considered to be a disease of the aged, 23 percent of CVD deaths occur above 70 years of age while in India 52 percent of CVD deaths occur below 70 years of age[2]. It is noticed that the elimination of DD would increase on an average about 1 to 2 years gain in life expectancy at birth for both the male and female. The percentage gain in life expectancy after total elimination is more in the age groups 0-1 and 1-5 and also more in the age groups after age 50+.

Gender Disparity: Women experience a higher level of morbidity with acute diseases which are non-fatal and on the other hand, men experience higher rate of mortality with diseases that are life threatening and chronic[15]. During the study period 2001-2003 and 2010-2013 the sex differences in the results is quite evident as the percentage gain in life expectancy after total elimination of CVD is higher in males than females which is opposite for DD. This apparent gender bias may be enacted via parents being less likely to immunize, seek medical attention and/or being less likely to use appropriate antibiotic therapy for their sick female children[15].

Gender differences in the exposure to acquired risks can arise in several ways: (a) through differential exposure to hazardous activities related to one's job, adventurous activity etc; (b) through differential access to food and medical care; (c) through risk-prone health habits such as smoking, drinking, using drugs, rough driving and others[15]. Thus males being more prone to CVD might be due to differences in behavioral traits as compared to their female counterparts, males are supposed to be more exposed to intoxicants intake than females.

Conclusion

The prevalence of diseases might have changed as it seen that over the study period the percentage gain in life expectancy after total elimination of CVD is more in 2010-2013 than in 2001-2003. The casualties from DD might have diminished as the percentage gain in life expectancy is less in 2010-2013 than in 2001-2003. So it can be asserted that possibly the importance of Group-II causes of death has increased as compared to Group-I causes of death over the study period.

India has made steady progress in reducing deaths in children younger than 5 years, with total deaths declining from 2.5 million in 2001 to 1.5 million in 2012[16]. This remarkable reduction was possible due to the inception and success of many universal programs like widely practiced government aided programs on immunization, program for the control of DD, tuberculosis control programme,etc. Even though the deaths among children under-5 years have declined, the proportional mortality accounted by DD still remains high. DD is the third most common cause of death in under-five children, responsible for 13% deaths in this age-group, killing an estimated 300,000 children in India each year[17]. There would have been almost an increasing trend in gains in expectation of life at birth for males, had the causes of death CVD been eliminated completely. CVDs are the number 1 cause of death globally: more people die annually from CVDs than from any other cause[18]. Most CVD can be prevented by addressing behavioural risk factors such as tobacco use, unhealthy diet and obesity, physical inactivity and harmful use of alcohol using population-wide strategies.

Smartphones: An Appreciator or Depreciator in Youth Lives

Cresenta Shakila Motha[1], Sheila Christopher[2], Angel Selvaraj[1]

1Assistant Professor, 2Associate Professor, P.G & Research Department of Rehabilitation Science, Holy Cross College (Autonomous), Tiruchirappalli

Abstract

Technology has shrunk the world to a great extent. The mobile phones in our hand is a boon to the human kingdom connecting the near and far in a tremendous way and impacting each ones life in a diversified manner. The smart phones have played the role of an appreciator as well as depreciator particularly in the lives of the youth population. Usage of Smartphone often results in varied problems ranging from anxiety, stress, depressive symptoms and being aloof from the normal social stream. Increase usage of smart phones by youngsters has trapped them into compulsive web surfing, obsessive viewing of cybersex, relationships which are virtual and not truthful, information overload, playing games which are highly risky to their lives and that which are not educative. Compulsion of online shopping has resulted in youth being bankrupt because of unnecessary use of credit/debit cards not realizing the value of saving and leading aunhealthy life-style. This review article is an attempt to understand the role of smart phones in the lives of youth.

Keywords: *Technology, Smartphone's, Youth, Addiction.*

Introduction

In today's world, technology has become inevitable. As human beings have revolutionized, technology has advanced all these years. Consequently, it has changed the mode of living, communicating, travelling, purchasing, learning and many more. The necessity of technology is increasing day by day. Presently we have various looming technologies to achieve definite chores. The landline phones used in olden days are no longer on demand in this centenary. Since simplicity and more functionality has become indispensable these days.

A cell phone is a portative gadget which operates on cellular network mechanization to make and receive calls. The term smart phone denotes a cell phone with more advanced features other than calls, SMS and basic organic software. The first economic economically available cell phone called the Dyna TAC 8000x worth of $3995 was advanced by Motorola between 1973 & 1983. This huge 28 ounce cell phone is almost vague when compared to the devices used contemporarily. Though technology was improvised by human, presently it has outsmarted the human intellect. The present day's pocket sized tools are no less than a mini computer.

It has engrossed the whole world and enslaved the people of all ages.

Mobile Phone Addiction: Mobile phone addiction is a dependence syndrome which leads to problematic behaviors including preoccupation with communication, excessive time spent on mobile phones, adverse effects on relationship and anxiety if separated. The new term which is prevailing for mobile phone addiction is NOMOPHOBIA– no mobile phone phobia which was abbreviated in a study [(1)].

A study [(2)]claim cell phone addiction to be impertinence and pragmatism, Captivation over material objects combating intellectual, spiritual and cultural values and the hysteric use of mobile phones has been compared to that of credit card misuse and compulsive buying.

With a comprehensive receptiveness of cell phones among the budding generations now, teenagers are especially vulnerable to cell phones on social media.

Review of Literature

Positive Effects of Mobile Phones: In a study [3] about the positive effects of mobile phone on children the author enlightens the people with a few important useful points of mobile phones which includes i) staying connected with extended family and friends. ii) learning and exploring new things iii) Enhancement of child's knowledge and exchange of ideas. iv) development of technical expertise and practical understanding. These small sized, lightweight and portable devices are being very much used in today's world. She concludes that the user should know the limits as to what extent it should be used.

A detailed study on the impacts of mobile phones on people's lives has furnished that two-third of the phone users find it "a lot'' easier to stay connected with people around the globe. They also feel that mobile phones make them plan their daily routine easily and use their available time productively. One-third of the respondents consider their mobile phones as a time-saving device rather than a time-waster. They agree to the statement that their phones "save their time because they can always access the information they needed.'' Finally he summarized that just like two sides of a coin, the mobile phone is a device which offers both positive and negative impacts to its users [4].

The study by an unknown author outlines the positive side of mobile phones. It explains the uses of mobile phones in areas like Studies, Business, Entertainment and Communication and in emergency situations. In today's competitive business world and technologically booming educational scenario, it has become unimaginable to live without a mobile phone. It means that the mobile phones have become an indispensible device to execute day-to-day activities in today's changing lifestyle. In the field of entertainment too, mobile phones play a major role in enabling the users utilize their free time in keeping themselves entertained through movies, music, videos, games, etc. It is indeed a stress buster which enhances their work-life balance with enthusiastic entertainment.

Technology has been developed to make humans lives smooth and modernized. It is not just a mean of composure and poise but also an utensil to bring into light our presence. About social media, it is said that that it helps people to improve themselves get rid of intricacy and promotes positive approach towards social life. One need not be a gadget worm to upgrade themselves with the available applications rather must know as to how to balance between the various needs of life [5].

A Study [6]on positive impact of mobile phone on young people's social life expresses that the reason behind the usage of mobile phones is for the performance and micro co-ordination of their social life. The teenagers tend to leap above the rules laid by the family and relatives and prefer to use smart phones to stay connected with their friends. Smart phones play an important role in interpersonal relationship and are more convenient than the age old telephones as they are handy, portable and much more useful than the telephones. This provides more resilience in the lives of phone users and helps them in creating a flexible culture.

A report says that smart phones serve as a source of entertainment to people of young age and also acts as a personal assistant. It helps us to browse about things instantly anytime and anywhere. It causes less worry for parents as their children get to know more about the unknown details and learn alot new things through the internet facility available in the smart phones. The parents can also monitor their children from being both inside and outside the house. They always stay connected with their parents and this makes them less tensed about their kids. The author adds that the mobile phones can also help us in emergency situations and has also mentioned some of the very useful ways in his study like finding out the lost person through tracking systems, informing immediately over the phone to the police or the ambulance in case of an emergency and many more. Thus the mobile phones help us out in various means [7].

The Adverse Effects of Mobile Phones: An elaborate study [8] on the effects of mobile phones on kids highlights the bad effects in major domains. They include i) health hazards such as non malignant tumors, cancer and disturbed brain activity ii) affecting academics through game addiction, over indulgence in social media such as what sapping, etc. that would lead to poor attention, concentration, memory and time management of studies. iii) develop inappropriate behavior such as accessing pornographic sites, criminal behavior, etc. Lastly iv) using mobile phones as an aid for malpractice in exams.

An article on negative effects of social media on children emphatically portrays that cyber bullying – the dangerous and potentially fatal one, access to unwanted obscene harmful graphic websites, social media

addictions, wastage of time and inability to develop real human connect as the negative impact of mobile phones among the younger generation. She makes an appeal to the parents to spend some quality time with their children and educate them about the pros and cons of social media[3].

The adverse effects of using mobile phones in class rooms and its impact on learning and emotion – regulation style were examined through a small test[9]. It enabled to access the student's level of obsessiveness, nomophobia and mindfulness. The results highlighted the performance of students whose phone were taken away and those who possessed their phones could not perform well in the tests conducted. However researchers have concluded that mobile phone usage in class rooms can optimize learning to a certain extent.

A study puts forth the state of addicted teens in social media and networking [10]. It claims that about 70% of teenagers are accessed to smart phones with internet connection which means they have an open door to all sorts of distractions like viewing pornographic websites. Today's youth's mentality is that their status depends on the number of likes they get and when they get low it leads to bullying and stress. And the worst part is that they also use their phones while in bathroom and restroom. He concludes his study that all these activities exclude the individual from their family and friends since they find their smart phones and the social networking sites more interesting.

An elaborate study on how mobile phones are related to the chemical changes in our body during its usage was conducted [11]. The study says that whenever a smart phone is used, the reward center (ventral tegmental area) of the brain is triggered which leads to production of Dopamine. The major factors which cause the activation of this part are the games and new applications and finally these chemicals leads to addiction. This has a dangerous impact on the self-esteem of mobile phone users. Apparently people of this new age opt for smart phones for communication rather than conversing face-to-face with people. The study discovered that when a mobile phone was taken away or evacuated from the user, they showed symptoms similar to those who were deprived of alcohol, nicotine, etc. and this shows that mobile phone usage has become an "addiction" now-a-days.

An evident research on mobile phone addiction among the 21st century generation highlights the adverse effects of smart phones on mental health and well being and its aftermath which includes stress, anxiety and depression. A validated psychometric test was conducted for individuals aged 16 and above and was analyzed using Structural Equation Modelling. The results indicated that mobile phone addiction is a problematic issue across all ages and both genders. The study was concluded that the affected individuals may benefit from awareness and prevention efforts[12].

A detailed study [13] proposes the negative impacts of mobile phones on human health which brings in some of the most vulnerable hazards like i) eye tautness due to constant texting, reading, playing and concentrating on small graphics which leads to potential vision problems. ii) stress and sleep problems in both men and women because the notifications, vibrations, pop messages, etc. keeps them on the urge and causes unwanted distractions and depressions. iii) Germ Infestation through indirect means.

A research study in 2011 furnished that one in six mobile phones were contaminated with faecal matter and E.coli bacteria. iv) social disconnect because of over indulgence in phones and results in hampered family life and strained mental health.

A study on the impacts of mobile phones on student's life claims that mobile phones have become an indispensible device in this modern world and has turned out to be a popular electronic communication tool. A survey was conducted between boys and girls in colleges with regard to this study to expose the impact of mobile phones on youth peer relationships, family relationship and the institution. Through this survey, they consummated that mobile phone usage varied among the group of boys and girls. Boys handled mobile and studies in an equitable manner while girls were not able to balance between the two[14].

Positive and Negative Impacts of Cell Phones: Percentage of adult cell mobile owners who say that their mobile has.

Impacts	A lot	Some Extent	Only a little	Not at all
Made it easier to stay in touch with the people you care about	65%	17%	11%	6%
Made it easier to plan and schedule your daily routine	28%	19%	20%	32%
Made it easier to be productive while you are doing things like sitting in traffic, waiting in line etc.	26%	22%	21%	31%
Made it harder to forget about work at home or on the weekends	9%	10%	15%	24%
Made it harder to give people your undivided attention	7%	14%	26%	53%
Made it harder to focus on single task without being distracted.	7%	12%	24%	57%

Age Differences in the Impacts of Cell Phones: Percentage of cell owners who say that their phone has.

Conclusion

Every object has its own merits and demerits. We have reviewed the role of cell phones, its merits leading to a better and innovative world and its demerits leading to addiction and various health hazards like becoming a nomophobe. If used in a proper way it can be a lifeline where so many things can be attained in no time from any place whereas if not handled effectively it can be disappointing and annoying to the people around us. Unlike any addiction to substances this seems to be an invisible addiction. Whether some people consider it an addiction or not, it is slowly creeping into human's life as a cause of disturbance and stress rather than being a fruitful invention. This is a skyrocketing issue among people which has to be handled with utmost caution and care because a sudden deprival of mobile phones can lead to behavioral actions when done the same with alcohol and smoking. Moreover it is difficult to conduct study in this topic due to the similarity and complexity of terms related to it. Mostly all the studies conducted pertain to teens and youth. More researches have to be done on 'cell phone addiction in adults' too as of how it has become more or less like a contagious disease. Until then we cannot conclude how mobile phone plays a role as a vulnerable object to addiction.

A Study to Assess the Effectiveness of Meditation on Stress among Patients with Cancer in Selected Hospital at Mangaluru

Daisy D'souza[1], Gireesh G.R.[2]

[1]II[nd] Year M.Sc. Nursing Student, 2Associate Professor, Department of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be) University, Mangaluru, Karnataka, India

Abstract

Objectives: The objectives of the study were to assess the level of stress among patients with cancer, to evaluate the effectiveness of meditation on stress among patients with cancer and to associate findings between pre-test level of stress and selected demographic variables.

Method: Quasi-experimental non randomized control group design and an evaluative research approachwere carried out on 58 patients with cancer selected by non probability purposive sampling technique to test effectiveness of meditation. The data was collected by using perceived stress scale consist 10 items.

Result: The result showed that in pre test, the control group 3 (10.3%) of them had mild stress, 7 (24.1%) of them had moderate stress and 19 (65.5%) of the subjects had severe stress. In experimental group, 2 (6.9%) of them had mild stress, 6(20.7%) of them had moderate stress and 21 (72.4%) of the subjects had severe stress. In post test, the control group 3 (10.3%) of them had mild stress, 6(20.7%) of them had moderate stress and 20 (69%) of the subjects had severe stress. In the experimental group 15 (51.7%) of them had mild stress and 14 (48.3%) of the subjects had moderate stress. In experimental group the mean difference was (13.35) and it was more than the difference of the control group (0.42). The obtained p values of chi-square and likelihood ratio test were >0.05. Between the groups there was a difference in mean stress level and meditation is effective in reducing stress among patients with cancer as well as there was no significant association between pre test level of stress and demographic variables.

Conclusion: Anapanasati meditation proved to be effective in reduction of stress among patients with cancer in selected hospital at Mangaluru.

Keywords: *Stress, meditation, patients with cancer.*

Introduction

Cancer is an abnormal growth of cells which tend to proliferate in an uncontrolled way and, in some cases, to metastasize. One of the leading causes of death in the world is cancer.[1] Stress is a physical, mental or emotional factor that causes physical or mental tension. People experience symptoms like headaches, muscle tension or pain, chest pain, fatigue, change in stress drive, stomach upset, phobias, sleep problems, anxiety, restlessness, lack of motivation or focus, feeling overwhelmed, irritability or anger, sadness or depression, over-eating or under-eating, drug or alcohol abuse, anger outbursts, tobacco use, social withdrawal and exercise less often during stressed. Stress kills brain cells; a calm and quite environment permits their growth.[2] Meditation is considered as a type of mind body complementary medicine. Meditation can results in very deep state of relaxation and a tranquil mind.[3] Meditation

Corresponding Author:
Mr. Gireesh G.R.
Associate Professor, Department of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be) University, Mangaluru, Karnataka, India 575018

as a psychological, kinetic or hepatic intervention just as easily as a breath-related intervention for stress.[4] Patients with cancer those who regularly meditate have more clarity, insight and peace of mind which improves their overall well being and health. Meditation provides relaxation, balances nervous system activation, balances hormonal levels of body and increases brain coherence and as a result, body and mind no longer overreact to stressful stimuli. It also reduces the level of depression, anxiety and over-sensitivity and allows patients to cope with life in a better way and this is how the stress level comes down in patients with cancer.[5]

According to American Cancer Society, in the year 2017, there was an estimated 16,88,780 new cases of cancer have diagnosed and 6,00,920 cancer deaths in the US.[4] According to National institute of cancer prevention and research in India 2.5 million live with cancer, every year new cancer patients registered over 7 lakh and cancer related deaths are 5,56,400 in the year 2016. In Karnataka about 1.5 lakh cancer cases at any given time and about 35,000 new cancer cases are added to this pool each year.[6]

Materials and Method

The aim of the study was to assess the effectiveness of meditation on reduction of stress among patients with cancer in selected hospital. Evaluative approach and quasi-experimental non randomized control group design were adopted for the study. Fifty eight subjects were selected by Non-probability purposive sampling technique. The subjects were assigned to experimental and control group so as to include 29 subjects in each group. The level of stress was assessed by using perceived stress scale (PSS). Data were analyzed using descriptive and inferential statistics.

Findings:

Section I: Description of demographic characteristics of patients with cancer: This section deals with characteristics of 58 patients with cancer in terms of frequency and percentage. The sample characteristics are described under the headings of age, gender, religion, education, marital status, number of children, occupation, monthly income, presence of any habits, family history of cancer, type of treatment receiving for cancer and availing financial help.

The frequency and percentage distribution of demographic variables of patients with cancer showed that among 58 subjects, 27 (46%) belonged to the age 51-65 years and were female 30 (51.72%) and male 28 (48.27%). Majority 24 (41.37%) of them belongs to Hindu religion and had 21 (36.20%) primary school educational qualification. Majority 41 (70.68%) of them were married and had 30 (51.72%) more than 2 children. Most of the patients 27 (46.55%) were self employed and had 36(62.06%) 5000-10000 rupees of monthly income. Majority 24 (41.37%) of them were alcoholic and 23 (39.65%) of them were receiving radiation therapy treatment. Among 58 subjects, 29 (50%) of them had family history of cancer and 29 (50%) of them didn't have family history of cancer. Most of them 44 (75.86%) were receiving Govt insurance scheme for treatment as a financial help.

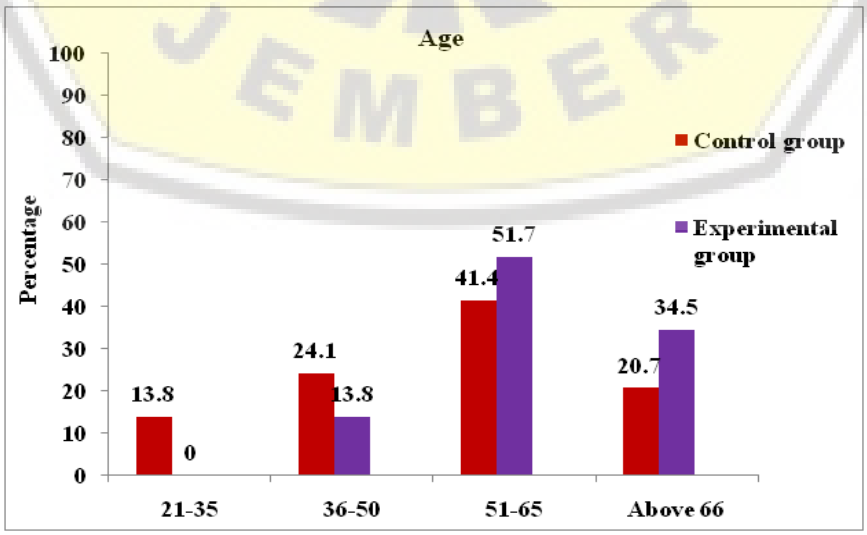

Figure 1: Bar diagram showing the age distribution of patients with cancer

Data presented in Figure 2 revealed that in control group majority of the patients belongs to 51-65 years that is 12 (41.4%), whereas minimum 4 (13.8%) belongs to 21-35 years. In experimental group majority of the patients belongs to 51-65 years that is 15 (51.7%), whereas minimum 4 (13.8%) belongs 36-50 years.

Section II: Comparison of pre test and post test level of stress in control and experimental group:

Table 1: Comparison of pre test and post test scores of stress in terms of frequency and percentage n=29+29

Level of stress	Pre test				Post test			
	Control Group		Experimental Group		Control Group		Experimental Group	
	f	%	f	%	f	%	f	%
Mild (0-13)	3	10.3	2	6.9	3	10.3	15	51.7
Moderate (14-26)	7	24.1	6	20.7	6	20.7	14	48.3
Severe (27-40)	19	65.5	21	72.4	20	69	-	-

Data presented in Table 2 shows that in pre test, the control group 3 (10.3%) of them had mild stress, 7 (24.1%) of them had moderate stress and 19 (65.5%) of the subjects had severe stress. In experimental group, 2 (6.9%) of them had mild stress, 6(20.7%) of them had moderate stress and 21 (72.4%) of the subjects had severe stress.

In post test, the control group 3 (10.3%) of them had mild stress, 6(20.7%) of them had moderate stress and 20 (69%) of the subjects had severe stress. In the experimental group 15 (51.7%) of them had mild stress and 14 (48.3%) of the subjects had moderate stress.

Section III: Effectiveness of meditation on reduction of stress among patient with cancer on pre test and post test level of each group:

Table 2: Effectiveness of meditation on pre test and post test level of each group in terms of mean, SD, paired‘t’ test and ‘p’ value n=29+29

Groups		Mean	SD	t	p value
Control group	Pre test	28.17	7.14	1.06	0.29
	Post test	27.75	6.81		
Experimental group	Pre test	29.31	6.27	13.11	0.001*
	Post test	15.96	5.72		

p <0.05 [*significant]df= 28

Paired “t” test was used to assess effectiveness of meditation on stress on pre test and post test level of each group. The above table 3 shows, in the experimental group, the mean post test score of stress among patients with cancer (15.96+5.72) was much less than the control group (27.75+6.81). Therefore H_{01} was rejected and H_1 was accepted, it indicates that meditation is effective in reducing the stress among patients with cancer.

Section IV: Effectiveness of meditation on reduction of stress between control and experimental group:

Table 3: Effectiveness of meditation on patients with cancer in terms of mean, SD, independent ‘t’ value and ‘p’ value obtained in experimental and control group n=29+29

Groups		Mean	SD	t	p value
Post test	Control group	27.75	6.81	7.13	0.001*
	Experimental group	15.96	5.72		

p<0.05 [*significant] df=56

Independent "t" test was used to compare the level of stress between control and experimental group. As per the table 4, in the experimental group, the mean post test score of level of stress among patients with cancer (15.96+-5.72) was much less than in control group, (27.75+6.81). In experimental group the mean difference was (13.35) and it was more than the difference of the control group (0.42). It indicates that between the groups there was a difference in mean stress level and meditation is effective in reducing stress among patients with cancer.

Section V: Association between pre test scores of stress and selected demographic variables: The present study obtained p values of chi-square and likelihood ratio test were >0.05 and itshows that there was no significant association between pre test level of stress and demographic variables. Hence H_{02} was accepted.

Conclusion

This study proved that stress is very common among patients with cancer especially 51-65 years of age. Most of the patients with cancer found with severe stress in selected hospital. There is a need for stress reduction by complementary therapies so that patients can live their life with happiness as much as possible. There is a need for health education to all patients with cancer as well as among general public to learn about complementary therapies and its effectiveness.

Sodium Hyaluronate Injection in Grade 2 & 3 Osteoarthriticpatients: A Two Year Follow Up Study

Deo Rishi Tripathi[1], Harleen Uppal[2], Deepak Kumar[3]

[1]Professor, [2]Ex Senior Resident, [3]Associate Professor, Department of Physical Medicine & Rehabilitation, PGIMER & Associated Dr RML Hospital, New Delhi

Abstract

Background & Aim: To analyse the long term (upto 2 years) clinical effect of viscosupplementation and diacerin administration in Osteoarthritic grade 2 & 3 patients in terms of physical function, stiffness, pain and adverse events.

Method: A retrospective analysis of patients having Osteoarthritis knee who underwent clinical routine protocol in the Department of Physical Medicine and Rehabilitation (PMR) of Dr. Ram Manohar Lohia (RML) hospital, New Delhi has been presented. The study incorporated 50 Osteoarthritis patients (28females, 22 males) having Osteoarthritis knee, grade 2 or 3 according to the Kellgren Lawrence Scale. Baseline Visual Analog Scale (VAS) and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) were recorded before the joint injection was given. The same were then recorded at 3 months, 6 months, 1 year and 2 years. Patients were injected with intra-articular injection of sodium hyaluronate, 90 mg/3 ml.

Results: The mean age of the patients was 65.4 years. The mean pain subscore, mean stiffness subscore and mean physical function subscore, all increased significantly between 0 to 3 months and 3 to 6 months (p value being 0.0001). However p value between 6 months to 1 year and 1 year to 2 years were statistically insignificant. There was no worsening of symptoms till 2 years.

Conclusion : In this study a single 3 ml/90 mg IA injection of Sodium hyaluronate was well tolerated and effective in providing statistically significant improvement from baseline in pain, stiffness and physical function subscore of WOMAC scale over 6 months period. However this improvement was not significant beyond 6 months upto 2 years follow up. But the knee in terms of pain, function and stiffness didn't worsen also, hence implying the condition remaining stable till 2 years after injection.

Keywords: *Osteoarthritis, Hyaluronic Acid, Viscosupplementation, Visual Analog Scale.*

Introduction

Osteoarthritis is one of the most common joint disease affecting the geriatric population apart from being the most common form of arthritis worldwide.[1] Most common joints involved are hips, knees, spine and interphalangeal joints. Out of all, knee is the most common joint to be involved causing significant disability and affecting quality of life. [2, 3]

The normal synovial fluid mainly contains hyaluronic acid, a nonsulfated glycosaminoglycan[4] which is primarily responsible for joint homeostasis and rheological properties. Osteoarthritis constitutes degenerative and repair processes in the articular cartilage and subchondral bone along with osteophyte formation. Both the molecular weight and concentration of hyaluronic acid is decreased in Osteoarthritis.[4] It is very much appropriate to consider local therapeutic modalities for the affected joints since clinically

Osteoarthritis is usually monoarticular or oligoarticular. This would be helpful in avoiding adverse systemic effects.

In our study, we observed and analyzed the clinical effect of viscosupplementation along with diacerin on long term basis, until two years of follow up in 50 patients suffering from grade 2 or 3 Osteoarthriris according to the Kellgren Lawrence Classification of Osteoarthritis.

Aims and Objectives: To analyze the long term clinical effect of viscosupplementation and diacerin administration in Osteoarthritic grade 2 & 3 patients in terms of physical function, stiffness, pain and adverse events.

Material and Method

This was a prospective, nonrandomized, experimental pre-post efficacy study[4] conducted in a tertiary care hospital, in the Department of Physical Medicine & Rehabilitation in Dr. Ram Manohar Lohia Hospital, New Delhi.

Patients being diagnosed as having Osteoarthritis knee and fulfilling the American College of Rheumatology Criteria for diagnosis of Osteoarthritis were incorporated in the study. All the patients having Osteoarthritis Grade 2 or Grade 3 of target knee confirmed by an X ray and receiving viscosupplementation along with diacerin as treatment modality were incorporated in the study.

Patients who were more than 40 years of age and had Kellgren Lawrence Scale 2 or 3 were included in the study. Other inclusion critereas included, those being diagnosed with Primary Osteoarthritis of affected knee, having radiographic changes in tibiofemoral/ patellofemoral knee joint medially &/or laterally and not responding to conservative treatment modalities.

Patients excluded from the study were those having Secondary Osteoarthiritis of knee or having Kellgren Lawrence Grade of 1/Grade 4. Patients who have had surgery in the knee joint or any history of viscosupplementation were excluded from the study. Patients having either significant valgus/varus deformity of knee or ligamentous laxity or meniscal instability or sepsis in knee joint or chronic significant venous or lymphatic stasis in legs or clinically apparent tense effusion or hypersensitivity to components of Hyaluronic acid based injections in past 3 months were all excluded from the study.

Study Design: All eligible patients fulfilling the entry criteria described above were enrolled in the study after taking written informed consent from them.

Baseline routine investigations which comprised of Complete blood count, Random blood sugar, SGOT, SGPT, Blood urea, Serum Creatinine were conducted. This was a part of the basic protocol followed in our department. If patient did not have an X-ray of knee taken in the last 3 months, X-ray bilateral Knee (Antero posterior and Lateral views in the standing position) was taken as baseline. X-rays were analyzed by a single investigator to make the assessment of radiological joint space narrowing uniform.

Baseline VAS and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) were recorded before the joint injection was given.

For all patients the basic protocol of the department was followed which comprised of pharmacotherapy comprising of Diacerin 50mg once daily for a month followed by twice daily for two months, knee care, physical therapy and patient education.[5]

The study incorporated initial treatment phase with one intra-articular injection of sodium hyaluronate, 90 mg/3 ml, contained in a sterile prefilled syringe, from lateral approach. Before injecting the drug, joints were aspirated for any effusion. The part preparation comprised of preparing the knee with betadene followed by spirit. After an observation period of 30 minutes, patient was discharged on the same day. Following the injection, patients were asked to avoid excessive walking for 1 day and do ice fomentation over injection site. They were asked to report back immediately if any complication or adverse reactions occurred.

Next follow ups were conducted at 6 months,1 year and 2 years when both VAS and WOMAC were conducted.

Concomitant treatment in addition to medications were allowed except for chronic use of narcotics, systemic corticosteroids, local corticosteroids into any other joint, visco supplementation into any other joint other than knee.

Drugs that were allowed to be used by the patient were Paracetamol, Aceclofenac, Diacerin, Calcium Citrate & Calcium Carbonate, Glucosamine Sulphate with or without Chondroitin.

Statistical Test Applied: SPSS software was used for statistical analysis. Paired Student t-test was applied out to compare the mean differences in VAS and WOMAC scores. P <0.05 was considered statistically significant.

Findings: The study was conducted in 70 knees in 50 patients (who met the inclusion criteria) over a period of 2 years in the PMR department of Dr RML Hospital, New Delhi. Patients who had bilateral affection were 20 in number. Out of these, 22 patients were females. Hence Male: Female Ratio was 28:22. There were no confounding factors in demographic characteristics of the patients at baseline.

Mean age of patients was 65.4 years with a Basal Metabolic Index of 29. The mean deviation of knee osteoarthritis was 8.5 years. 40% of patients were bilaterally affected that is 20 patients. Most of the patients were having the disease for 2-3 years. There were total 22 patients having Kellgren Lawrence Scale 2, whereas 28 patients had Kellgren Lawrence Scale 3 Osteoarthritis.

Summary of results from Primary & Secondary outcomes assessment: In our sample population; the mean pain subscore (numeric rating scale = 0-20) of WOMAC was 13.24 at baseline. This became 7.00 at 3 months, followed by 5.50 at 6 months, 5.45 at 1 year and 5.35 at 2 years. The p value between 0 to 3 months and 3 to 6 months were statistically significant with p value being 0.0001. However paired difference between 6 months to 1 year and 1 year to 2 years were statistically insignificant.

The mean stiffness subscore was 4.10 at baseline followed by 3.11 at 3 months, 2.6 at 6 months, 2.7 at 1 year and 2.8 at 2 years. The p value between 0 to 3 months and 3 to 6 months were statistically significant with p value being 0.0001. However paired difference between 6 months to 1 year and 1 year to 2 years were statistically insignificant.

The mean physical function subscore was 35 at baseline, which increased significantly to 48 at 3 months. It became 49 at 6 months, 50.1 at 1 year and 50.24 at 2 years. The paired difference was statistically significant between baseline and 3 months and 3 to 6 months. Whereas the difference was insignificant between 6 months to 1 year and 1 year to 2 years.

Table 1: Change of WOMAC pain score from baseline.

	0 months	3 months	6 months	1 year	2 years
Mean ±SD	13.24 (2.26)	7.00(1.5)	5.50 (1.6)	5.45 (1.6)	5.35 (1.5)
P value		< 0.0001	< 0.0001	0.10	0.09

Discussion

For time immemorial people have been researching about hyaluronic acid. Animal studies on Hyaluronic acid were conducted in late 1960's by Rydellet al[7] for Osteoarthritis in horses after joint injuries. Hyaluronic acid was first used in human joints (Balazeet al[8], Rydell et[7] al, Hyren et al, Marshall et al) in Japan and Italy. In 1993, Balazeet al[8] expressed the term viscosupplementation for the first time. Hyaluronic acid, which is a copolymer of repeating disaccharide units of D- Glucuronic acid & N- acetyl D glucosamine has concentration in the joints of young adults of about 3.8 mg/ml. However over a period of 30 years it drops down to around 2.5 mg/ml. Hyaluronic acid is secreted by beta synovial cells lining the synovial tissue & the normal knee contains 1-2 ml of synovial fluid. In patients who have failed conservative nonpharmacological treatment, Hyaluronic acid injections are indicated as per FDA.[6]

In a Cochrane review, by Bellamy et al[9], it was suggested that viscosupplements have fewer systemic side effects and have more prolonged effects than intraarticular corticosteroids. This review also concluded that viscosupplementation has definite benefits on pain, function and patient global assessment, especially at 5 to 13 weeks period post injection. Balazs et al[8] first proposed the concept of viscosupplementation and stated that intra-articular injection of hyaluronic acid could restore the rheological properties of synovial fluid, promote synthesis of hyaluronan and hence help in regaining mobility and decreasing pain. Evidence of advantages of hyaluronic acid primarily comes from animal studies and in vitro studies have concluded that hyaluronic acid has positive effects on chondrocytes, synoviocytes and on inflammatory cells that reach the synovial cavity in osteoarthritis. In vivo studies indicate that hyaluronic acid reduces pain by acting on cell receptors.[10] It has also been argued that hyaluronic acid preserves structure of chondrocytes and cartilage,[11]reduces synovial cell proliferation.[12,13]

Ghosh P et al have further postulated that hyaluronic acid binds to free radicals and removes them from joint cavity, hence reducing cartilage damage.[14]

A significant number of studies do report reduction in pain and improved function (not always significantly) that may persist for up to a year.[15,16] Similar results were found in our study stating that viscosupplementation did provide improvement in pain, stiffness and physical function subscore of WOMAC scale upto 6 month period.

Conclusion

In this study a single 3 ml/90 mg IA injection of Sodium hyaluronate was well tolerated and effective in providing statistically significant improvement from baseline in pain, stiffness and physical function subscore of WOMAC scale over 6 months period. However this improvement was not significant beyond 6 months upto 2 years follow up. Since the symptoms didn't worsen from 6 months till about 2 years of follow up period, hence the effect of viscosupplementation was quite effective till 2 years.

Awareness and Knowledge on Geriatric Dentistry amongst Undergraduates: Emphasis on the Special Care Dentistry in the Aging Realm

Divyalakshmi G.[1], Ramya R.[2], Niveditha Thampan[3], Priyadharshini Sk[3], Amritha James[3]

[1]Post Graduate Student, [2]Reader, [3]Post Graduate Student, Department of Oral and Maxillofacial Pathology and Microbiology, SRM Dental College, Ramapuram, Chennai, India

Abstract

Background: The emerging world has visualized an increase in the geriatric population percentage. There is a need for understanding and addressing the oral health needs of geriatric population. It is necessary for the future dentists to understand the nature of dental diseases, the difference in the behaviour of these diseases as well as the management.

Aims: The aim of this survey is to assess the awareness and knowledge of Geriatric Dental Care among undergraduate dental students.

Materials and Method: A descriptive cross-sectional questionnaire survey with 40-item questionnaire developed from guidelines by the European College of Gerodontology was conducted among the undergraduate dental students of the 4th and 5th academic year across 5 dental colleges in Chennai. 9 closed-ended 5-point Likert scale questions were also included to assess the importance of the existing barriers in elderly oral care.

Results: Out of 584 undergraduates, the percentage of students with unsatisfactory and satisfactory levels of knowledge was 57.6% and 42.4% respectively. In assessing the importance of barriers in providing dental care, communication skills of the doctor and the patient and transportation were ranked highest by the respondents.

Conclusion: The present study proves the significance of dental health care of the geriatric population and should be integrated with dental curriculum.

Introduction

The cycle of life and death is the constant transitions of nature. Ageing is a chronic process wherein the human body experiences constant wear and tear leading to decrease in the performance of routine activities of an individual. Over several eras the field of science, medicine and technology has evolved leaps and bounds such that the evading medical casualties seemed possible. This in turn has given a hand in increasing the life expectancy rates of humans which is essentially a statistical measure of the average time an organism is expected to live, based on the year of its birth, its current age and other demographic factors.

World Health Organization (WHO) defines life

expectancy as; "the average number of years a person is expected to live on the basis of the current mortality rates and prevalence distribution of health states in a population". India is the second most populous country with 8% involving geriatric population. Life expectancy in India has increased from 62.3 years for males and 63.9 years for females in 2001-2005 to 67.3 years and 69.6 years respectively in 2011-2015. [1]

Due to this swift greying of the population, general health and oral health care presents with a variety of difficulties in terms of providing a comprehensive diagnosis and treatments. Ageing is constantly accompanied with systemic diseases that can negatively influence oral health [2]. Professionals encounter unique challenges to treat the rapidly growing population of the elderly, dependent home bound and nursing home bound residents. The basic perception and understanding of the medical and dental aspects of ageing, ambulation, independent living, socialization and sensory function of the elderly has to be inculcated in to the foundation years of dentistry.

Previous literature have investigated different barriers interfere with providing oral health care to older patients. Saunders et al. reported the primary barriers in geriatric dentistry at dental schools were the lack of trained faculty members, a crowded curriculum and fiscal concerns [3]. Multiple medical conditions, complexity of dental treatments and insufficient training are barriers that can result in dental practitioners' indecision to treat older patients[4,5]. Entwistle showed that the dentists' willingness to provide care for older people could be improved by adding geriatric care to the dental curriculum[6]. Another study emphasized the necessity of geriatric dentistry training courses at dental schools to address the needs of the vast elderly population in India.[7]

Thus this study deals and aims to determine the attitude, knowledge regarding geriatric dentistry in a future population of dentists allowing a small insight on the requirement of geriatric dentistry as a separate entity in the dental curriculum for the betterment of oral health care to the elderly.

Materials and Method

Study Design: A descriptive cross-sectional questionnaire survey was conducted among the undergraduate dental students of the 4th and 5th academic year across 5 dental colleges in Chennai.

Ethical Clearance and informed consent: The study protocol was reviewed by the institutional ethical and review committee. The questionnaires were administered to the 4th and 5th year students randomly along with a brief statement on the objectives of the study.

Proforma details: A 50-item questionnaire was developed from reviewing the existing literature according to the guidelines in gerodontology by the European College of Gerodontology and modified accordingly so as to validate the application of the questions developed[8]. 40 questions were included under different sections that is 14 for knowledge, 9 for attitude and communications, 16 for treatment and 2 for application of geriatric dentistry. To assess the importance of the existing barriers in elderly oral care 9 closed-ended 5-point Likert scale questions were given.

Pretesting the proforma: A pilot study including 30 participants was performed to determine the test-retest reliability of the survey questions. The respondents were asked for feedback on clarity of the questions and indistinctness the answers provided. No modifications were made in the questionnaire based as all the questions were easy to understand and relevant to the present situation.

Method: The responses were classified into "yes", "no". The scoring for the responses is as follows: 1 point for "yes," and 0 point for "no". The maximum attainable score was 40.

The questionnaire was distributed via online google forms. The sample size was selected based on the previous studies and keeping the power of the study as 80%. The Cronbach's alpha value for the questionnaire was found to be 0.8.

Statistical Analysis: Data was analysed using the Statistical Package for Social Science (SPSS) software package version 21. Frequency and percentage distribution were used to present qualitative data. Mean and standard deviation, t-test were used to study the relationship between variables. Statistical significance was considered at the (0.05) level.

Results

The total of 584 students were included in the study: males – 34% and females -66%, 4th year – 320 and 5th year 264 students. A total of 40 questions of the

survey analysed the knowledge, attitude and application of geriatric dentistry.

The questionnaire and responsesfor each question from both the 4th and 5th year is given in Figure 1. Knowledge on health care in relation to ageing and geriatric medicine was lacking in both 4th and 5th year dental students. The attitude towards geriatric care varied between the student populations.

The assessment of the importance of the existing barriers in elderly oral care contained 9 closed-ended 5-point Likert scale questions. The results are summarized in Table 1 and graphical represented in Figure 2(A). The most favoured answers - Follow up of the elderly patients after treatment, Compliance of elderly patient, Time consuming in terms of treating aged patients, Inadequate transportation services and Communication skills of both dentist and patient was important represented by the score 4. Financial ability of the patient, Lack of appropriate facilities for dental treatment in the community, Awareness and knowledge regarding oral health care by care givers and Inadequate knowledge of geriatric dental caregained a response of 3 (very little importance). Table 2 represents the scores on the knowledge and attitude of the respondents. Total score was categorized as satisfactory and unsatisfactory level of knowledge according to participant's responses. The highest score of 38 was taken and 50th percentile of this highest score is referred as cut-off value. That is 50% and more was considered as satisfactory knowledge.

6.	Communication skills of both dentist and patient	4.3 ± 0.5	4.4 ± 0.5	0.24
7.	Lack of appropriate facilities for dental treatment in the community	3.1 ± 0.5	4.0 ± 0.7	0.02
8.	Awareness and knowledge regarding oral health care by care givers	4.4 ± 0.3	4.6 ± 0.8	0.04
9.	Inadequate knowledge of geriatric dental care	4.4 ± 0.7	4.4 ± 0.7	0.5

Table 2: Percentage of the total scores on knowledge and attitude on geriatric dentistry

Categories of Knowledge and Attitude	N (184)	Percentage
Unsatisfactory	106	57.6%
Satisfactory	78	42.4%

Discussion

Present day census show that the dwelling, frail elderly population has tremendously grown worldwide due to advancements in science. This population require a specialized set of physical, functional, psychological and social needs. Thus modified versions of professional healthcare is required. This leads to the necessity of training health care professionals to increase their competency and attitude towards the geriatric population.

Geriatric dentistry is a separate speciality emphasized in the Western and European countries but is still in the stage of infancy in India. The current curricula doesn't include geriatrias a separate subject or a speciality. Since the students form the community of future health care providers for the aged population, understanding their attitude and knowledge towards elderly is vital. This current cross-sectional study is the first to be conducted in five dental colleges in Chennai. The current study was conducted to elucidate the attitude and knowledge of dental students belonging to the 4th and 5th year regarding care of the geriatric population. The study population included only the 4th and 5th year because of the varied durations in clinical experience which would be allowing the increased amount of exposure and communication with elderly individuals.

Results of this study showed that age range of the participants was 20-22 year of which 66% were females and 34% males. The questionnaire was adapted to fit the study population. There was no statistical difference in the knowledge and attitude scales between 4th and 5th year. Patil PG et al addressed the influence of early clinical exposure for undergraduate students on self-perception questionnaire on the different aspects of geriatric dental care with two different colleges from Japan and India and concluded that the average scores about own-perception of knowledge and competency about aging, medicine and communication skills were same in both India and Tokyo students. The Indian students were considered to have more subject knowledge, better communications, diagnosis and treatment planning due to early clinical exposure. [9]

The present study evaluated the knowledge and attitude of the student population. Most of the student population responses suggested that they possessed inadequate knowledge on general geriatric care. The percentage of students with unsatisfactory and

satisfactory levels of knowledge was 57.6% and 42.4%respectively. This points out to the fact that the skills of the future dentists have to be modified to provide proper care for elderly patients.

In assessing the importance of barriers in providing dental care, communication skills of the doctor and the patient, transportation were ranked highest by the respondents. The p value was evaluated and assessed for the significance levels showing that the understanding of the existing barriers between the 4th and 5th year were similar.

Fabiano et al reported that transportation, complex and overlapping priorities were given the high rates by the students which was consisted as the barriers to provision of dental care. [10]

Kiyak and Reichmuth examined the determinants of dental service utilization by the geriatric population and revealed that financially weaker section of the elderly were less likely to procure dental care.[11]

Sargeran et al mentioned that a short-term training program on geriatric oral health care may influence and impact on the students' knowledge and practice and supported on inclusion of geriatric dentistry course in the dental curriculum.[12]

Hatami et al surveyed the dental student's attitudes and knowledge of geriatric dental care in Iran. He concluded that only minor percentage of dental students had high levels of knowledge of geriatric dental care and attitudes toward elderly people. [13]

Thus the changing demographics challenges the health care system as the management of the elderly requires a different set of protocol. Hence the futuristic dental care professionals must have a sound knowledge, attitude and the ability to treat the frail community of elderly.

Conclusion

A positive attitude, sound knowledge in understanding and overcoming the barriers in health care system forms the key towards geriodontology. This can be achieved by introducing specialized training programme in the dental educational system. This study was able to evaluate a positive attitude with moderate levels of knowledge in geriatric dentistry. Thus presses for the fact of conducting more studies to evaluate the importance and awareness on geriatric oral care and also post training surveys to evaluate and to modify the programme in geriatric dentistry.

Ethical Clearance: Institutional Review Board committee.

Menstrual Knowledge and Hygiene among Adolescent Girls in Tamil Nadu: A Reticent Matter that Needs Openness

G. Dhanalakshmi[1], P.B. Shankar Narayan[2]

[1]Ph.D. Scholar, [2]Assistant Professor, Department of Social Work, Pondicherry University

Abstract

Background: Adolescent girls constitute about 1/5th of the total female population in the world. This period is marked with the onset of menarche. It is still considered as something unclean or dirty in Indian society. Awareness related to menstruation is highly essential to remain healthy.

Aims and Objective: The study focuses on the knowledge of menstruation and menstrual hygiene among adolescent girls.

Material and Method: It adopted a descriptive research design. Simple random sampling was followed. The data were collected using a structured questionnaire from adolescent college students in Madurai, Tamil Nadu, India. Results: seventy-seven percent of the respondents are not aware of the biological functioning that happens during menstruation. Menstrual hygiene was marked good but they are not having adequate knowledge on ill effects of using a sanitary pad.

Conclusion: The results suggest the need for social workers to ensure the utilization of exact health information regarding menstruation to the adolescent girls.

Keywords: *Adolescents, Menstrual knowledge, Menstrual Hygiene.*

Introduction

Menstruation is a phenomenon exclusive to women. Menstrual hygiene has not received sufficient consideration in reproductive health and has an impact on achieving Millennium Development Goals.[1]Menstrual hygiene scheme was launched by the Government of India in 2011 when Adolescent Reproductive and Sexual Health was included as a component of Reproductive and Child Health phase II in National Rural Health Mission. Menstruation is the periodic discharge of vaginal bleeding with the detachment of uterine mucosa after the manifestations of secondary sexual characteristics; it is the natural element of the reproductive cycle.[2] This cycle persists between 26 and 32 days for the uterus in protecting the fertilized ovum, the new cycle begins with the vaginal bleeding when the ovum is not fertilized. [3] On average, every female menstruates for 3-5 days every month. The length and blood flow vary for every woman and every month. [4] Menstrual hygiene refers to the hygienic practices followed during menstruation. It includes the usage and disposal of absorbent material and maintaining cleanliness to prevent infections, illness and other diseases. Unhygienic practices lead to reproductive tract infections.[5]Poor menstrual cleanliness increases vulnerability to infection. The accessibility to water and clean absorbent material is necessary to protect the health and to prevent infections. [6,8] Talking about menstruation symbolized as impure in society. Menstruation is encircled by a silence that does not allow discussion on it which results in ignorance and poor menstrual hygiene practices among females. [7] Menstrual health is also a part of health education that needs to give much importance.[2]

Method

The objective of the study is to know the knowledge and hygienic practices followed during menstruation among adolescent girls. It adopted the quantitative method and descriptive research design. The study population comprises of all the final year students studying in an autonomous women college Madurai, Tamil Nadu. Simple random sampling was followed. The sample size was 143. The data were collected using a structured questionnaire. It consisted of questions related to demographic details, awareness on menstruation and hygienic practices they follow during menstruation. Data were analyzed and interpreted using SPSS (statistical package for social science). The study was started after getting approval from the college. Purpose of the study was clearly explained to the participants. The informed consent was taken from the participants.

Results

Demographic details: The results show that 116(81%) respondents belong to the age group of 19-20 years and 22 (15%) respondents were above 20 years of age. The mean age of the respondents was 19.66. Majority of the respondents 137 (96%) belong to the Hindu religion. 77 (54%) respondents are living in rural areas and 66(46%) are living in urban areas. The type of family of 128 (90%) respondents was the nuclear family. Only 12 (8%) are living in a joint family. The monthly income of the 77 (54%) respondents were below 10000 and 42 (30%) respondent's family income was between 10000 and 20000.

Knowledge on menstruation: Table 1 depicts the findings of this section. This part of the questionnaire required respondents to give information on the level of knowledge regarding menstruation. Respondents were asked to indicate whether they are aware of the biological process that is happening during menstruation, 111 (78%) of the respondents answered, as they do not know. 90 (63%) respondents have no knowledge about menstruation before they attain menarche. However, 73 (51%) respondents reported that they attained classes in their schools regarding menstruation. Source of information of 100 (70%) respondents were the mother and for 26(18%) respondents it is their friends. More than half, 75 (54%) of the respondents answered the normal interval between two menstrual cycles as 28 days. More than half, 109 (76%) respondents are aware of the age of menarche, as 13 to 15 years and normal duration of the menstruation as 3to 5 days reported by 123 (86%) respondents. 125 (87%) respondents are aware that menstrual blood comes from uterus and 102 (71%) respondents believe that menstrual blood is unhygienic.

Table 1: Knowledge on menstruation (N=143)

Particulars	Frequency	Percentage
Aware of the biological process of menstruation		
Yes	32	22.4
No	111	77.6
Knowledge about menstruation before menarche

No	7	4.8
Don't know	13	9.2

Discussion

The source of information for 70% of the respondents was their mother, which is in line with the studies done by Langer,[9]Dambhare[7] and Thakre et.al.[6] In the present study, 63% of the respondents have no knowledge about menstruation before they attain

menarche. This finding is consistent with that of a study done by Yasmin et.al which reports 58% of girls were ignorant about menstruation before menarche.[1]The reaction to menarche of 52% was discomfort and 21% felt scared. This result is in agreement with the study by Bela Kothari that 70% of girls did not know about menstruation before menarche and had a shocking and frightening experience.[10]The study by Deo et al which says 42.5% urban and 55.4% rural girls were only aware of menstruation earlier to the attainment of menarche. [11]Majority of the respondents have knowledge about the age (76%), duration (86%) and interval (54%) of menstruation. Eighty-seven percent of the respondents are aware that menstrual blood comes from the uterus. This finding supports the verdicts of previous studies done by Santhi Sree (2018) which reports 75% were having adequate knowledge.[12]

The absorbent material used by 99% of the respondents was sanitary napkin and 85% of them reported the reason for using as comfortable. These results are in accord with a recent study by Channawarindicating that 91.2% used pads[13] and most of the respondents (77%) used sanitary pads in another study by Abhijit[14]. A study by Tarhane reveals 79% of girls used pads and the reason for chosen sanitary pads as the high availability and influence of television.[15] This outcome is contrary to that of Dasgupta et al who found in their study only 11.25% of girls used sanitary pads during menstruation.[16]This happened because of the different place of residence i.e. rural and urban. Vidya V P showed that 46% of girls prefer to use clothes and the reason for not opting sanitary pads as the high cost, shyness to buy and disposal problems.[17] Only 41% of the respondents change the absorbent material thrice a day and 36% changes only twice in a day. The disposal way of 93% of the respondents is putting in a dustbin. The previous study by Shanbhag also mentioned as 40% of girls change sanitary pad twice a day and 30% changes thrice a day.[18] In a study by Channawar also reported the majority 74% of girl's disposal method of used absorbent material as a dustbin. In the present study, 78% of the respondents have no knowledge about the biological process happening during menstruation. This is in contrast to the study by Ghimire, which says 70% of the girls had knowledge regarding concepts of menstruation.[19] It was surprising that 86% of the respondents think that using sanitary napkin, as absorbent material is hygienic. This result matched the other study by Langer, which says the complete sample in the study agreed the ideal material to be used during menstruation is sanitary napkins.[10]

The results of this study indicate that adolescent girls lack the knowledge of the biological part of menstruation. It is clearly understood from the finding that 71% of respondents believe that menstrual blood is unhygienic. In addition, they have poor hygienic practices in terms of absorbent material and disposal. The majority are using sanitary napkins and thinks that as hygienic, they are not aware of the side effects of using sanitary napkins. Sanitary napkins have to be changed for every three to four hours. However, the majority are changing only thrice in a day. It will have an impact on their health. sanitary napkins are made of dioxins are used to bleach the cotton/material used for making the absorbent core and it causes for side effects in the body such as pelvic inflammatory disease, ovarian cancer, immune system damage, impaired fertility and diabetes. Sanitary pads are made up of synthetic materials, which can cause blockage of wetness, which encourages bacterial growth. Synthetics and plastic additionally prohibit the free flow of air and might lure heat and moistness, probably promoting the expansion of yeast and bacterium in duct space. Dioxin accumulates within the body fat and might add up to the residual levels over time, efforts need to be undertaken to reduce exposure. Adolescents should not pay their health for convenience. To look at it with an associate environmental perspective, it harms the surroundings owing to the plastic used and therefore the chemicals accessorial thereto for the absorption of blood and adding fragrance.

Conclusion

Adolescent girls should be educated about the development of secondary sexual characteristics, the menstruation, its importance and implications on the body and mental health. The findings support the need to provide education regarding safe hygienic practices that should not harm them in the future. In addition to educating the adolescents and their parents about menstruation and hygienic practices, it is significant to discuss the use of safe hygienic products during menstruation. That is to create awareness and educate people about the health effects of using sanitary pads. Negative attitude disseminates the negative body image and it affects their self.

Effectiveness of an Intervention Bundle on Thirst Intensity and Dry Mouth among Patients Admitted in Intensive Care Units

Gulia Shikha[1], Kumari Vinay [2], Khatri Neetu[3]

[1]Assistant Professor, Amity College of Nursing, Amity University, Haryana, [2]Vice Principal, Chitkara School of Health Sciences, Chitkara University Punjab, Haryana, India, [3]Ex Faculty at Maharishi Markandeshwer College of Nursing, Maharishi Markandeshwe Deemed University, Mullana, Ambala, Haryana

Abstract

Aims: To assess and compare thirst intensity scores and dry mouth scores before and after administration of intervention bundle among patients in experimental and control group.

Settings and Design: The study was done in Intensive care units (Neurosurgical, Medicine, Step up and Surgery). A true experimental pre test post test control group design was used.

Method and Material: Total 60 patients with thirst intensity and dry mouth were selected using convenience sampling and were randomly assigned to experimental and control group using lottery method. Intervention bundle used in the study consisted of cold wet oral swabs to wipe oral cavity and cold water mouth spray. Intervention bundle administered in two sessions with difference of thirty minutes between sessions to the experimental group patients.

Statistical Analysis Used: Analysis was done using SPSS 16.0 version. Descriptive and inferential statistics were used to analyse data in terms of homogenity, significance of result and association of thirst and dry mouth scores with selected variables.

Results: The findings indicated that both the groups were homogenous before administration of intervention bundle. After administration of intervention bundle in two sessions, the mean thirst intensity score was significantly lower in experimental group than control group. The mean dry mouth score was significantly lower in experimental group than control group. There was a significant association of patients' selected clinical variables with thirst and dry mouth in control group. Conclusion: Therefore, it was concluded that amelioration of thirst and dry mouth can be done by using a simple, effective and non pharmacological intervention bundle.

Keywords: *Thirst, Dry Mouth, Intervention Bundle.*

Introduction

Thirst and dry mouth are symptoms experienced by patients admitted in ICU as frequent impelling desire to drink water or any fluid whilst their stay. Intensive care unit (ICU) patients are exposed to many sources of distress such as pain, anxiety, fear, thirst, dry mouth, dyspnoea, immobility, nil per oral status, discomfort.[1] "Intensive care patients report thirst intensity as one of the most distressful of 10 symptoms; thirst is rated as the second prevalent symptom among patients. Thirst and Dry mouth are being the most neglected stressors during nursing care in ICU. A lot of factors which initiates the sensation of thirst and dry mouth in ICU : NPO status, anaesthetic drugs, narcotic drugs, diuretics, sedatives, high dose antibiotics, analgesics, multivitamins, age

more than 60 years, endotracheal intubation, surgical intra operative bleeding, altered intake output, emesis, hyperglycemia, altered hematocrit level, increased creatinine level, renal failure, heart failure, liver failure accelerates the physiology of thirst and dry mouth by enhancing it. [2] while patients do report about their intensity of thirst and dry mouth, still most of the time it remain untreated and undocumented by nurses, due to which stay of patients in ICU becomes uncomfortable and distressful. Thirst intensity and dry mouth are not even assessed as part of nursing assessment in patients which may lead to some severe complications like: increase in intensity of pain and dyspnoea.[3]

There is a lack of evidence based interventions and practices in hospitals to reduce the intensity and distress of thirst and dry mouth among patients admitted in ICU. There are no assessment strategies which are followed by staff nurses to assess thirst intensity and dry mouth. Therefore, it is an alarming need to view and observe thirst and dry mouth as distressful symptoms and by keeping that as one important factor, this study has been done, consisting of an intervention bundle with an aim to the decrease thirst intensity and distress and dry mouth among critically ill patient. In that view, a clinical trial was done, An experimental study to evaluate the effectiveness of an intervention bundle on thirst intensity and dry mouth among patients of selected units of MMIMS & R and Hospital, Mullana, Ambala, Haryana.

Objectives of the study were:

- To assess and compare thirst intensity scores before and after administration of intervention bundle among patients in experimental and control group.
- To assess and compare dry mouth scores before and after administration of intervention bundle among patients in experimental and control group.
- To determine the association of thirst intensity and dry mouth among patients with selected variables in experimental group and control group.

Subjects and Method: A true experimental pre test post test control group design was used.

The Convenience sampling technique was used to select the setting for study. Medical Intensive Care Unit, Neurosurgical ICU, Step Up ICU, Respiratory ICU and a total of 60 patients were also selected. The selected patients were randomly assigned to experimental and control group using lottery method, 30 in experimental group and 30 in control group. Interview technique was used to collect data for assessment of thirst intensity scores and Observation technique for assessment of dry mouth scores of patients admitted in intensive care units.

Ethical approval to conduct the study was obtained from Institutional Ethical Committee of MMIMS & R Mullana, Ambala, Haryana. Written informed consent was obtained from the study subjects regarding their willingness to participate in research project.

Intervention Protocol: Intervention bundle used in the study consisted of oral swabs, cold water spray squirt bottle, Dental Mirror, sterile artery forceps, sterile bowl and Distilled water.

Experimental Group-patients were explained regarding administration of intervention bundle. Assessment of patients' mouth and lips was determined firstly. Intervention bundle consisted of sterile cold wet oral swab wipes and sterile ice cold water sprays administered for in two sessions of 15 minutes each. First session was given in 15 minutes, patients received cold wet oral swab wipes in oral cavity 2 to 3 times and mouth spray with 5 to 6 sprays. A maximum of 9 wipes and 18 sprays of sterile water. After administration of intervention bundle, Post test 1 was taken after 15 minutes observation with the same tools. Then researcher waited for 15 minutes after post test 1 and session two was administered in 15 minutes with a maximum of 9 wipes and 18 sprays of sterile water. Post test 2 was taken after 15 minutes of session two.

Control group: control group was not given any intervention. Sample characteristics and clinical data (variables) were recorded in record sheet and thirst intensity and dry mouth scores were assessed only. After 30 minutes of pre test scores, post test 1 was taken and data were recorded. Then after, 30 minutes of post test 1, post test 2 was taken and data were recorded.

Intervention to the control group was given after accomplishment of Post test for ethical consideration.

Thirst intensity scale and dry mouth assessment scale were used to assess thirst and dry mouth of patients.

Data Analysis: Data was analysed using SPSS 16.0.

The data was analyzed and interpreted by employing descriptive and inferential statistics. Level of significance for the present study was taken as $p \leq 0.05$.

Results

The results of the study were Experimental and control group were homogenous and comparable in terms of demographic and clinical variables.

Both the groups were homogenous and comparable in terms of thirst intensity and dry mouth before the administration of intervention bundle with p value 0.13 and 0.38 for Thirst Intensity and dry mouth scores respectively among both groups.

Independent't' test was applied and the mean difference in thirst intensity scores between experimental group and control group was found to be statistically not significant (t=1.538, p=0.13) and the mean difference in dry mouth scores between experimental group and control group was also found to be statistically not significant (t=0.92, p=0.35) at 0.05 level of significance in pre test. Therefore, it can be concluded that the patients in experimental and control group had similar thirst intensity scores before the administration of intervention bundle.

Association of thirst and dry mouth was calculated with demographic and clinical variables to know which particular variables were having significant effect on increasing thirst and dry mouth among patients admitted in ICU. Patients with renal system diagnosis had increased thirst intensity in experimental group (p=0.009**). Patients with Gastrointestinal system diagnosis (p=0.009**) and Patients having drainage tube (0.009**) had increased dry mouth scores in experimental group thirst intensity score was higher in age group of 26-45 years group age in control group (f=3.076, p=0.043). F value is ANOVA value (ANOVA was applied for association, By F value, p vlue was calculated.) Patients who were on anti hypertensive drugs and having drainage tubes were having increased thirst intensity (p=0.100) in control group. patients who were on multivitamin drugs had increased thirst intensity (p=0.018*).

Table 1: Effectiveness of intervention bundle on thirst and dry mouth after session 1.

Variables	Group	Mean ±S.D	p value
Thirst Intensity	Experimental group	3.70±0.75	0.001**
	Control group	6.40±0.85	
Dry Mouth	Experimental group	0.97±1.24	0.001**
	Control group	2.60±0.28	

Thirst intensity and dry mouth scores of patients reduced significantly after session 1, the scores of post test 1, mean thirst intensity score was significantly lower (p=0.001**) in experimental group (mean=3.10±0.75) than control group (6.70±0.85) whereas mean scores of dry mouth was significantly lower (p=0.001**) in experimental group than control group. 0.001 p - value indicates that intervention is effective in decreasing thirst and dry mouth.

Table 2: Effectiveness of intervention bundle on thirst and dry mouth after session 2

Variables	Group	Mean ±S.D	p value
Thirst Intensity	Experimental group	3.10±0.75	0.001**
	Control group	6.70±0.59	
Dry Mouth	Experimental group	0.37±0.85	0.001**
	Control group	3.67±0.84	

Thirst and dry mouth scores again reduced significantly after administration of intervention bundle session 2, mean thirst intensity score in experimental group was significantly lower (p=0.001**) than the mean scores in control group whereas mean dry mouth score in experimental group was significantly lower (p=0.001**) than control group.

Table 3: Repeated Measures ANOVA showing comparison of thirst intensity score: pre test to post test 1 and post test 2 score in experimental group and control group.

Group	Time points	Mean±SD	F value	p- value
Experimental group	pre test	6.57±0.56	248.40	0.001**
	post test 1	3.70±0.75		
	post test 2	3.10±0.75		
Control group	pre test	6.33±0.60	6.0	0.004
	post test 1	6.40±0.85		
	post test 2	6.70±0.59		

The difference in mean thirst intensity scores at three points was compared using repeated measures ANOVA (RM ANOVA) . The difference in the mean thirst intensity scores at three points of time was found to be statistically significant (p=0.001**) in experimental group .

First session was given in 15 minutes, patients received cold wet oral swab wipes in oral cavity 2 to 3 times and mouth spray with 5 to 6 sprays. A maximum of 9 wipes and 18 sprays of sterile water. After administration of intervention bundle, Post test 1 was taken after 15 minutes observation with the same tools. Then researcher waited for 15 minutes after post test 1 and session two was administered in 15 minutes with a maximum of 9 wipes and 18 sprays of sterile water. Post test 2 was taken after 15 minutes of session two. Significant p value 0.004 in control group shows and explains that thirst and dry mouth intensity continuously increasing in patients. To know whether thirst intensity and dry mouth increases or decreases, RMNOVA was applied.

Table 4: Comparison of dry mouth score: pre test to 1st post test and 2nd post test score in experimental group and control group. N=60

Group	Time points	Mean±SD	F value	p-value
Experimental group	pre test	2.87±1.61	74.46	0.001**
	post test 1	0.97±1.24		
	post test 2	0.37±0.85		
Control group	pre test	3.20±1.12	5.32	0.008**
	post test 1	3.57±0.89		
	post test 2	3.67±0.84		

The difference in mean dry mouth scores at three points was compared using repeated measures ANOVA(RM ANOVA). The difference in the mean dry mouth scores at three points of time was found to be statistically significant (p=0.001**) in experimental group. Therefore, it can be inferred that the mean dry mouth scores of patients in control group were significantly different at three points of time and scores of dry mouth were decreasing significantly.

Table 5: Post Hoc test

Group	Three points time		M_D	SE_{MD}	p- value
Experimental group (n=30)	Pre-test	Post-test 1	2.86	0.17	0.001**
	Pre-test	Post-test 2	3.46	0.17	0.001**
	Post test 1	Post test 2	-3.46	0.17	0.001**
Control Group (n=30)	Pre-test	Post-test 1	-0.067	0.135	0.62
	Pre-test	Post-test 2	-0.367	0.089	0.001**
	Post test 1	Post test 2	-0.30	0.10	0.01*

LSD post hoc test was applied and pair wise comparison was done to find out where the significant difference occurred amongst three time points.

Thirst intensity decreased in experimental group between pre test scores and post test 1 scores, post test 1 scores and post test 2 scores. Hence, after administration of intervention bundle in patients of experimental group, thirst intensity significantly decreased. Therefore, intervention bundle was effective in reducing thirst among patients

Table 6: Post Hoc test

Group	Three points time		M_D	SE_{MD}	p- value
Experimental group (n=30)	Pre-test	Post-test 1	1.90	0.18	0.001**
	Pre-test	Post-test 2	2.50	0.27	0.001**
	Post test 1	Post test 2	0.60	0.16	0.001**
Control Group (n=30)	Pre-test	Post-test 1	-0.36	0.18	0.62
	Pre-test	Post-test 2	-0.46	0.17	0.01
	Post test 1	Post test 2	-0.10	0.05	0.83

The findings of LSD post hoc test also showed and confirmed that the scores of dry mouth were significantly decreasing where as in Control group scores were significantly increasing which assures the effectiveness of Intervention Bundle.

Dry mouth decreased in experimental group between pre test scores and post test 1 scores, post test 1 scores and post test 2 scores. Hence, after administration of intervention bundle in patients of experimental group, dry mouth significantly decreased. Therefore, intervention bundle was effective in reducing dry mouth among patients.

Discussion

The findings of this study states that patients in middle adulthood (age group 46-60 years) admitted in ICU or who are critically ill are more prone to experience thirst and dry mouth as symptom during their stay. More than One third (36.66%) of the patients in this age group were having thirst intensity and dry mouth. This finding is consistent with a study conducted by Nancy A stotts et al to identify predictors of thirst intensity in ICU which also concluded majority of patients were in age group of 46-60 years with mean age 55.7±14.5.[1]

The findings of the study that is showed significant decrease in mean thirst intensity (3.10±0.75) from pre test to post test 1 and post test 2 in experimental group (p=0.001**) and no significant decrease in mean thirst intensity score (6.70±0.59) in control group patients. There is also significant decrease in mean dry mouth (0.37±0.85) from pre test to post test 1 and post test 2 in experimental group (p=0.001**) and no significant decrease in mean dry mouth score (3.67±0.84) in control group patients. These findings are extremely consistent with a study conducted by Eun A Cho et al to assess effectiveness of ice chips on intensity of thirst and fluid intake in patients undergoing hemodialysis. The study showed results of significant decrease in thirst intensity

(2.28±0.85) from pre test to post test one and post test 2 in group 2 administered with ice (p=0.001).[13]

Another study conducted by Patrícia Aroni et al evaluate simple and safe strategies to mitigate thirst in the immediate postoperative period. The results of the study showed a significant decrease in thirst intensity in patients administered with ice from initial score 5.1 to 1.51. The findings of the present study also showed significant decrease in thirst intensity after administration of intervention bundle (cold water wet swabs and ice cold water spray), mean thirst intensity (3.70±0.75) in experimental group and no significant decrease in mean thirst intensity score (6.40±0.85) in control group.

In the present study, administration of Intervention bundle in experimental group significantly decreased mean thirst intensity (3.70±0.75) scores (p=0.001**) and mean dry mouth scores (0.37 ±0.85)(p=0.001**). The findings of the study are consistent with another study conducted by Arai SR et al to assess effectiveness of intervention bundle on thirst intensity and dry mouth. The findings revealed significant decrease (p=0.001**) in thirst intensity in experimental group than control group. The findings of the study also showed that the Usual Care group was 1.9 times more likely to report dry mouth compared to the Intervention Group for each additional assessment ($p < 0.04$).[12]

Conclusion

Thirst and Dry mouth are being the most neglected stressors during nursing care in ICU and post operative recovery unit. The present study focuses on assessment of thirst and dry mouth in critically ill patients and also association of clinical variables of patients with thirst and dry mouth. Proper dissemination of information should be done regarding the beneficial effects of ice cold water in reducing thirst and dry mouth of ICU patients

The study concludes that intervention bundle was effective in decreasing thirst intensity and dry mouth among ICU patients and also importance of integrating a practice of routine protocol to assess thirst intensity and dry mouth among critically ill patients at frequent intervals.

Thirst intensity and dry mouth should be monitored and evaluated as a part of the ICUs' quality management program, utilizing a variety of quantitative and qualitative approaches.

Conflict of Interest. No conflict of Interest.

Funding: No source of funding.

Ethical approval to conduct the study was obtained from Institutional Ethical Committee of MMIMS & R Mullana, Ambala, Haryana.

The study have also been registered under clinical Trials. gov NCT03215251.

Minimally Invasive Surgical Techniques– An Emerging Trend in Periodontics: A Review

J. Hemashree [1], Nashra Kareem[2]

[1]Under Graduate Student, [2]Assistant Professor, Department of Periodontics, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Minimally invasive dentistry is a concept that preserves dentition and supporting structures. However, minimally invasive procedures in periodontal treatment are supposed to be limited within periodontal surgery, the aim of which is to represent alternative approaches developed to allow less extensive manipulation of surrounding tissues than conventional procedures, while accomplishing the same objectives. In this review, the concept of minimally invasive periodontal surgery (MIPS) is explained.

Keywords: *Surgery, Periodontitis, Incisions, Flap, Bone.*

Introduction

Periodontitis is defined as the inflammation of the periodontal tissues that is present beyond the gingiva and causes the destruction of the attachments of connective tissue. If a periodontal disease occurred, we can opt for therapies to treat them. Periodontal therapy ideally arrests the progression of the disease and can regenerate the lost attachment apparatus of the connective tissues. Since the early 1980s it has become quite evident that minimally invasive techniques for intervention in some areas have produced lesser complications with a reduced risk of patient morbidity.(1) This has given rise to the idea of minimally invasive (MI) treatment primarily aiming at minimizing trauma of any interventional treatment and also at the same time achieving satisfactory therapeutic results.(2) More and more procedures are being re-evaluated worldwide with a view to reducing operative trauma. Due to its better advantages clinicians attempted to perform more procedures as minimally invasive as possible .

This same concept has been advented into dentistry under the broad term " MINIMALLY INVASIVE SURGICAL TECHNIQUES "(MIST) in periodontal therapy. Intrabony defects are treated with periodontal regeneration using various principles . These include

- Use of barrier membranes,(3,4)
- Demineralized freeze-dried bone allograft,(5)
- A combination of barrier membranes and grafts (6,7) and
- Enamel matrix derivative (EMD)(8,9)

Data from clinical trials and meta-analyses establish that these approaches provide benefits in terms of clinical attachment level (CAL) gain and probing pocket depth reduction as compared with access flap alone.

History of MIST: Minimally invasive surgery is a surgical approach for performing a bone grafting procedure utilizing a much smaller incision than has been traditionally used.

Initially, harrel and Rees (1995) proposed the minimally invasive surgery (MIS) with the aim of producing minimal wounds, minimal flap reflection and gentle handling of the hard and soft tissues.

Cortellini and Tonetti (2007) proposed a papilla preservation flap in the context of a minimally invasive, high-power, magnification-assisted surgical technique,

in order to provide even greater wound stability and protection and to limit further patient morbidity.

Rationale Behind MIST:

- Reduction of operative trauma
- Increase in wound stability
- Increase in flap stability
- Improvement of primary closure of wound
- Reduction of surgical chair time
- Reduction of postoperative discomfort for the patient
- Reduced recovery time

Indications for MIST:

- Isolated, interproximal bone defect, not extending beyond the interproximal site
- Periodontal defects in the borders of edentulous areas
- Periodontal defects that extend buccally/lingualy from inter proximal site
- Multiple separate defective sites in a single quadrant.

Contra-Indications for MIST:

- Generalized horizontal bone loss
- Multiple interconnected vertical bone loss

Considerations for MIST:

- All incisions are designed to conserve soft tissues
- Separate incisions are performed, continuous incisions are avoided
- Vertical releasing incisions are avoided
- Coverage of graft/membrane by soft tissue is achieved to promote periodontal regeneration, for example, if the bony defect is in esthetic areas, incision is given in palatal papilla[10]
- Tissues are reflected by sharp dissection or combination of blunt and sharp
- Adequate visualization of the procedure requires magnification and light source. Surgical microscope, loupes ×3.5 magnification can be used.
- Root surface debridement becomes difficult as minimal flap reflection is performed to preserve tissues. Mechanical debridement can be performed using the tip of curette inserted vertically and shank held parallel to the tooth surface. Ultrasonic scalers can be used to remove the granulation tissues
- Placement of bone graft material – plastic plunger gun can be used for precise placement of graft material
- Interproximal site can be closed by vertical mattress sutures. 6-0 resorbable suture can be used.

Techniques

The most popular MIS techniques are as follows:

Conventional papilla preservation flap[11]: This technique was introduced by Takei et al . The objective of this method is to to keep the papilla intact in areas with more than 3 mm interdental spaces. This method uses sulcular incisions around each tooth. In this method there is no incision being made through the facial interdental papilla, but with a sulcular incision on the lingual/palatal flap along each tooth with a semilunar incision made across each interdental papilla. This incision dips apically from the line angles of the tooth so that the papillary incision line angle is at least 5 mm from the gingival margin allowing the interdental tissues to be dissected from the lingual or palatal aspect so that it can be elevated intact with facial flap.

Modified papilla preservation flap[12]: Cortellini et al. proposed this design as a modification of the conventional papilla preservation flap. It was popularized by Cortellini as MIST. A horizontal incision is traced in the buccal gingiva of the interdental space at the base of the papilla and the papilla is elevated toward the palatal aspect. This technique is most suitable for interdental papilla which are thick and interdental spaces which are wide.

Simplified papilla preservation flap (modified minimally invasive surgical technique) [13]

Further modification of the the above mentioned technique was given by Cortellini . This is because it is best suited for narrow interdental spaces (≤2 mm). An oblique incision instead of horizontal incision is traced across the buccal aspect of the interdental papilla and the papilla is elevated toward the palatal aspect.

Single incision to harvest subepithelial and de-epithelized connective tissue graft[14]: This is a technique to harvest connective tissue graft. It uses only a single incision . This incision is placed at an angle

of 90° to the bone with no epithelium removed. This facilitates the readaptation of the separated tissue.

Pinhole surgical technique [15]: Pinhole surgical technique was designed by Chao. He came up with this technique to overcome the problems associated with periodontal plastic surgical procedures which was done conventionally as It needed the use of releasing incisions, flap elevations, coronal approach for the entry incision and graft placement. An 2-3 mm of small horizontal incision is made in the mucosa covering the bone near the base of the vestibule, apical to the recipient site. A full-thickness flap is raised which is extended coronally and horizontally such that four papillae are involved. Suturing is not required at the entry incision.

Buttonhole technique [16]: This technique is widely used to correct of ridge deficiencies which are very mild in the sites of implant or fixed partial dentures. This causes to decreased flap tension allowing for more precise primary incision closure .

Single tooth flap technique [17]: Single tooth flap approach consists of a mucoperiosteal flap elevated on one side (buccal or oral), leaving the soft tissues on the opposite side intact. It is indicated in intraosseous defects involving the interproximal aspect and exhibiting limited to no extension on the lateral/palatal side.

Tunnel technique [18]: The procedure aims at creating a multi-envelope supraperiosteal bed for the placement of connective tissue graft under a pedicle flap without any external incision.

Flapless punch approach for socket preservation[19]: Flapless punch approach for socket preservation technique is preferred in areas with deficient amount of keratinized tissue. The rationale behind flapless approach is to isolate implant and/or grafted socket from oral cavity and also to obtain an inclusive Guided bone and tissue regeneration effect while preserving circulation and esthetic soft-tissue contours.

Indirect sinus lift procedure for sinus augmentation[20]: The technique involves 1-3 mm wide osteotomy site, minimal instrumentation with closed graft thereby requiring less time and expertise.

Complications:

Post-operative healing: The development of minimally invasive surgery has greatly reduced the amount of complications and side effects in the post-operative period. In the immediate post-operative period, the main problem is represented by the primary closure of the surgical wound. Following traditional regenerative periodontal surgery based on papilla preservation flaps, Cortellini and Tonetti (2000) reported 70% of primary closure of the surgical wounds .

Conclusion:

Many studies assure the effectiveness of MIST by the enhancement of clinical parameters and reducing patient morbidity, but there is still a need to confirm the effectiveness of such techniques in periodontal surgery when compared with other conventional ones.

Knowledge on Basic Life Support among Arts and Science Students

B. Jayabharathi[1], P. Keerthiga[2], V. Priyatharshini [2], Ogbonna Uchechi Eberechi [2]

[1]Professor, SRM College of Nursing, [2]B.Sc.(N) Students, SRM College of Nursing, SRM Institute of Science & Technology, Kattankulathur, Kancheepuram District–603203, Tamil Nadu, India

Abstract

Introduction: Basic life support (BLS) is the medical care which is used for victims of life threatening illnesses or injures until they can be given full medical care at hospital. It can be provided by trained medical personnel, including emergency, paramedics and lay persons who have received BLS training.

Aim: The study aims to assess the level of knowledge regarding BLS among Arts and Science students, SRM Institute of Science & Technology, Kattankulathur.

Methodology: Non experimental descriptive research design was adopted to assess the knowledge regarding BLS among Arts and Science students at SRM Institute of Science & Technology. 120 students who fulfilled the inclusion criteria were selected by using non probability convenient sampling technique. Structured questionnaires were used to assess the demographic variables and knowledge on BLS among students.

Results: The analysis revealed that, majority 107(89%) of students had inadequate knowledge regarding BLS, 13(11%) of students had moderately adequate knowledge and no one had adequate knowledge about BLS. The study results revealed that, there was no significant association found between the level of knowledge regarding BLS among Arts and Science students with demographic variables .

Conclusion: The present study concludes that, majority 89% of Arts and Science students had inadequate knowledge regarding BLS and no one had adequate knowledge about BLS. Since BLS is an important life saving techniques, teaching programme can be planned on BLS for Arts and Science students. Thereby their knowledge on BLS can be improved.

Keywords: *Knowledge, Basic life support, Arts and Science students.*

Introduction

Basic life support (BLS) is the medical care which is used for victims of life threatening illnesses or injures until they can be given full medical care at hospital. It can be provided by trained medical personnel, including emergency, paramedics and lay persons who have received BLS training. BLS is generally used in the pre hospital setting and can be provided without medical equipment.[1]

Many countries have guidelines on how to provide BLS which is formulated by professional medical bodies in those countries. The guidelines outline algorithms for the management of a number of conditions, such as cardiac arrest, chocking and drowning. BLS generally does not include the use of drugs or invasive skills can be contrasted with the provision of Advanced Cardiac Life Support (ACLS). The most laypersons can master

BLS skills after attending a short course. Fire fighter, lifeguards and police officer are after required be BLS is also immensely useful for many other professions such as they care providers, teacher and personnel and social workers especially working in the hospitals and ambulance drivers.[2]

Cardiopulmonary resuscitation (CPR) provided in the field increase the time available for higher medical responders to arrive and provide ALS care. An important advance in providing BLS is the availability for the automatic external defibrillator or AED. This improves survival outcomes in cardiac arrest cases. Healthy people maintain CABs by themselves. In an emergency situation, due to illness or trauma, BLS helps the patient ensure his or her own CABs, or assist in maintaining for the patient who is unable to do so. For airways, this will include manually opening the patient airway (head tilt or jaw thrust) or possible insertion of oral (oropharyngeal airway) or nasal (nasopharyngeal airway) adjuncts, to keep the airway unblocked patient. For breathing, this may include bleeding control or (CPR) techniques to manually stimulate the heart and assist its pumping action . About 75% - 80% of all out hospital cardiac arrest happen at home and approximately 25% of sudden cardiac arrest victim die without getting immediate basic life support so effective basic life support provide immediately after cardiac arrest an double the value between the life and death for a loved one.[3]

Studies have also identified differences in the quality of CPR/BLS performed by various health care providers. Often chest compression is performed in adequately with slow rates of compression and inadequate depth of compression. Previous studies of CPR/BLS knowledge and skills have focused on other main stream health professions. The certificate is designed to provide competencies, skills and knowledge necessary to respond effectively and safely in first aid situations.[4]

CPR provided in the field increases the time available for higher medical responders to arrive and provide ALS care. An important advance in providing BLS is the availability of the automated external defibrillator or AED. This improves survival outcome in cardiac arrest cases.[3]

Jones A Y(2014) a study was conducted to evaluate the performance of staff nurse in general hospital and nursing homes in a survey method. Result showed that 86% of the nurse performed CPR in bed without support and 55% had to turn their head or back to look at the ECG monitor during the procedure. This survey suggests that there is a need to review the support given to the nurses to ensure safe administration of CPR procedure in general ward management.[5]

Basic life support involves the external support of circulation and ventilation for a patient with cardiac or respiratory arrest through basic life support, rapid intervention is the key to success and critical in preventing biologic death of brain cells. It is important to remember that indicated good basic life support is better than basic life support but even bad basic life support is a million times better than no basic life support at all.[3]

The present study aims to assess the level of knowledge regarding Basic Life Support (BLS) among Arts and Science students at SRM Institute of Science & Technology, Kattankulathur, Kancheepuram district, tamilnadu".

Methodology

The research design chosen for the study was Non-experimental descriptive research design. The study was conducted at SRM College of Arts and Science Kattankulathur, Kancheepuram district. In this study, the samples constituted of students who were studying I year B.Sc. Physics and B.Sc. Chemistry.120 students those who fulfilled the inclusion criteria were selected by Non-probability convenient sampling technique. The inclusion criteria include a. Students who were willing to participate in the study, b. Students who were studying I year B.Sc. Physics and B.Sc. Chemistry, c. Students who were present at the time of data collection. The exclusion criteria include a. Students who underwent any online courses/short term courses on BLS.

Development and Description of the Tool: It consists of two sections. Section A comprised of structured questionnaire to assess the demographic variables of students which includes age, sex, educational status, family monthly income, previous knowledge about BLS and source of information.

Section B pertained to assess the knowledge on BLS among the students by Structured questionnaire. It consisted of 25 closed ended multiple choice questions. The correct answer of each question was allotted with one mark and the wrong answer for each question was allotted with zero mark. The scores were interpreted as adequate knowledge (>70%), moderately adequate knowledge (51-70%) and Inadequate knowledge (<50%).

Reliability of the Tool: Reliability of the tool was established by split half method. The coefficient correlation r = 0.75 which was very high. Hence, the tool was considered reliable and feasible for proceeding with the main study.

Ethical Consideration: The research proposal was approved by research committee of SRM college of Nursing, SRM university, Kattankulathur, Kancheepuram district. Permission was obtained from Dean, SRM College of Nursing and Dean, SRM College of Arts and Science. Informed consent was obtained from the study participants, after explaining the nature and duration of the study. Assurance was given to the individual that report will be kept confidential.

Results

Regarding the demographic variables of Arts and Science students, 60(50%) of students belonged to the age group of (17-18 yrs), 59(49%) were in the age group of (18-19 yrs), 1(1%) were in the age group of (19-20). Considering the sex, 59 (49%) were male and 61 (51%) were female. Considering the education, 66(55%) of students were studying B.Sc. . Physics and 54(45%)of students were studying B.Sc. Chemistry. Considering the family income, 13(11%) student's family income was Rs.1590-Rs.4726, 33(28%) of student's family income was Rs.4727-Rs.7877, 33(28%) of student's family income was Rs.7878-Rs.11816, 41(34%) of student's family income was Rs.11817-Rs.15753. Considering the previous knowledge on BLS, 82(68%) of students had previous knowledge about BLS and 38(32%) of students had no knowledge about BLS. Considering the source of information, 28(23%) of students have got information from media, 56(47%) of students have got information from relatives, 36(30%) students have got information from friends.

Table 1: Frequency and percentage distribution of level of knowledge on BLS among Arts and Science students N=120

S.No.	Knowledge level about BLS	No. of students (n)	Percentage Distribution %
1	Inadequate Knowledge	107	89
2	Moderately Adequate Knowledge	13	11
3	Adequate Knowledge	0	0

The analysis revealed that, majority 107(89%) of students had inadequate knowledge regarding BLS, 13(11%) of students had moderately adequate knowledge regarding BLS and no one had adequate knowledge about BLS.

Table 2: Association of level of knowledge regarding BLS among Arts and Science students with their demographic variables. N=120

S.No.	Demographic Variable	Class	Knowledge level about BLS		Chi-Square value	DF	P-Value
			Inadequate Knowledge	Moderate Knowledge			
1	Age in years	17-18 Years	54	6	0.230	2	0.892
		18-19 Years	52	7			
		19-20 Years	1	0			
2	Gender	Male	53	6	0.053	1	0.818
		Female	54	7			
3	Educational Status	B.Sc. Physics	58	8	0.252	1	0.616
		B.Sc. Chemistry	49	5			
4	Family Income Per Month	Rs.1590 - Rs.4726	11	2	1.192	3	0.755
		Rs.4727 - Rs.7877	31	2			
		Rs.7878 - Rs.11816	29	4			
		Rs.11817 - Rs.15753	36	5			
5	Previous knowledge about BLS	Yes	75	7	1.414	1	0.234
		No	32	6			
6	Source of Knowledge	Media	24	4	0.579	2	0.749
		Relatives	50	6			
		Friends	33	3			

The results revealed that, there was no significant association found between the level of knowledge regarding BLS among Arts and Science students with their demographic variables such as Age, Sex, Educational status, Family income, Previous knowledge about BLS and Source of information.

Discussion

Basic life support is a process of externally supporting the circulation and respiration of a person who has a cardiac or respiratory arrest in order to maintain life until advanced life support is available. The purpose of life support is for oxygenating the vital organs such as brain and heart until appropriate definitive medical treatment can restore the normal heart and ventilator action.[3]

In a normal and healthy individual, the life process can be achieved by the physiological and physical process on their own but there are certain moments like accidents which,need on the spot attention to pull the victim out of trauma or crisis. The occurrence of such the emergency is obviously unpredictable. Most of the time emergencies would be airway obstruction,apnoea, blood loss and cardiac arrest.[6]

The present results showed that, majority 107(89%) of students had inadequate knowledge regarding BLS,13(11%) of students had moderately adequate knowledge regarding BLS and no one had adequate knowledge about BLS. The results revealed that, there was no significant association found between the level of knowledge regarding BLS among Arts and Science students with their demographic variables such as Age, Sex, Educational status, Family income, Previous knowledge about BLS and Source of information.

Alafia (2014) conducted a study to assess the knowledge of basic life support among under graduate other medical personnel, clinical nurses and lay persons throughout turkey. The questionnaire investigated the demographic characteristics of the subject, the knowledge of the theoretical and practical aspects of basic life support and personal experience and attitudes related to basic life support. The findings are compared to the other participants, individuals with previous emergency experience and those who had previous basic life support training answered significantly more the theoretical questions correctly. However neither of those of these groups performed significantly better than the other participants in the practical questions.[7]

Sudden cardiac death is the most common cause of death in developed countries. In US the incidence of sudden death is 2,50,000 per year. Only 2% to 15% of the patients suffering from sudden cardiac reach the hospital. The risk of sudden cardiac death from coronary heart disease in adults is estimated to be about 1per,1000 adults of 35 years and older per year. So being trained to perform BLS can make the difference between life and death for a victim. Every students must know about this life support's in their life. This may help them to save the life of the individual.[8]

Effective BLS provided, immediately after cardiac arrest can double a victim's chance of survival. Death from cardiac arrest is not inevitable. If more people lives could be saved. CPR can restore circulation oxygen reach blood to the brain which can prevent permanent brain damage or death that occurs within 4-6 minutes. A person may need CPR which he suffers from drug overdose, heart attack, blood loss, stroke, drowning, electrocution, suffocation, chocking where the heart beat and breathing has to be restored. If a victim receives this crucial help of BLS in the form of mouth to mouth resuscitation and rhythmic chest compression, it can add vital minutes to his/her life while awaiting the arrival of an emergency medical technician.[9]

Conclusion

The study concludes that, majority 107(89%) of Arts and science students had inadequate knowledge regarding BLS and 13(11%) of students had moderately knowledge regarding BLS while none had adequate knowledge about BLS. BLS is generally for everyday life, in which it is used to resuscitate victims of threatening illness or injuries. It is generally used in prehospital setting and can be provided without medical equipment. BLS helps to ensure the CAPs. Since it is an important life saving techniques, teaching programme can be planned on BLS for Arts and Science students. Thereby their knowledge on BLS can be improved.

Effectiveness of Structured Teaching Programme on Knowledge and Practice of Safety for Women

Judy Mary Lyngdoh[1], Sadhana Chinchole[1], Chandrashekhar[1], Favour Ugomma Kalu[1], Monika Singh[1], Merlin Suji [2], Leeja Rajan[2]

[1]2nd Year P.B. B.Sc. Nursing Students, [2]Tutor, Symbiosis College of Nursing, Symbiosis International (Deemed University), S.B. Road, Pune, Maharashtra

Abstract

As India races towards becoming an economic superpower, the country is lacking in women's safety with an alarming number of women succumbing to road accidents and fire related deaths every year.(1) The present study aimed to evaluate the effectiveness of structured teaching programme on knowledge and practice of safety for women among female nursing students studying at selected nursing college in Pune city. Non-experimental descriptive design was used to assess the 122 female nursing students' level of knowledge and practice regarding 'women safety.' To select the samples, Non-Probability convenient sampling technique was used. After Pre-test structured teaching programme were implemented. Result have shown that structured teaching programme were effective in improving the knowledge and practices of female nursing students regarding women safety.

Keywords: *Women safety, structured teaching programme.*

Introduction

"You can tell the condition of a Nation by looking at the status of its Women." very rightly said by Jawaharlal Nehru. Comparing the status of women with the ancient times, women now can be seen everywhere in every field working shoulder to shoulder with men and now they are even holding high offices and big positions in Indian administration. Still the area where the nation is falling back and is lacking is the safety and security of Indian women. (2)

All woman has the right to live in her community without fear of violence. The situation is same in cities and rural areas. Its observed that those who are living in lower economic condition were more vulnerable to all sort of abuses against women. (3)

Women's safety includes strategies, practices and policies which strive to reduce or prevent violence against women, including women's fear of crime. It involves freedom of expression and prevent from exploitation. This includes safe of drinking water, the existence of communal toilet facilities, slum improvement, gender sensitive Street designs, safe shopping centers and public transport systems.(4)

Gender-based violence is present at various levels, beginning with discrimination at birth, further perpetuated through discrimination in education, nutrition, employment, wages and direct/indirect acts of sexual aggression."Moroccan women have the right to live a decent life just like men, without being raped, or suffering violence that prevents them from being fully involved in the country's political, economic and social life. We ought to work towards this end and change this reality; by doing so, we'll secure freedom and dignity for every woman and build a healthier society," Said by Amina Azatraoui(5)

The UN Declaration on the Elimination of Violence Against Women states, "violence against women is a manifestation of historically unequal power relations between men and women" and "violence against women is one of the crucial social mechanisms by which women are forced into a subordinate position compared with men."(6)

Statement of the Problem: A comparative study to evaluate the effectiveness of structured teaching programme on knowledge and practice of safety for women among female nursing students studying at selected nursing college in Pune city.

Objectives of the Study:

1. To assess the pre-test knowledge and practices regarding women safety among female Nursing students.
2. To assess the post-test knowledge and practices regarding women safety among female Nursing students.
3. To determine the effectiveness of structured teaching programme regarding women safety among female Nursing students.
4. To find out the association between pre-test level of knowledge with their selected demographic variables
5. To find out the association between pre-test level of practices with their selected demographic variables.

Operational Definitions:

Women safety: In the study women safety means the rules, regulations and actions taken by the people and the government to protect the women in the society.

Structured teaching programme: In this study it refers to systematically planned teaching programme designed to provide information to 122 female nursing students regarding as achieved by knowledge score.

Hypothesis:

H_{o1} = There is no difference between pre-test and post-test knowledge score regarding 'Women Safety' among female Nursing students studying at selected colleges in Pune City.

H_{o2} = There is no difference between pre-test and post-test practice score regarding 'Women Safety' among female Nursing students studying at selected colleges in Pune City.

$H_{o\ 3}$ = There is no association between pre-test and post-test score regarding 'Women Safety' among female Nursing students studying at selected colleges in Pune City.

Research Design: Research design will be non-experimental descriptive design to find out the effectiveness of structured education on college student's knowledge and practices regarding understanding of women's safety at selected colleges in Pune.

Population: In the present study, the population is comprised of the college students studying in different Colleges across Pune.

Sample and sampling technique: A non-probability convenient sampling technique was used for selecting 122 female nursing students who met the set criteria during the period of data collection.

The following criteria were set for the selection of samples:

Inclusion criteria:

- Nursing student of selected nursing institution
- Those who are available at the time of the study
- Those who are willing to participate

Exclusion criteria:

- Those who are not willing to participate
- Those who were absent during data collection

Data collection technique and instruments: A study aimed at evaluating the effectiveness of structured teaching programme on knowledge and practice of safety for women among female nursing students studying at selected nursing college in Pune city. To collect the data for present study, self-structured knowledge questionnaire and practice checklist was selected as constructed.

Development of the tool:

The tool was developed based on:

1. Related review of literature guidelines, journals, reports and articles published and unpublished studies) were reviewed and used to develop the tool.
2. Guidance and consultation with the guide and subject experts.
3. Objectives of the study

A self-structured questionnaire and checklist was developed to assess knowledge and practice of nursing students regarding women safety

Description of the tool: A tool consists of three sections as follows:

Section 1: Demographic variables (age, gender)

Section 2: Checklist to assess the practice of nursing students regarding women safety.

Section 3: Self structured questionnaire to assess the knowledge of nursing students regarding women safety.

Content validity: To ensure content validity of the tool it was submitted to 15 experts. Three from Obstetrics and gynaecological nursing, three from community health nursing departments, three from medical surgical department, three from Child health nursing department and three from Psychiatric department. The experts were selected based on their clinical expertise, experience and interest in the problem being studied. They were requested to give their opinion on the appropriateness and relevance of items in the tool. As a whole the suggestions and comments of experts included grammatical corrections of the sentences. The modified tool contained 5 items after incorporating the suggestions.

Reliability: To measure the reliability of the tool, Karl Pearson Test-retest was used to establish a reliability of structure questionnaire on knowledge and checklist on practice regarding women safety among female nurses' students. Reliability was satisfactory, value of practice is 0.92 and value of knowledge is 0.80

Data Collection: pre-test was taken followed by 1-hour structured teaching programme then post-test score is achieved.

Description of demographic variables: According to the data collected from the Samples, 9 (7.37%) samples were in the age group of 17-19 years, 79(64.75%)samples were in the age group of 20-22 years, 22(18.03%) samples were in the age of 23-25 years and 12(9.83%) samples were in the age group of 26 and above

Total number of the female Nursing students who have attended Workshop/Seminar/Conference on women safety were 42(34.42%) and 80 (65.57%) of the students did not attend any of it.

The above table shows that 18(14.75%) of the female Nursing student's parents earned between 10,000-20,000, 24(19.67%) samples patents earned between 21,000-30000, 36(29.5%) samples parents earned between 31,000-40,000 and 44(36.06%) samples parents earned between 41,000 and above.

The study revealed that 62(50.81%) of the Nursing students were Hindu, 46(37.7%) were Christian, 7(5.73%) were Muslim and 7(5.73%) of the Nursing students belongs to other religion.

Related to Academic level, 33(27.04%) of the Nursing students were 1st year B.Sc. Nursing, 35(28.68%) were 2nd year B.Sc. Nursing, 26(21.31 were 3 rd year B.Sc. Nursing and 28 (22.95%) were 4th year B.Sc. Nursing.

Regarding Parent education, 3(2.45%) of the nursing student's parents were illiterate, 49(40.16%) were below 12th standard 62(50.81%) were Graduated and 8(6.55%) were Post-Graduated and Above.

About Residence, 26(21.31%) of the nursing students were hosteller, 60(49.18%) were non-hosteller and 36(29.05%) stays with parent/relative.

Comparison of pre-test and post-test knowledge score on female nursing students regarding women safety: To test the statistically significant difference between the mean pre-test and post-test knowledge scores of the female Nursing students regarding women safety. the following null hypothesis was stated.

Hypothesis$_{-01}$: The mean post-test knowledge score is higher than the mean pre-test knowledge score of women safety.

Mean post-test knowledge score of the female nursing students regarding women safety (11.12) are significantly higher than their mean pre-test knowledge scores (4.74). In order to find out the significant difference between the mean score of pre and post-test knowledge score of the female nursing students regarding women safety paired 't' test was computed. The calculated value is higher than the table value (T-test value 31.65), the null hypothesis was rejected and the research hypothesis was accepted. Hence the researcher concluded that gain in knowledge is not by chance but by structured teaching programme on women safety.

Comparison of the pre-test and post-test practice score on female nursing students regarding women safety.

To test the statistically significant difference between the mean pretest and post-test practice scores of the female nursing students regarding women safety, the following null hypothesis was stated.

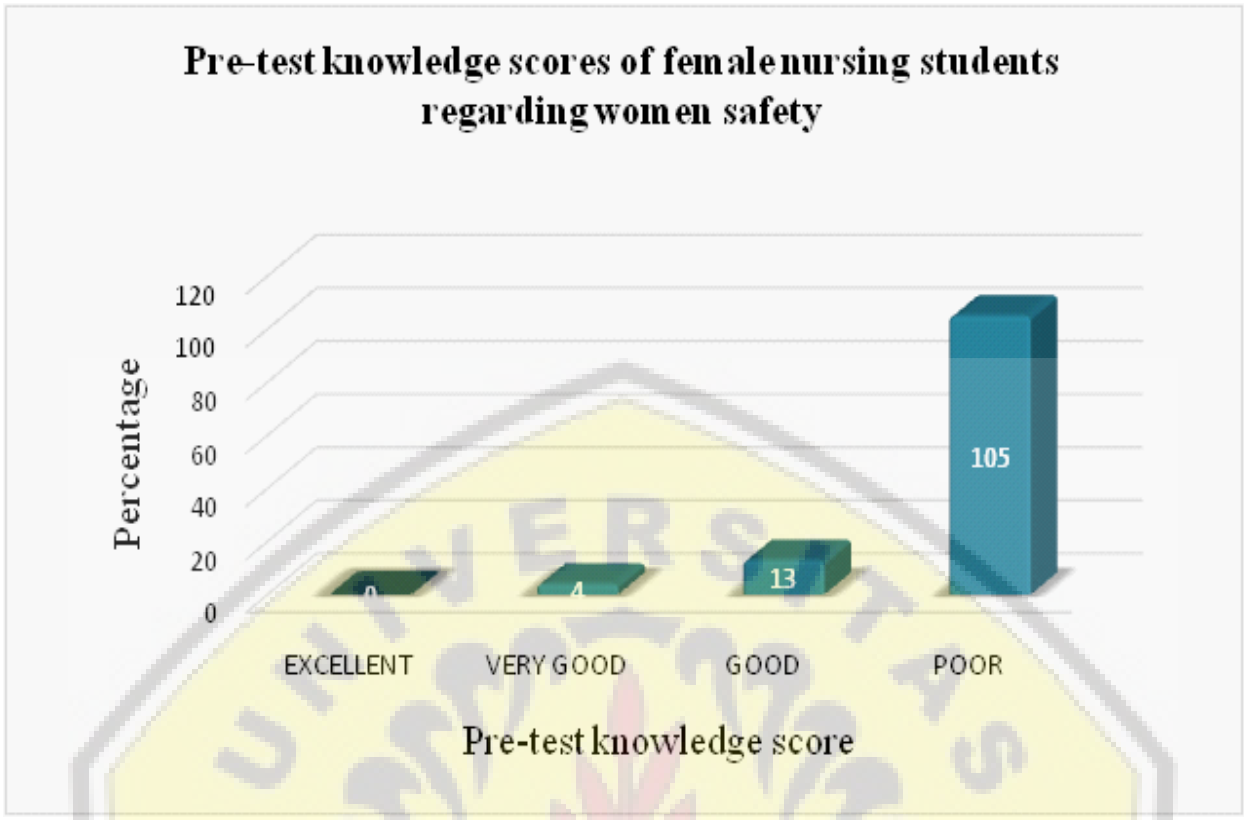

Figure 1: Distribution of samples according to the pretest knowledge scores regarding women safety.

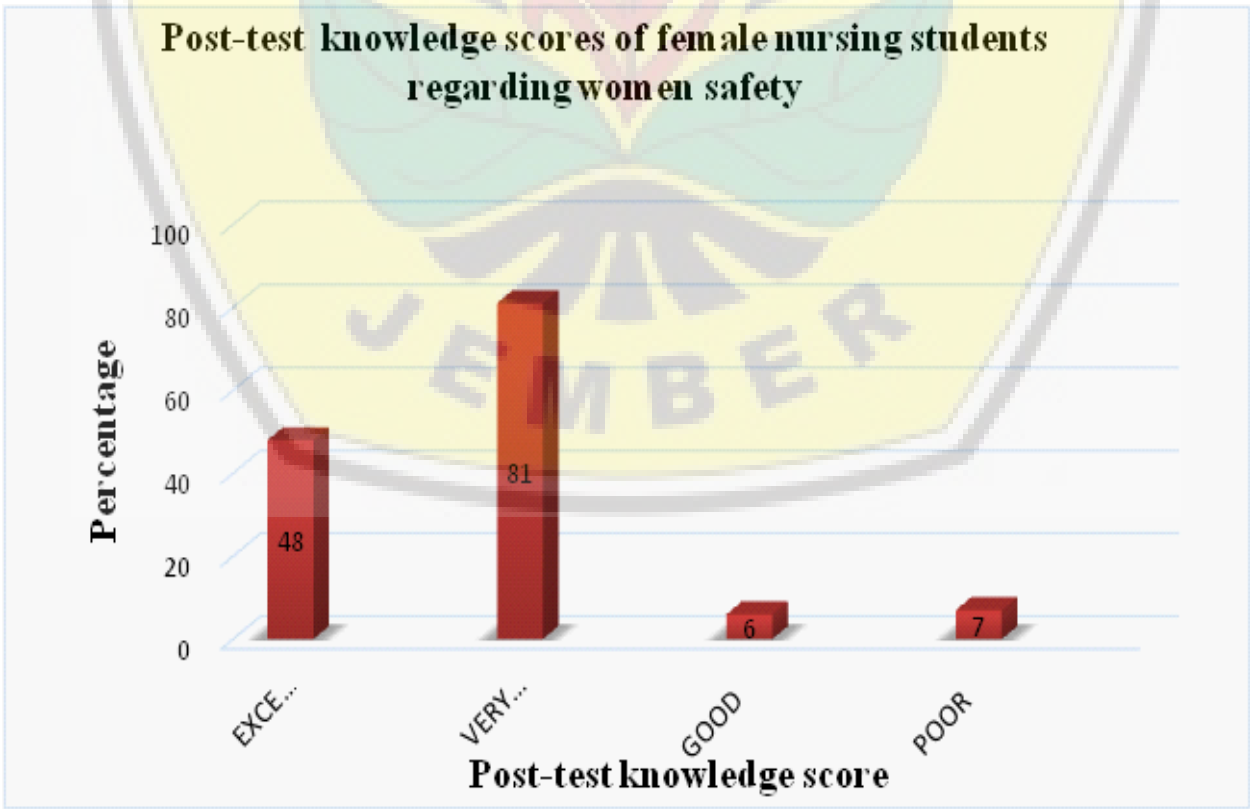

Figure 2: Distribution of samples according to the post test knowledge score of Female Nursing students

regarding women safety.

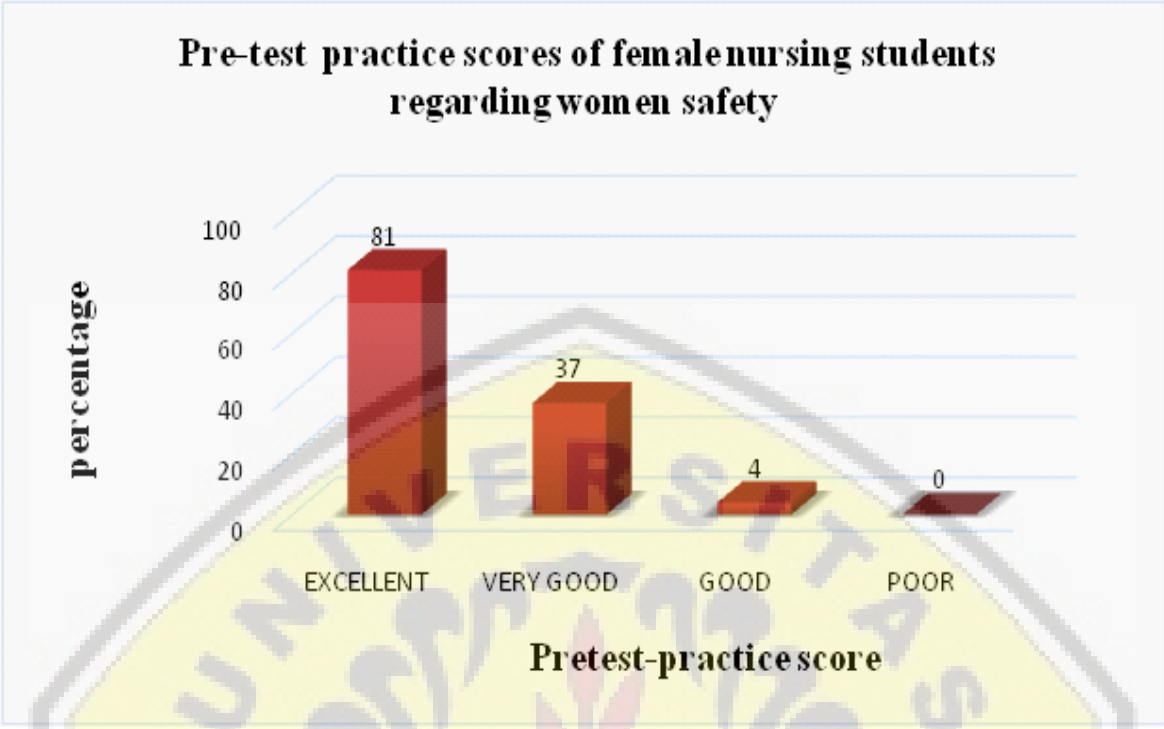

Figure 3: Distribution of samples according to the pre-test practice score of female nursing students regarding women safety.

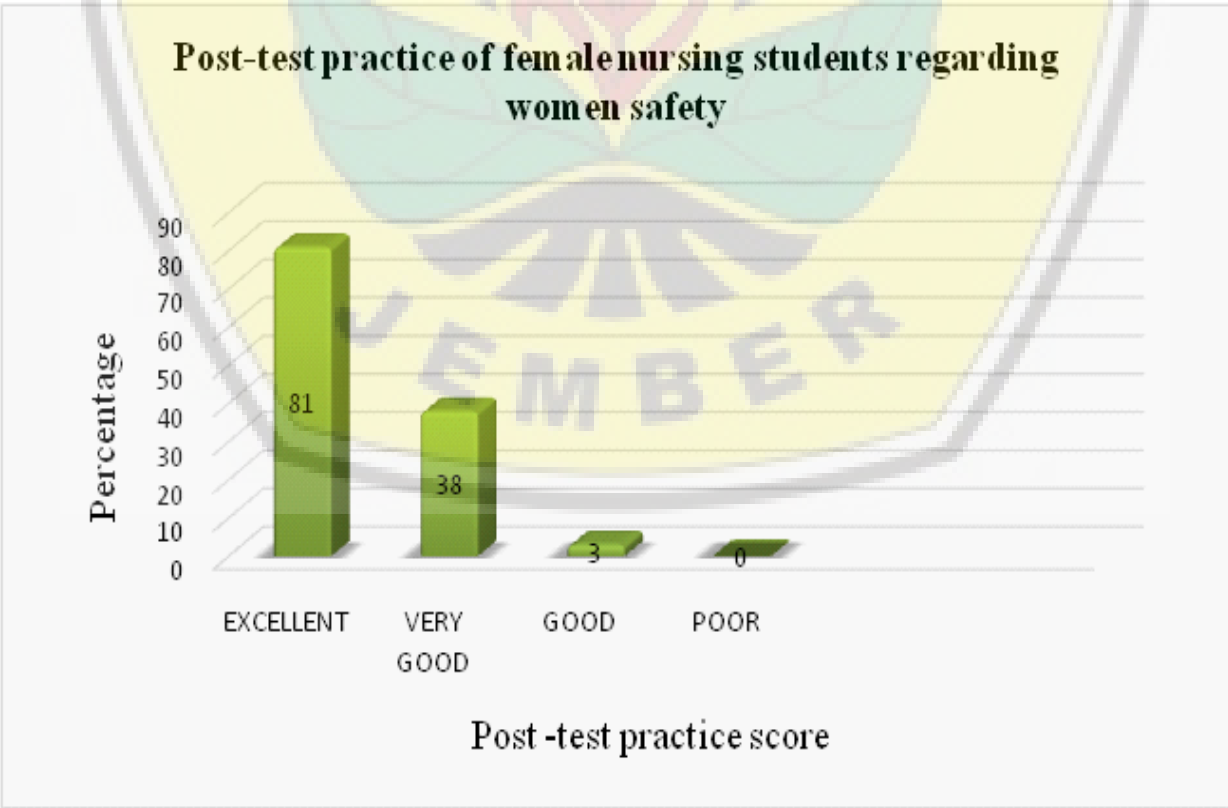

Figure 4: Distribution of samples according to the post test practice score regarding women safety.

Hypothesis-$_{02}$: The mean post-test practice score is higher than the mean pre-test practice score regarding women safety among female nursing students.

Mean post-test practice score of the female nursing students regarding women safety is 15.43, mean pre-test practice score of the female nursing students regarding women safety is 15.38. Though there is not much difference between the pre-test and post-test practice but the mean post-test practice score is significantly higher than their mean pre-test practice scores (15.38). In order to find out the significant difference between the mean score of pre and post-test practice score of the female nursing students regarding women safety paired 't' test was computed. The calculated value is higher than the table value (t-test value 0.17), the null hypothesis was rejected and the research hypothesis was accepted. Hence the researcher concluded that change of practice is not by chance but by structured teaching programme on women safety.

Association between the pre- test knowledge and practice scores of female nursing students regarding women safety and demographic variables

To identify the association between the pre-test knowledge scores on female Nursing students and the selected demographic variables. The following null hypothesis was stated

Table 1: Association between the pre- test knowledge score of female nursing students regarding women safety with the demographic variables

Demographic Variable	Frequency Numbers	Excellent	Very good	Good	Poor	Fisher's exact test

Hypothesis-$_{03}$: There will be no significant association between the pre-test knowledge scores of female Nursing student's knowledge and selected demographic variables.

Recommendations:

- A comparative study can be done between nursing colleges related to women safety.
- A similar study can be conducted with large samples.
- Study can be done using the different method of teaching.
- Further studies can be conducted on knowledge and factors influence non – compliance of optional among the female nursing students.

Conclusion

The structured teaching programme through charts and PowerPoint presentation found to be effective in improving the knowledge and practice among female nursing students related to women safety. Through this study, researchers have come to the statement of conclusion that before the structured teaching programme the female nursing students had poor knowledge,but a

good Practice related to women safety. The raised post test score gained from the structured teaching programme suggested, effective in upgrading their knowledge about women safety and should be included in the academic curriculum of every Schools, Colleges or Universities which will help to increase the knowledge about women safety among the girl's students of our society and which will give confidence to them about how to be safe and secure, also it can help us to reduce the criminal offenses towards the girls or women's in the society or in the country.

Ethical Clearance:

1. The study proposal was sanctioned by the Symbiosis college of nursing ethical committee
2. Permission was obtained from the director of the college of nursing
3. Study was explained to participants and informed consent was taken from the participants
4. Confidentiality of data collected was maintained

Source of Funding: Self.

Conflict of Interest: There is a genuine need for the awareness and to provide a good knowledge and practices regarding women safety. In a recent decade woman or a girl of any age are unsafe and at risk for harassment and violence at any time. Researcher must be able to provide a good knowledge and practices of safety for women in every schools, colleges or Universities.

An Assessment on Quality of Life Among Peri and Post-Menopausal Women in Semi Urban Area of Tamil Nadu: A Community based Cross-Sectional Study

K. Mirudhubashini[1], Nisha B.[2], Alice Matilda Mendez[2], Timsi Jain[2]

[1]3 rd year MBBS, Saveetha Medical College & Hospital, Thandalam, Tamil Nadu, [2]Assistant Professor, [3]Professor & Head, Department of Community Medicine, Saveetha Medical College & Hospital, Thandalam, Tamil Nadu

Abstract

Introduction: Menopause is the normal physiological process occurring between 45-55 years of age. Many deviations are developed during this phase in vasomotor, physical, psychosocial and sexual system of body which hampers quality of life. Therefore, this study was conducted to assess the menopausal related symptoms among peri and post-menopausal women and their impact on quality of life and to establish association between sociodemographic variables with quality of life of peri and post-menopausal women

Methodology: This is a community based cross-sectional study, which was conducted in a semi urban area, Sriperumbudur, Tamil Nadu, India for 6 months period. A total 250 women of 40 – 60 years were enrolled using multistage random sampling. MENQOL questionnaire (4 domains) was used. Data was analysed using t test, multivariate linear regression and correlation.

Results: The study group consists of 127(50.8%) women in peri menopausal group, 41(16.4%) in early post-menopausal group and 82(32.8%) in late post-menopausal group. Among 250, 105(42%) of the women's quality of life was affected. Pain in musculoskeletal system was commonest (75.61%) symptom. Age and menopausal status of women was significantly (p value <0.05) associated with all domains and total scores of QOL except vasomotor. BMI was significantly correlated with vasomotor domain.

Conclusion: The menopausal symptoms are affecting the quality of life of peri and post-menopausal women. Due to the lack of awareness majority of women do not seek medical treatment. Therefore, heavy campaigns on large scale need to be conducted to educate women and enable them to recognize the symptoms early.

Keywords: *Peri-menopause, MENQOL, early and late menopause, community-based, semi-urban area, quality of life.*

Introduction

Menopause is a normal physiological process in every women's life. It usually occurs between 45-55 years of age. It is defined as 12 months of amenorrhea after the last menstrual cycle. This process is the result of complete or partial absence of oestrogen release from the ovaries as well as depletion of ovarian follicles[1]. It marks the end of women's fertility.

India has a large population which has already crossed a mark of one billion with 71 million people over 60 years of age and the number of menopausal women about 43 million according to the third consensus meeting of Indian Menopause Society 2008. It has been estimated that the menopausal population in India will be 103 millionby the year 2026[2].

During the menopausal period women experiences many symptoms including hot flushes,night sweats,sleep and mood disorders, impaired memory, lack of concen tration,nervousness,depression, insomnia because of fluctuation in oestrogen levels[3]. There are also some serious medical conditions related to menopause like osteoporosis caused due to the loss of bone tissue and risk of heart disease increases due to age related factors like increase in weight,blood pressure and cholesterol levels[4]. The duration, severity and impact of the menopausal symptoms vary from person to person and population to population[3]. Some women have severe menopausal symptoms that greatly affect their personal and social functioning and quality of life[4].

Public health systems are over burdened with problems of women of child bearing age, adolescent and infectious diseases. As a result of which, it hardly addresses the specific health problems of older women and they are often neglected. Factors like lack of awareness, poverty and gender bias prevent them from seeking medical help appropriately [5].

In India, there are many studies which associated relationship between quality of life and menopausal symptomsamong rural and urban women[6,7, 8]. But there are only, few studies which has portrayed quality of life of perimenopausal women[4,6]. Also, there is a huge lacuna of information of these women in semi urban areas. With this background, this study is being carried out in semi-urban area of Tamil Nadu to assess the menopausal related symptoms among peri and post-menopausal women and their impact on quality of life and to establish association between sociodemographic variableswith quality of life of peri and post-menopausal women

Methodology

This is a community based cross-sectional study, which was conductedin asemi urban area, Sriperumbudur, Tamil Nadu from January 2019 to June 2019, after obtaining ethical clearance from the institutional ethical board. The study population comprised of peri and post-menopausal women of age group 40 to 60 years.

Peri menopause or menopause transition begins is defined by the World Health Organisation and the North American Menopause Society as the two to eight years preceding menopause and one year following final menses[9]. Post menopause is defined as the period after 12 consecutive months of amenorrhea in the absence of other pathological or physiological causes[9].

Sample size required in estimating proportion (prevalence)was calculated with anticipated population proportion (p) as 37% [4] with 95% confidence interval and at 5% significance level including 10% non-responsive cases, sample size derived to be 279. Multi stage sampling (2stages) method was used to enrol the study subjects.

- **In stage 1 – Selection of Polling Booths:** According to Census of India, Sriperumbudur Town Panchayat is divided into 15 wards. It covers a total population of24,864 in which 12753 and 12,111 of males and females respectively [10]. According to Election Commission of India, there are totally 12 polling booths in this area [11]. Out of these, 3 polling booths were chosen by simple random sampling method using lottery method.
- **In stage 2 – Selection of study population from polling booths:** A complete list of all people above 18 years of age was collected from the voters list [11] of selected 3 polling booths. Women aged between 40 to 60 were shortlisted from the list. After which 85 women from each polling booth were selected by simple random sampling technique using computer generated random numbers. Women who gave consent and not taking any hormonal replacement therapy were included in the study.

The data was collected using pretested structured questionnaire which includes socio-demographic details, menopausal status and MENQOL[4,7] (Menopause Specific Quality of Life questionnaire). MENQOL comprises a total of 29 questions {Four domains-Vasomotor (3 questions), Psychology (7 questions), Physical (16 questions), Sexual (3 questions)}. The responses to the questions was adopted to a 2-point scale consisting of Yes and No options from a 6-point severity scoring pattern in the original version considering the difficulty to answer on the 6-point scale due to low level of education of the respondents[13]. Each 'Yes' answer carried 1 score whereas 'no' answer was considered 0 score. Total scores for each domain and also cumulative score of all domains were calculated. The subjects were then divided into three groups according to their age and menopausal status as perimenopausal (above 40 years and not attained menopause), early (attained menopause less than or equal to 5 years) and post-menopausal women (attained menopause greater than 5 years) [3].

This data was entered in MSExcel sheet and analysis was done using SPPS 21 version software. The descriptive statistics were expressed as frequencies, percentages. Also, Means and standard deviation was used to depict scores of MENQOL. Analytical statistics like t test was used to ascertain association between sociodemographic variables and quality of life scores and multivariate analysis via linear regression was also used. Correlation tests were performed for quantitative variables like BMI, age and per-capita income.p value of <0.05 was considered statistically significant.

Result

The study group consists of 250 women of which 127(50.8%) were in peri menopausal group, 41(16.4%) in early post-menopausal group and 82(32.8%) in late post-menopausal group. The mean age of the study participants was 50.18 (SD = 7.182), similarly for BMI, mean was 24.32 (SD = 3.084) and mean per capita income was 7319 (SD = 5218.6). According to educational status substantial amount of them were illiterate (33[13.2%]), 36(14.4%) of them had less than 5th grade of schooling. Most of them were homemakers (89.2%) out of 250 participants, only meagre were working.

Mean score and standard deviation of total scores of peri-menopausal, early and post-menopausal women were [Mean (6.95), SD (5.05)], [Mean (9.41), SD (4.3)] and [Mean (8.81), SD (4.42)] respectively. Among 250, 105(42%) of the women's quality of life was affected i.e., perimenopausal women 54 (42.51%). similarly, for early and late menopausal women shown in [Figure 1].

The most common symptom in peri menopausal group is aches in nape of neck or head (54.33%) whereas, severe pain in musculoskeletal system was common among early (75.61%) and late post-menopausal women (81.71%) and distribution of menopausal symptoms of sexual domain only perimenopausal women's approximately 20% was affected. In other domains, late menopausal women had symptoms of poor health, than the other group people. The sociodemographic variables of the study participants were associated with scores of quality of life in all domains of MENQOL using t test, age of women was significantly (p value <0.05) associated with all domains and total scores of QOL except vasomotor domain whereas BMI of the participants was only significant with vasomotor domain. Using one-way ANNOVA, menopausal status of women (peri, early and late) was significantly associated with quality of life scores except vasomotor domain [Table 1].

The scores of all the four QOL domains were correlated with quantitative variables like age, BMI and percapita income. Age was significantly correlated with all domains; BMI was significantly correlated with only vasomotor domain and percapita income with physical and psychosocial domain.

Multivariate analysis using linear regression was done with various QOL domains as dependent variables. Age (>50 years) was significantly (p value <0.05) associated with psychosocial, physical, sexual and total QOL scores. BMI (>24kg/m2) retained significance with vasomotor domain, Married women had significant association with sexual domain scores.

Discussion

Life expectancy of women in India has been considerably increased to 69.6 years, therefore women are expected to spend almost a big part of lifetime in and around their menopausal phase[12]. This transitional phase that every woman will go through will encounter poor quality of life, if not intervened. Consequently, maintaining optimum quality of life among them is our priority. Hence quality of life of menopausal women was studied using MENQOL questionnaire. MENQOL was developed in 1996 and it's been applied in many studies in India[4,7].

As regards to the socio-demographic profile of the women, mean age was found to be 50.18 years (SD = 7.18) in this study as compared to study conducted by Nabarunkarmakar et al poomalar & Arunossalame in puducherry the mean age of menopause was found to be 45.93 SD=8.37 years [4], also a study conducted in Minia, Egypt by Nashwankamal and Amany E. Sudham the mean age of menopause is 48.9 SD=4 years[13]. About 1/3 rd of the women had low education level (<5th std), some of them were illiterate in our study which attributed to poor understanding of 6 point Likert scale of MENQOL and also reflected women's cooperation during conduction of the study whereas a study conducted in rural area of West Bengal [6,7] had more than half of illiterate women.

With respect to the frequencies of menopausal symptoms, In a study conducted among Qatari women by AbdulbariBener & Anasfalah the vasomotor (71%) and sexual symptoms (66%) were more prominent in perimenopausal women than early and late postmenopausal women [14], whereas, in the current study vasomotor symptoms is more likely present in late postmenopausal group but sexual discomfort was more in perimenopausal women. In a study conducted by Poomalar and Bupathyarounassalam in Puducherry showed that psychosocial symptoms (93.2%) were more prominent among the late postmenopausal group[4], similar results were also found in the current study.

Results of the current study revealed that, there was a significant association of age of women with quality

of life scores, this could be that as the age increases the severity of symptoms also increases leading to poor quality of life (Table 1), comparable findings were found by Mohamed HA et al [3]and by a study conducted in West Bengal[6,7]. Whereas, BMI was significantly associated with vasomotor domain stating that as the BMI increases vasomotor symptoms tends to increase. Menopausal status was significantly associated with MENQOL scores;however, studies did not find a relationship between the QOL and menopausal status of women. A study done in Minia, Egypt[13]states that higher educated women, working women had significant relationship with QOL scores whereas in our study education was significant only with sexual domain of QOL. Occupation variable in our study had no association affirming that 3/4th of the women were homemakers. Similar findings were found in studies conducted in Indian set up [8,15].

The limitation in our study are, all the participants were selected from one semi-urban area randomly, so the results cannot be generalized to entire population. Natural ageing process is a potential confounder which was not eliminated since it was a cross-sectional study. The chance of recall bias could not be ruled out as the women were providing retrospective information.

Conclusion

It is evident from the results that the menopausal symptoms are affecting the quality of life of peri and post-menopausal women. Age, BMI, Marital status and education are some of the factors which affects quality of life scores. Due to the lack of awareness majority of women do not seek medical treatment for menopausal symptoms affecting quality of life. Therefore, heavy campaigns on large scale need to be conducted to educate women and enable them to recognise the symptoms early, to seek timely treatment for the same to improve their quality of life.

Combination of Naturopathy and Yoga on VO2 Max among Hypertensive Patient

K. Alaguraja[1], P. Yoga[2]

[1]Research Scholar, [2]Assistant Professor, Alagappa University College of Physical Education, Alagappa University, Karaikudi, Tamil Nadu, India

Abstract

The purpose of the present study was to investigate the combination of naturopathy and yoga on vo2 max among hypertensive patient. To achieve the purpose of the study thirty hypertensive patient were selected from, Sivganaga District, Tamil Nadu, India during the year 2019. The selected patient were divided into two equal groups consists of 15 patient each namely experimental group and control group. The experimental group underwent acombined naturopathy and yoga programme for six weeks. The control group was not taking part in any training during the course of the study. Vo2 max was taken as criterion variable in this study. The selected subjects were tested on Vo2 max was measured through Cooper's 12 Minutes Run or Walk Test (stop watch and heart rate monitor). Pre-test was taken before the training period and post-test was measured immediately after the six weeks training period. Statistical technique 't' ratio was used to analyse the means of the pre-test and post test data of experimental group and control group. The results revealed that there was a significant difference found on the criterion variable. The difference was found due tocombined naturopathy and yoga given to the experimental group on VO2 max when compared to control group.

Keywords: *Combined naturopathy and yoga, VO2 max and 't' ratio.*

Introduction

According to Vrinte[1] Yoga is a methodical effort towards self-perfection by the development of the potentialities latent in the individual person. It is a process by which the limitations and imperfections can be washed away resulting in a super human in race. Alaguraja and Yoga[2] Yoga is universally benefiting all people of all ages. The study of Yoga is fascinating to those with a philosophical mind and is defined as the silencing of the mind's activities which lead to complete realization of the intrinsic nature of the Supreme Being. The science of Yoga Nidra is based on the receptivity of consciousness Yoga, et. al[3]. In Stance of World Health Organization (WHO) Obesity is a medical condition in which excess body fat has accumulated to the extent that it may have a negative effect on health, leading to reduced life expectancy and/or increased health problems.

Today's there is an escalating emphasis on appearing smarter, feeling better and living longer. In order to achieve these ideals as, scientific proof tells us that one of the keys is high fitness. On the contrary, acquiring these ideals is a challenge because today physical activity is less a part of our daily livestyle. Kerr[4] Training is not a recent discovery. In ancient times, people systematically trained for military and Olympic endeavors. Today athletes prepare themselves for a goal through training.

Alaguraja., et. al[5] Today, sports have become a part and parcel of our culture. It is being influenced and does influence all our social institutions including education, economics, arts, politics, law, mass communication and even international diplomacy. In fact its scope is awesome. Yoga is a system of exercises which helps the mind and body in order to achieve tranquility and spiritual insight. Yoga therapy that includes Aasanas and Pranayama is fast advancing as an effective measure to prevent physical and psychological disorders; by changing the human mind and body in a holistic way.[6.]

Strukic, P. J[7] VO2 max is the maximal oxygen uptake or the maximum volume of oxygen that can be utilized in one minute during maximal or exhaustive

exercise. It is measured as milliliters of oxygen used in one minute per kilogram of body weight.

Methodology

Selection of subjects: The purpose of the study was to find out the combination of naturopathy and yoga on vo2 max among hypertensive patient. To achieve this purpose of the study thirty hypertensive patients were selected as subjects at random. The age of the subjects were ranged from 25 to 40 years.

Selection of variable

Independent variable

- Combined Naturopathy and Yoga

Dependent variable

- VO2 Max

Experimental design: The selected subjects were divided into two equal groups of fifteen subjects each, such as acombined naturopathy and yoga group (Experimental Group) and control group. The experimental group underwent combined naturopathy and yoga for six days per week for six weeks. Control group, which they did not undergo any special training programme apart from their regular physical activities as per their curriculum. The following physiological variable, namely Vo2 max was selected as criterion variable. All the subjects of two groups were tested on selected criterion variable Vo2 max was measured through Cooper's 12 Minutes Run or Walk Test (stop watch and heart rate monitor) at prior to and immediately after the training programme.

Statistical Technique: The 't' test was used to analyse the significant differences, if any, difference between the groups respectively.

Level of significance: The 0.05 level of confidence was fixed to test the level of significance which was considered as an appropriate.

Analysis of the Data: The significance of the difference among the means of the experimental group was found out by pre-test. The data were analysed and dependent 't' test was used with 0.05 levels as confidence.

Table 1: Analysis of t-ratio for the Pre and Post Tests of Experimental and Control Group on VO2 Max

Variables	Group	Mean		SD		df	't' ratio
		Pre	Post	Pre	Post		
VO2 Max	Control	34.23	34.20	1.96	2.05	14	0.31
	Experimental	34.17	34.93	1.78	1.83		6.81*

*Significance at 0.05 level of confidence.

The Table-I shows that the mean values of pre-test and post-test of the control group on vo2 max were 34.23 and 34.20 respectively. The obtained 't' ratio was 0.31, since the obtained 't' ratio was less than the required table value of 2.14 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of the experimental group on vo2 max were 34.17 and 34.93 respectively. The obtained 't' ratio was 6.81* since the obtained 't' ratio was greater than the required table value of 2.14 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant. The result of the study showed that there was a significant difference between control group and experimental group in vo2 max. It may be concluded from the result of the study that experimental group improved in vo2 maxdue to six weeks of combined naturopathy and yoga .

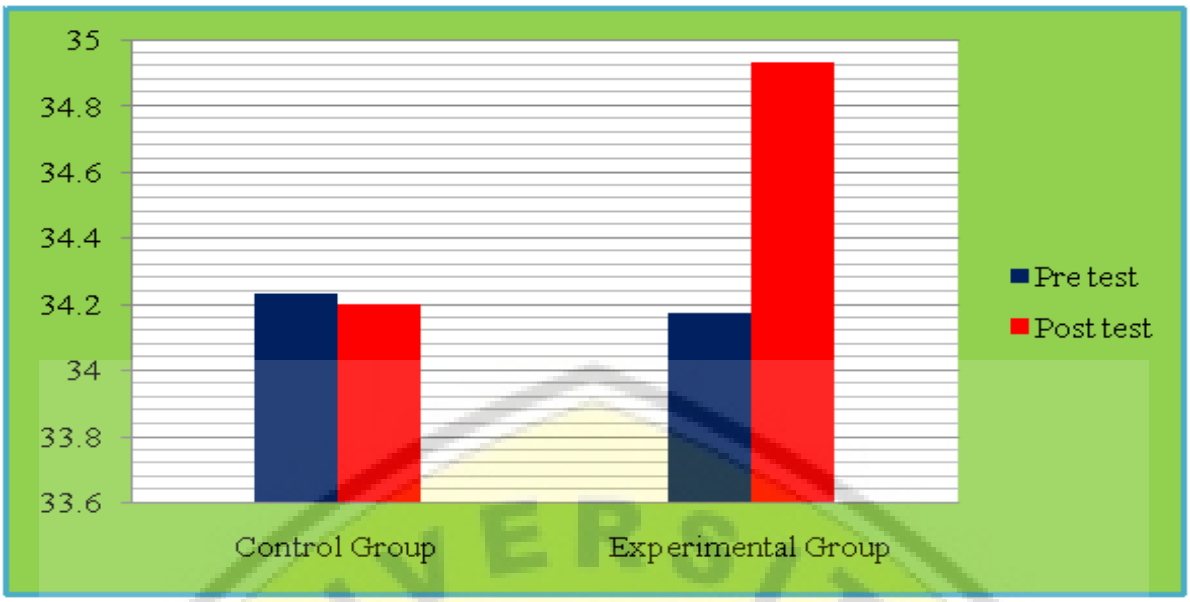

Figure 1: Bar Diagram Showing the Pre and Post Mean Values of Experimental and Control Group on vo2 Max

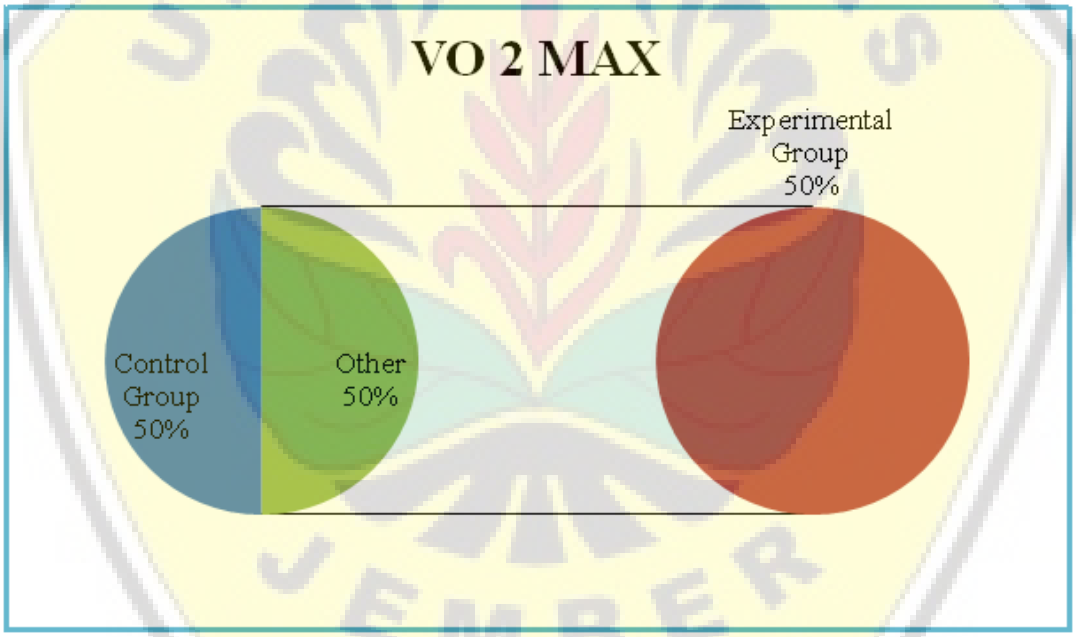

Figure 2: Comparison

Discussions on Findings

The result of the study indicates that the experimental group, namely combined naturopathy and yoga group had significantly improved the selected dependent variable namely vo2 max, when compared to the control group. It is also found that the improvement caused by combined naturopathy and yoga when compared to the control group, Alagurajaet al.[5]

Conclusion

On the basis of the results obtained the following conclusions are drawn:

1. There was a significant difference between experimental and control group on vo2 maxafter the training period.
2. There was a significant improvement in vo2 max. However the improvement was in favor of

experimental group due to six weeks of combined naturopathy and yoga.

Ethical Clearance: With respect to the above said Research Article involving human subjects for which the ethical clearance being sought, I am to state that I have gone through the "NIMHANS Ethical Guidelines……. Human Subjects" and am aware of the Helsinki Declaration of 1975, as revised in 2000 (5) rules governing the studies involving the human subjects. I am also aware that these guidelines are strictly to be followed while carrying out the above said research article involving human subjects.

Universal Health Care Coverage in India: Challenges and Opportunities

K.S. Sreejamol

Assistant Professor, Jawaharlal College of Engineering and Technology, Palakkad, Kerala

Abstract

Background: India continues to be among the countries of the world that have a high burden of diseases. The state must provide free and universal access to quality health-care services to its citizens. The present article reviews the Universal Health Coverage Scheme introduced by the Indian government to strengthen health insurance system with triple objectives of ensuring efficiency, equity and high-quality care.

Objective: The objective of the study is to analyze the significance and performance of Universal Health Coverage in India.

Method: Mixed Method research was conducted in the study to consolidate quantitative and subjective method to help assemble a more comprehensive picture of the issue addressed. The data were collected from 617 members (include both managers and consumers) from Kerala and Tamil Nadu state of India to know the level of awareness of Indian consumers.

Results: The various health program and policies in the past have not been able to achieve the desired goals and objectives.

Conclusions: These difficulties can be met by a change in outlook in health policies and programs for vulnerable population groups, rebuilding of public health units, reorientation of undergrad medical education, more accentuation on public health investigate and extensive education crusades. The Indian health system is characterized by a vast public health infrastructure which lies underutilized and a largely unregulated private market which caters to the greater need for curative treatment.

Keywords: *Risk Pooling, Universal Health Coverage, Modicare.*

Introduction

Indian health framework has enrolled significant accomplishments since independence in different key health pointers. However, much remains desired with significant weaknesses in health care organization, financing and provision of health services. of the three issues highlighted, health financing in India has been the center of significant debate. Demographic (maturing of the population), epidemiological (rising range of cost-concentrated non-transmittable ailments) and social (expanded mindfulness and desires for customers of healthcare for the mechanically propelled mind) changes in well-being have spiraled the healthcare treatment costs multifold. It has led to an impoverishment of India's poor with estimates suggesting one-fourth of all hospitalizations leading to indebtedness. Sizeable informal sector and asymmetry of information between insurer and beneficiary pose the challenge for using social and Private Health Insurance (PHI), respectively.[1] Healthcare in India is an account of insufficient resources and poor results. The venture is well beneath WHO rules in both qualitative and quantitative terms.

Objectives of the Study:

- Respondents of higher education level demonstrated a higher level of awareness of health insurance.
- It is been perceived that most of the managers or executives (Insurance Salesmen) think that consumers don't want to purchase health insurance scheme because it has no returns.

- Universal Health Insurance Scheme packages lead to public tax money being invested in private health insurance companies, rather than being put back into government funds.

Study Design: The present study is a Mixed Method research which consolidates quantitative and subjective method to help assemble a more comprehensive picture of the issue addressed. Secondary research includes the summary, collation and/or synthesis of existing research.[2]

Research Methodology: The present study is a Mixed Method research. The analysis is based on Primary data collection as well as Secondary data collected from various websites, newspapers and other necessary official records, books and magazines. Monthly closing prices have been taken for technical analysis purpose from the year 2013 to 2018. The data were collected from 617 members (include both managers and consumers) from Kerala and Tamil Nadu state of India. Statistical measures like simple moving averages, Pearson Chi-Square, have been used to find out the conclusion. Besides tables and charts are used to present and analyze data.

Efforts and Actions Related to Universal Coverage: Achieving universal healthcare requires a significant amount of investment into the health technology infrastructure. For that purpose, the government has introduced National Health Insurance Schemes. Those schemes are:

i. **Rashtiya Swasthiya Bima Yojana (RS BY):** Ministry of Labor and Employment has propelled RS BY (Rashtriya Swasthiya Bima Yojana), Government of India to give medical coverage scope to Below Poverty Line (BPL) families. The target of RS BY is to give security to BPL family units from money related liabilities emerging out of wellbeing stuns that include hospitalization. Recipients under RS BY are qualified for hospitalization scope up to Rs. 30,000/- for the more significant part of the diseases that require hospitalization.[3]

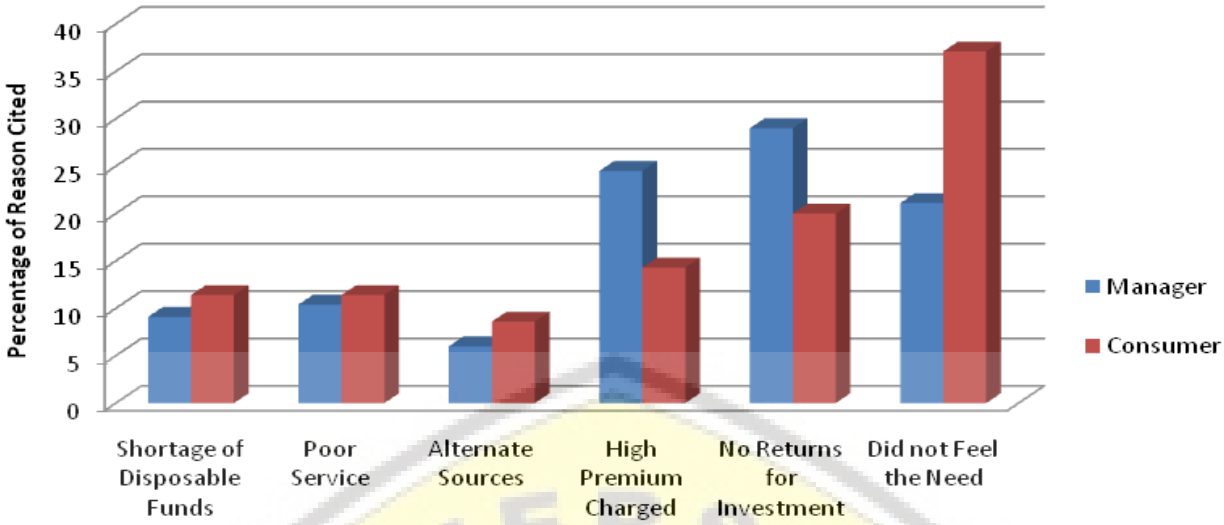
ii. **Employment State Insurance Scheme (ESIS):** Employees' State Insurance Scheme of India is a multidimensional, savings framework tailored to give financial assurance to the worker populace and their dependents secured under the scheme. Other than full restorative look after self and dependents, that is permissible from the very beginning of insurable work, the guaranteed people are additionally qualified for an assortment of trade benefits out occasions of physical trouble because of affliction, temporary or permanent disablement and so forth bringing about loss of acquiring limit, the restriction in regard of insured women, dependents of safeguarded people who die in industrial accidents or due to business damage or occupational hazard are qualified for a month to month annuity called the dependents to advantage. [4]

iii. **Central Government Health Scheme (CGHS):** The Central Government Health Scheme (CGHS) was begun under the Indian Ministry of Health and Family Welfare in 1954 with the target of providing extensive medical care facilities to the employees, pensioners of Central Government and their dependents residing in CGHS covered cities.[5]

iv. **Aam Aadmi Bima Yojana (AABY):** Aam Aadmi Bima Yojana, a Social Security Scheme for the rural landless household was launched on second October 2007. The earning member of the family or the head of the family of such a household is secured under the scheme. The Central Government and the State Government equally share the premium of Rs.200/- per person per annum. The age limit coverage of this scheme is between 18 and 59 years.[6]

v. **Universal Health Insurance Scheme (UHIS):** For enhancing the entrance of health care to low-income families, four public sector general insurance companies have been selected for implementing Universal Health Insurance Scheme. The scheme accommodates repayment of restorative costs up to Rs.30,000/- towards hospitalization floated among the whole family, demise cover because of a mischance @ Rs.25,000/- to the gaining leader of the family and remuneration because of loss of procuring of the acquiring part @ Rs.50/- every day (most extreme up to 15 days). Focusing on the BPL families; the Universal Health Insurance Scheme (UHIS) has been upgraded.

Reason for Not Taking Health Insurance Policy-Consumer vs Company: The necessary inquiries: what are the variables that shoppers consider vital while settling on the buying choice of medical coverage and why they do not purchase? Executives at times concur with what clients say while having distinctive reasons in some other. A general correlation of perception of purchasers' explanations behind these and company executives' view it is made here.



Source: Primary data

Chart 1: Perception Comparison of Managers & Consumers

From Chart 1 it is evident that around 37.1 percent respondents never felt the urgency to purchase Health Insurance whereas 29 percent of the managers think that consumers do not want to purchase health insurance scheme because it has no returns.

Test of Awareness vs Educational Qualification:

			Total Awareness Level					
			Very Low	Low	Neither High Nor Low	High	Very High	Total
Education Qualification	Less than Degree	Count	17	66	98	59	8	248
		% within Educational Qualification	6.890%	26.60%	39.50%	23.80%	3.20%	100%
		% within Total Awareness Level	65.40%	61.70%	40.30%	29.10%	21.10%	40.20%
		% of total	2.82%	10.70%	15.90%	9.60%	1.30%	40.20%

		% within Total Awareness Level	100%	100%	100%	100%	100%	100%
		% of total	4.20%	17.30%	39.40%	32.90%	6.20%	100%

Source: Primary Data

The awareness rating of respondents with various educational qualifications is analyzed for estimating the association between education group and awareness level announced.

H_0: There is no association between education and awareness level

H_A: There is a connection between education and awareness level

Table showing results of Chi-Square Tests:

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	50.933[a]	12	.000
Likelihood Ratio	53.315	12	.000
Linear-by-Linear Association	31.655	1	.000
N of Valid Cases	617		

The test was observed to be significant with ($p < 0.05$). Thus the connections clarified above are measurably significant.

It is construed that there is an association between education level and level of awareness of health insurance. Respondents of higher education level demonstrated a higher level of awareness of health insurance.

Government led actions on the financing of clinical services: Prime Minister Narendra Modi's government's ambitious plan, named "Modicare" by Indian media. Under the arrangement, the government will take care of health-care costs of up to $7,800 for 100 million low-income families and spend around $188 million to make "health and wellness" centers. Spending on nourishment for tuberculosis patients, cleanliness drives and training will likewise result in huge upgrades in public health.[7]

India is moving towards fast-tracked initiatives aimed at achieving the tenets of universal health coverage - strengthening health systems, improving access to free medicines and diagnostics and reducing catastrophic healthcare spending. The government has launched the Ayushman Bharat programme, which rests on the twin pillars of health and wellness centers and the National Health Protection Mission for 100 million families covering 500 million individuals. This plan will reach out to approximately 40 percent of the country's population who will be provided an insurance cover of Rs 500,000 per year. Apart from the rapid scale-up of diagnostics and treatment, the government has introduced supplementary nutrition for patients for the duration of treatment.[8]

Challenges and opportunities:

- **Challenges:** India has been widely criticized for having one of the world's lowest public spending on health (1.2% of GDP), but even with this minimal expenditure, it is as yet conceivable to accomplish universal health coverage (UHC). India's Ministry of Health has evaluated that taking off UHC will cost around $6.5 billion every year for a long time (2015-19). Therefore, the expense of taking off UHC is just 0.28 percent of India's GDP and well within the country's public health expenditure. UHC in a general sense implies improved access to health services and improved health outcomes. Central and state approaches in India are focused on budgetary hazard security and thinking of new health insurance packages. It is significant that these insurance packages lead to public assessment cash being put resources into private health insurance companies, as opposed to being returned to government funds, where it could be utilized to, for instance, improve the essential healthcare infrastructure and healthcare workforce in rural zones.[9]
- **Opportunities:** A high-level expert group on UHC was established by the Planning Commission of India in October 2010, with the order of building up a structure for giving effectively available and reasonable healthcare to all Indians.

  Public and private hospitals in urban areas have seen a steep rise in the adoption of technology, but these systems are disparate and use various technology systems. Consequently, patients' health information gets trapped in silos, unable to be shared with other systems and establishments due to lack of interoperability.

  The need of the hour is to ensure high data quality by introducing a secure, digital system to maintain Electronic Health Records (EHRs) in pre-defined standards. This digital, standardized platform would ensure that patients' health information is available when and where it is needed. Ultimately, this would bring a patient's total health information together to support better health care decisions and more coordinated care.

Sugessions:

i. India's government needs to assume a stewardship role. By building a compelling administrative system and steady strategies crosswise over states and the Center, workforce shortages can be survived, alongside coordinating healthcare offices over the village, town and local levels. Persistent intrigue can be kept as an essential concentration by changing such bodies as Rashtriya Swasthya Bima Yojana (RS BY) and National Rural Health Mission. (10)

ii. The private sector can help improve India's healthcare infrastructure. However, without faster accreditation, few private players will gain credibility, or raise standards, resulting in low customer satisfaction, more extended emergency clinic stays and poor administration. The National Accreditation Board for Hospitals and Healthcare Providers need to roll out incentives encouraging accreditation and make it a mandatory process.

iii. Public-private partnerships or build-operate-transfer or operations and contracting maintenance schemes can utilize private capital for provisioning healthcare services.

iv. Insurance coverage is likewise appalling in India, with just around 25% of the populace secured. In order to accomplish universal access, a coverage proportion of around 75% should be focused, with the rest of access through government installments through RS BY.

v. Social insurance plans should be taken off at scale, with the government sending a more prominent offer of healthcare funds for RS BY.

vi. Some smart targets need to be prioritized to achieve UHC in India. They are:

- The government should focus on reducing child under nutrition and chronic diseases.
- The number of malaria infections and tuberculosis deaths should be reduced.
- The focus should be provided to reduce the newborn mortality rate.
- Childhood immunizations should be increased.
- Improving access to family planning.

Discussion

It is critical because the twin objectives of UHC: that individuals and populaces get the health services they require, without confronting budgetary hardship. WHO assesses that about 150 million individuals around the globe experience the ill effects of out-of-pocket expenditure on health services, while 100 million individuals are pushed underneath the neediness line.

There is no one-size-fits-all approach to deal with accomplishing UHC. T Maturing populaces and the blossoming weight of non-communicable diseases present exceptional difficulties that will require all nations to discover creative approaches to reshape their health systems.(11) On the first challenge, two promising methodologies rise: utilizing general incomes to cover the casual sector completely or utilizing a combination of tax subsidies, non-financial incentives and contributory requirements.

The previous can create quick outcomes, yet puts weight on government spending plans and may incite casualness, while the last will require a robust managerial mandate and systems to follow the capacity-to-pay. As for advantage bundles, we find considerable variation in the nature and meticulousness of procedures necessary the selection and refreshing of the services included. Likewise, when all is said in done, bundles do not yet concentrate adequately on non-communicable diseases (NCDs) and related preventive outpatient care. At last, there are significant variations and imbalances in the supply-side preparation, as far as accessibility of infrastructure, equipment, essential drugs and staffing, to deliver on the promises of UHC. Health specialist skills are likewise a constraint.(12)

Conclusion

The objective of Universal Health Coverage is to guarantee that all individuals acquire the health services they need without languishing money related hardship while paying over them. Thus institutionalization of tax-funded Universal Health Insurance Scheme (UHIS), with the complementary role of private health care (PHI) is strongly recommended. State Health Insurance (SHI) schemes should be merged with UHIS. Benefits package of this scheme should include preventive and in-patient curative care to begin with and gradually include out-patient care. State-specific priorities should

be incorporated into the benefits package. Application of such an insurance system besides being essential to the goals of an effective health system provides an opportunity to regulate the private market, negotiate costs and plan health services efficiently. Purchaser-provider split provides an opportunity to strengthen public sector by allowing providers to compete. It requires a reliable, efficient, well-run health system; a system for financing health services; access to essential medicines and technologies; and a sufficient capacity of well-trained, motivated health workers who can spread the awareness regarding the importance of health Insurance scheme among the citizen of India.

A Study on Risk Factors Associated with Central Serous Chorioretinopathy and Relation Between Risk Factors and Visual Recovery

Kali Shankar Das[1], Asim Kumar Ghosh [2], Lakshmi Kanta Mondal[2], Supartha Barua[3]

[1]Assistant Professor, Department of Ophthalmology. Nil Ratan Sircar Medical College, [2]Professor, Regional Institute of Ophthalmology, [3]Assistant Professor, Department of Psychiatry, Institute of Psychiatry-A Centre of Excellence, I.P.G. M.E. & R. Kolkata, West Bengal, India

Abstract

Central serous chorioretinopathy (CSR) sudden onset of uniocular and binoucular diminished vision associated with a positive relative scotoma, metamorphopsia and hyperopic shift. Pathophysiology of central serous chorioretinopathy is highly controversial, various risk factors are proposed. The study aims to determine various risk factors associated with CSR as compared to age and sex matched controlled group. Results show male predominance (5.5 : 1), 90% population returned to normal vision after 3 months, though few patients (10%) did not regain good vision. Stress, steroid intake,recent life events, tobacco use, antihistaminics use and development of this condition predispose to this condition. No statistically significant risk factor was found between patients with poor visual outcome and risk factors present in them.

Keywords: *CSR, visual recovery post CSR, risk factors with CSR.*

Introduction

Central serous chorioretinopathy (CSCR/CSR) is typically a sporadic, self-limited disease of young or middle-aged young males. This fairly common condition is characterized by a usually unilateral, localized detachment of the sensory retina at the macula with or without retinal pigment epithelium detachment.[1-3] The study aims to find out the risk factors and systemic findings in-patient of CSR.

Materials and Method

It is a prospective observational case control study. Patients were selected from the out patient department of the Regional Institute of Ophthalmology, Kolkata. Patients of acute, chronic and recurrent CSCR were included in the study. CSR was diagnosed on the basis of history, complete ocular examination, including direct ophthalmoscopy, +78D or +90D examination of the macula, indirect ophthalmoscopy, fundus photography, Fundus Flourescence Angiography (FFA) (if nedded).

Psychiatric evaluation was done to collect data on psychological stress included recent life events (such as death, divorce, marital, business or family strife) and any alcohol abuse were cited. Patients who were diagnosed as anxiety spectrum disorder and alcohol abuse or dependence were treated in psychiatry and ophthalmology department simultaneously.

All cases were followed 2 weekly till complete resolution of the ocular condition confirmed by the detailed ocular examination by the aforesaid method for a maximum period of 1 year.

Data Analysis: To determine if there is any relationship between visual recovery and risk factors present the cases were divided into 2 groups. Group 1 – Patients with ultimate BCVA of ≥6/12 and Group 2

– Patients with BCVA< 6/12. The risk factors present in them are calculated. Data collected are analysed by chi-square test to find out the stastistical significance. The Fisher exact test was used instead of chi-square test when the expected cell counts were 5 or fewer. Odds ratio was calculated to find out the relative risk between exposure and the disease.

Inclusion Criteria: Idiopathic Central Serous Chorioretinopathy proven by the above examinations.

Exclusion Criteria:

The exclusion criterias are as follows: Any macular abnormalities of the affected eye other than CSR such as secondary causes of CSR, trauma, optic nerve pit.

Result and Analysis

78 consecutive patients of CSCR were included in the study. The mean age of the cases was 38.93 years (Standard deviation : 6.9, median : 38 years). There were 66 males and 12 females in the CSCR group (M:F = 5.5 : 1). 61 patients had first episode of classic CSCR and 17 cases had recurrent or chronic CSCR. There were 78 age and sex matched controls.

In our study 70 (89.74%) of the 78 cases achieved good visual recovery (Visual acuity ≥ 6/12) at the end of 1 year follow up. Only 8 (10.25%) cases experienced unsatisfactory visual recovery (visual acuity< 6/12). Patients with poor visual outcome were analysed against the risk factors present in them to find out any relationship between the risk factors and unsatisfactory visual recovery.

In our study systemic steroid use was present in 11 (14.10%) of 78 cases whereas it was present in 2 (2.56%) of the controls. Fisher exact test was performed on these data and the P value was seen to be 0.0173 (< 0.05).

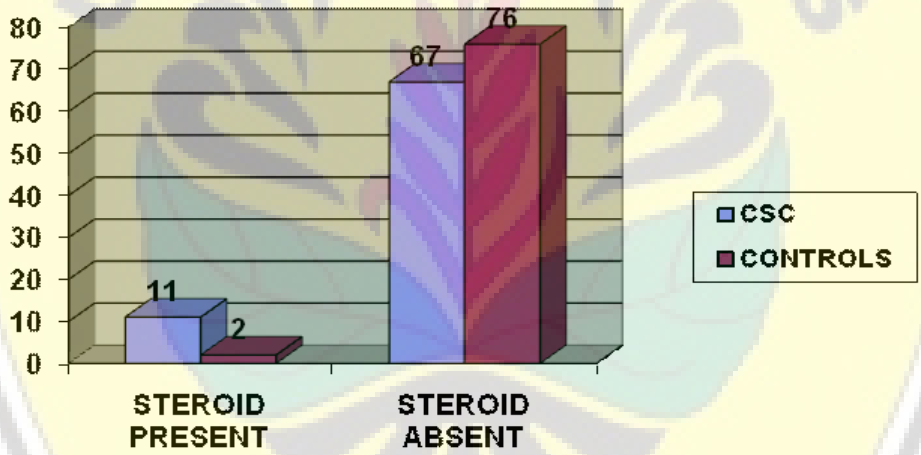

Figure 1: Bar diagram depicting the use of steroid in cases and controls

Table 1: Presence of stress among cases and controls

Stress	CSC	Controls
Present	20	10
Absent	58	68
Total	**78**	**78**

In our study self reported or psychiatrist elicited psychological stress was present in 20 (25.64%) CSR patients and 10 (12.8%) controls. Chi-square test was performed on these data r =4.127 was P = 0.0422 (< 0.05).

In our study we have found 14 (17.9%) of the 78 patients have history of smoking whereas 5 (6.41%) of the 78 controls are found to be smokers. As alcohol intake may be a confounding factor so we have excluded patients with history of both alcohol and smoking intake. Fishers exact test was performed and two tailed p value was found to be 0.0479 (<0.05).

Table 2: Presence of smoking among cases and controls

Smoking	CSC	Controls
Present	14	5
Absent	64	70
Total	**78**	**78**

Odds ratio = 3.19, P value < 0.05

In our study we have found 5 (6.4%) of the 78 patients with CSR has history of alcohol intake whereas 2 (2.56%) of the 78 controls are found to be alcoholic. As smoking may be a confounding factor so we have excluded patients with history of both alcohol and smoking intake. Odds ratio was calculated from the above data and was found to be 2.60. Fishers exact test was performed and two tailed p value was found to be 0.4423 showing that the difference is not statistically significant.

Table 3: Antihistaminics use among cases and controls

Antihistaminics	CSCR	Controls
Present	11	3
Absent	67	75
Total	**78**	**78**

Odds ratio = 4.104, P value 0.0466(< 0.05).

Among study population, 8 cases with poor visual recovery steroid use was found in 3 (37.5%) of them. All 3 of these patients showed macular pigment epithelial atropic changes. On the other hand 3 (27.27%) cases of the total 11 cases with systemic steroid use experienced poor visual recovery. These findings were plotted in the 2 × 2 contingency table and P value calculated. The two sided P value was 0.079 which is less than 0.05 showing that there is no statistically significant correlation between steroid use and final visual acuity.

In our study stress was identified as a risk factor in 5 (62.55%) cases with poor visual recovery. So, on the other hand 5 (20%) of the 25 cases with positive stress has poor visual recovery. Fisher's exact test was performed on these data and P value was found to be 0.24, showing no statistical significance.

Discussion

Idiopathic CSR is a disorder characterized by neurosensory retinal detachment associated with retinal pigment epithelial detachment, leakage and angiographic retinal pigment epithelial and choroidal hypermeability.[1-3]

Systemic steroid use was found more (14.10%) in cases than controls (2.56%) {Odds ratio 6.23, P< 0.05}. The results matched with previous study.[4,5] In our study we have also found a statistically significant relationship between steroid use and development of CSR. Apart from this we have also found that of the total 8 patients that have unsatisfactory visual recovery 3 (37.5%) of them are steroid users. These patients also developed diffuse macular pigment epithelial atrophic changes.[6,7]

In our study psychological stress statistically significant correlation was found between recent psychological stress and development of CSR. The result is similar as previous studies.[8,9]

The possible aetiological role of adrenomedullary system associated with increased catecholamine secretion has also been proposed.[9-11] When the choroidal vessels are severely affected by the elevated blood pressure, as in acute hypertension, fibrinoid necrosis of choroidal arterioles can cause occlusion of areas of choriocapillaries, with a subsequent breakdown of the outer blood retinal barrier. These changes might lead to fluid leakage in the sub retinal pigment epithelial space and development of CSR.

In our study alcohol use or abuse was present in 5 CSC patients and 2 controls (odds ratio [OR], 2.6; P > 0.05) and smoking was present in 14 CSC patients and 5 controls (OR = 3.19; P < 0.05). So a statistically significant relationship was found between smoking and development of CSR. Increased substance abuse involving alcohol and tobacco among CSC patients may also represent a dysfunctional behavioral adaptation to psychological stress.

A positive relationship exists between different various types of stress and the rate of smoking.[12,13] Both human and primate studies suggest that stress increases alcohol consumption.[14] Both tobacco and alcohol use can directly contribute to CSC pathogenesis. Nicotine exposure and chronic alcohol feeding might impair nitric oxide induced vascular dilatation.[15-17] Both alcohol[18] and nicotine[19] under some conditions potentiate norepinephrine-induced vasoconstriction, a potential mechanism previously considered for corticosteroid related CSC[20]. Alcohol consumption might also, under certain conditions, stimulate plasma catecholamines and corticosteroid release[21].

We found antihistaminics use (odds ratio = 4.104, P < 0.05) to be a significant risk factor for patients with CSR. Because antihistaminics are commonly used for the treatment of vasomotor and seasonal allergic rhinitis, a potential relationship between CSR and these conditions require further investigations.

In our study 3 (37.5%)) of the 8 patients with poor

visual recovery are steroid users whereas in the rest 5 (62.5%) stress was identified as a risk factor. No significant relationship could be elicited between the effect of risk factors and final visual outcome. In all the 8 patients significant macular pigment epithelial atrophic changes were seen. So, in a small number of cases, the visual outcome may not be as favorable. Levine and associates[22] suggest that the visual prognosis of CSC patients is not as benign as previously thought. In a long-term study of 14 eyes by FFA, these authors concluded that CSC may be a diffuse, progressive RPE disorder. Non-leaking RPE defects were present inside the previously detached areas in all cases and were also present outside these areas in 43 percent of cases. In the fellow eye, 42 percent had new RPE window defects. Yannuzzi and coworkers[7] have also suggested that for a subset of CSC patients, the visual prognosis may not be so benign. In their series of a subset of 32 CSC eyes with peripheral RPE atrophic tracts, 25 percent of patients had a final visual acuity of 20/200 or worse. Loo RH et al, 2002, in there study showed that 96.0% of central serous chorioretinopathy patients with visual acuity < 6/12 had macular retinal pigment epithelium atrophy. [23]

It is evident in the subset of patients, poor visual recovery may also be the consequence of chronic manifestations of the disease. So, it can be speculated that the underling pathophysiological process is ongoing in these patients. As stress is definitely a risk factor for development of CSR, probably these patients fail to cope with it, resulting in persistent high levels of serum corticosteroids with or without catecholamines with resultant damage to the RPE layer. A larger study is needed to bring out any relationship between the risk factors and final visual outcome.

Conclusion

In our study of 78 patients with CSR with age and sex matched 78 controls, to find out the systemic risk factors for development of the disease and also to examine the relationship between the risk factors and final visual outcome the following conclusions can be drawn from it.

1. A significant association was found between developments of CSR and use of systemic steroids, stress, hypertension, tobacco use, antihistaminics use.
2. No, statistically significant relationship was found between alcohol use or abuse and development of CSR.
3. No statistical significant risk factor was found between patients with poor visual outcome and risk factors present in them.

CSR remains a unique ophthalmic condition in which a definitelink between psychological profile and end organ alterationsmay one day be made. Whether modulating these risk factors will affect the course or severity of CSR requires further prospective investigation.

Assimilating Novel Perspectives of Complimentary Feeding among Mothers of Infants

Kogila P.[1], Sujatha Sridharan[2], Rajalakshmi[3]

[1]Research Scholar, Chettinad College of Nursing, [2]Professor, Department of Pediatrics, Chettinad Hospital and Research Institute, [3]Professor, Child Health Nursing, Chettinad Academy of Research and Education, Tamil Nadu, India

Abstract

Complementary feeding is a process of gradually introducing semi-liquid to semi-solid foods along with breast milk at the completion of 6 months. WHO: 3 key determinants to reduce infant malnutrition are Adequate & appropriate feeding, Health care and maternal education, Environmental health[6,7]. The objectives were to assess the demographic variables of infants and mothers of infants, to assess the pre and posttest knowledge among mothers of infants. Method and materials: Quantitative evaluative approach, pretest posttest control group design were used. An extensive review of literature and guidance by experts formed the foundation to the development of the study and study tool. The data collection tool was validated and reliability was established Simple Random sampling technique with the sample of 500 mothers of infant were included. Obtained written consent from each participant before collecting the data and confidentiality of data were maintained. The collected data was tabulated and analyzed by using descriptive and inferential statistics. There was no significant association between the selected demographic variables. Study group mean and SD 21.6±3.22, SE-0.83, Control group mean and SD 16.2.6±2.01, SE-0.52, t value-5.4, Cohen's 'd' 1.96, Effect size 0.7. Additional counseling session and health Education was arranged for the mothers who are having Moderate and inadequate knowledge on Complementary feeding[1].

Keywords: *Novel perspectives, pediatrics, complementary feeding, mothers of infants.*

Introduction

"Complementary feeding is the process of starting when breast milk alone is no longer sufficient to meet the nutritional requirements of an infants, it should Start at 6 months, breastfeeding should be combined with safe, age-appropriate feeding of solid, semi-solid and soft foods for at least the first year of life"[2,3,4].

The UN estimates that 2.1 million Indian children die before reaching the age of 5 every year–four every minute-mostly from preventable illnesses such as diarrhea, typhoid, malaria, measles and pneumonia. Every day, 1,000 Indian children die because of diarrhea alone[2,3 and 4].

- UNICEF worldwide statistics April 2018
  - Only two fifths of infants 0-6 months of age exclusively breastfed.
  - Only around two thirds are introduced to solid foods in a timely manner[1,5].
- Global Infant mortality rate: 13 deaths/1000 live births[2,6].

Statement of the Problem: A study to assess the level of knowledge on Complimentary feeding among mothers of infants at selected tertiary care hospital, Kancheepuram, Tamil Nadu.

Objectives:

1. To assess the demographic variables of infants and mothers of infants.
2. To assess the pre and posttest knowledge on complementary feeding among mothers of infants.
3. To find out the association between the knowledge of mothers of infant with selected demographic variables.

Operational Definition:

Level of Knowledge: It refers to the relevant information of mothers of infant regarding complementary feeding which will be evaluated through structured questionnaire, correct responses of mothers are further classified into adequate (≥76%) moderate (51-75%) and inadequate (≤50%)[7]

Complementary Feeding: It is refers to at the completion of 6 months introducing liquids, semisolid and solid foods gradually by locally available and affordable type of foods are provided to the baby along with continued breast feeding. Liquid foods such as rice water, vegetable soups and green leafy vegetables soups. Semisolid foods like thick rice flour kanji. Solid foods like well mashed cooked potato, fruits and vegetables, mashed rice etc.

Mothers of infant: Mothers who are in the age group of 21-40 years & having infant 3-12 months attending well baby clinic for infant immunization and plan to have all immunization in a Selected Tertiary Care Hospital, Kelambakkam, Kanchepuram District.

Material and Method

Research approach: Quantitative, Evaluative approach seems to be the most appropriate approach for this study.

Research design: Pretest posttest control group design was seems to be the most appropriate design for this study.

Research setting: The present study was conducted at Chettinad Hospital and Research institute in Kanchipuram district, Tamil Nadu, India.

Sample and sample size: Infant and mothers of infant between the age group of 3-12 months and who full-filled the inclusion criteria were recruited for this study. Based on the power analysis calculation Formula N= p (1- p) (Z/E)2, sample size of 500,out of which 250 infant and mothers of infant randomly assigned to study group and 250 were assigned to control group. Simple Random sampling technique was used to select the infants and mothers of infants.

Sample Criteria:

Inclusion Criteria:

The study includes infants, who are:

- aged 3 - 5 months; who are either exclusively breast feed or partially breast feed but have not started complementary feeding.
- term/appropriate to gestational age.
- age group between 3 months to 1 year.
- attending pediatric outpatient department.

The study includes mothers of infants who:

- Can read & understand Tamil/English.

Exclusion Criteria:

The study excludes infants who are:

- Critically ill.
- having mal absorption syndrome.
- Known genetic anomaly, neurological disorder.

The study excludes mothers of infants who are:

- having adequate pretest score (≥76%)
- fails to give consent for any reason.
- sick.

Score Interpretation:

Table (1): Standardized structured questionnaire to assess the knowledge on complementary feeding.

Score	Percentage (%)	Inference
0-14	≤49%	Inadequate knowledge
15-22	50-75%	Moderately adequate Knowledge
23-30	76-100%	Adequate knowledge

Data Collection Procedure: Structured questionnaire was used to assess the data of demographic variables and the level of knowledge on complementary feeding. Data was collected for a period of 18 months. Obtained written consent from each participant before collecting the data and confidentiality of data were maintained.

Research Tool:

Part-I: Selected demographic variables of infants and mothers of infants such as age of the mother, education, occupation, source of information, age of the child, sex of the child, number of the children, order of children.

Part-II: A structured questionnaire is used in this study which includes 30 multiple choice questions with 120 items. Each correct answer carries "1" (one) mark and wrong answer carries "0" (zero) mark. The maximum score is 30 and minimum score is 0.

Analysis and Interpretation: The study shows that majority of 51% mothers belong to the category of 26-30, 30% mothers belong to the category of 20-25 & 19% of mothers belong to the category of 31-35 years. Most of them 33% were belong to the category of Primary education. Very few 26.1% were belong to Daily wages. Most of them 52% were gains information through the doctor, 44% of mother gain information through Health workers & 4% of mother gains information through the family. The study shows most of them 57.6% were female & 43.4% belong to male infants.

The study shows that majority of 59.3% of mothers of infants having adequate knowledge on immunization, 24.5% of mothers of infants having moderately adequate knowledge & 16.2% of mothers of infants having inadequate knowledge. There is no significant association between the demographic variables like occupation, age of child, sex of child and order of children and source of information with post test knowledge score.

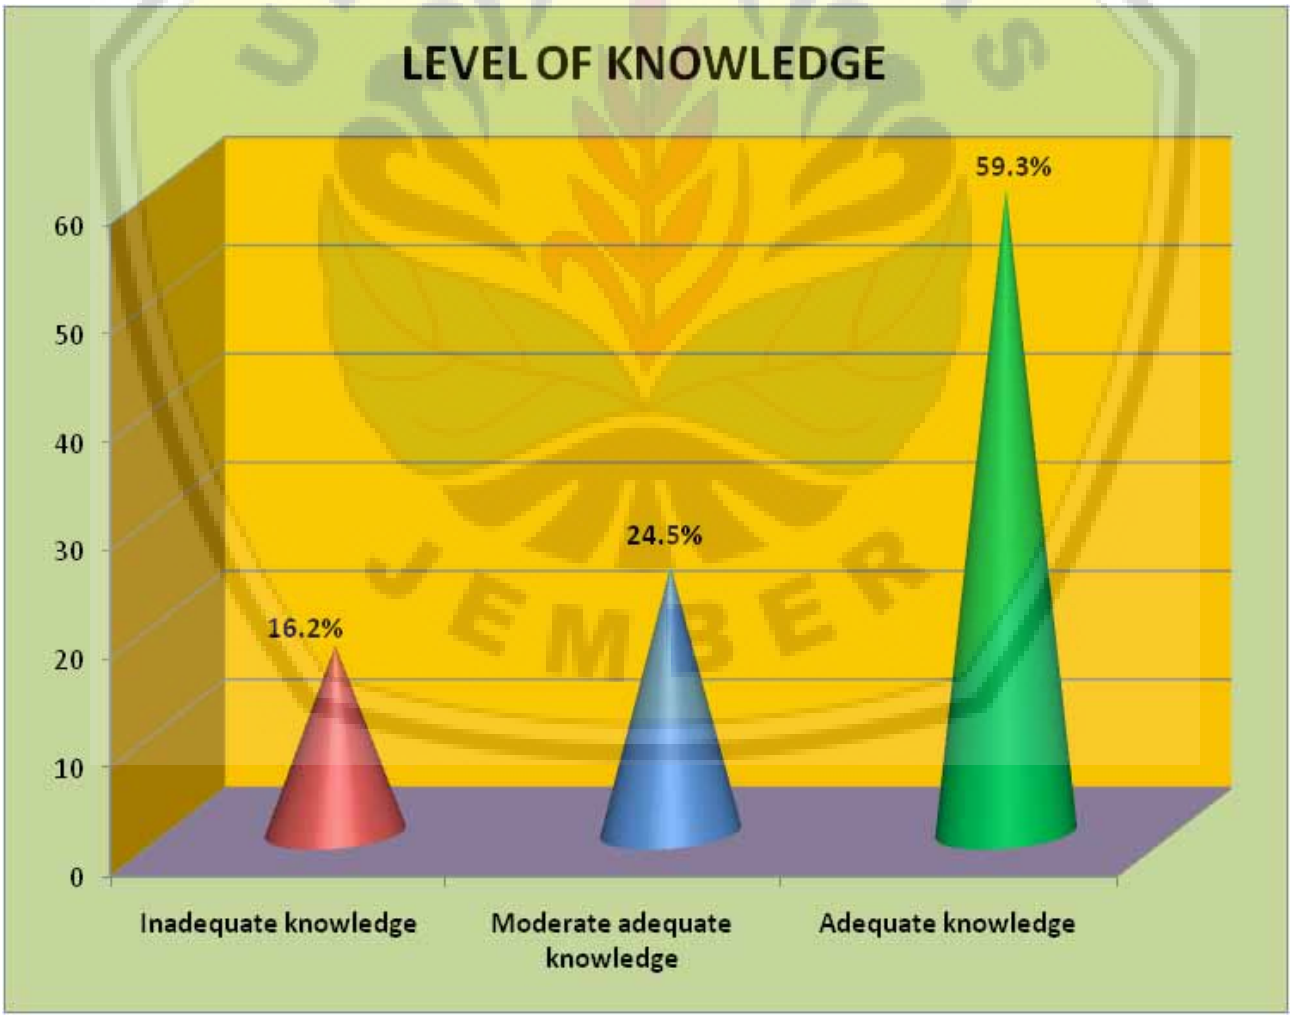

Figure 1: Percentage distribution of knowledge of the mothers of infants: N=500

Conclusion

This study concluded that mothers 59.3% had adequate knowledge, 24.5% had moderate knowledge and 16.2% inadequate knowledge on Complementary feeding among mothers of infants. The mother's of infant's knowledge on Complementary feeding is a peculiar cardinal factor for the reduction of morbidity and mortality especially during the stage of infant. Additional counseling session and health Education was arranged for the mothers of infants who are having Moderate and inadequate knowledge on Complementary feeding.

Type of Manuscript: Decision analysis

Decision Analysis for Vital Pulp Therapy in Mature Permanent Teeth

Krishnamachari Janani[1], Ajitha P.[2], Raghu Sandhya[3]

[1]Post Graduate Student, [2]Professor, [3]Reader, Department of Conservative Dentistry and Endodontics, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Introduction: Vital pulp therapy (VPT) aims to preserve the vitality of the dental pulp and favours long term survival of tooth. It maintains the tooth in its healthy state and eliminates bacteria from the dentin-pulp complex. The vital pulp is capable of initiating several defence mechanisms to protect the body from bacterial invasion, therefore it is necessary to maintain the vitality of an exposed pulp rather than replace it with a root filling material following pulp exposure. Different approaches are available for VPT in extensively decayed or traumatized teeth which includes pulp capping or pulpotomy procedures.

Materials and Method: The PubMed literature search was performed until June 2019 and the results revealed there are no previous reports on highlighting the concept of VPT in permanent teeth. A decision analysis flowchart was made based on the clinical and radiographic findings of dental caries

Results: Various approaches are available depending on the extent of dental caries pulp capping and pulpotomy procedure can be performed

Conclusion: The guidelines in decision analysis for VPT in permanent teeth help in the careful management of the remaining pulp tissue

Keywords: *Direct pulp capping, Indirect pulp capping, Pulpotomy, Reversible pulpitis, Vital pulp therapy.*

Introduction

The diagnosis of pulp condition plays a crucial role in indicating the need forvital pulp therapy[1]. However, diagnosing the pulp vitality is a complex task due to the subjective nature of symptoms and tests carried out for this purpose. Generally, the diagnosis relies on pulp vitality tests, comprising radiographic evaluation, percussion, palpation and thermal tests, but these tests have an estimated subjective accuracy [2]. The main reason for vital pulp therapies failure has been related to pulp complications due to poor diagnoses [3].

Vital pulp therapy (VPT) preserves the function of coronal pulp tissue and the remaining radicular pulp tissue. The treatment outcome promotes good healing capacity of pulp tissues in young patients [4,5]. Favourable outcome is seen more with reversible pulpal injury, marked clinical outcome is seen in non-inflamed pulp exposed to trauma than inflamed pulp exposed to caries [6]. It has been recommended that VPT should be performed only in young permanent tooth because pulp is necessary for the formation of dentine [7]. Since the evidence regarding the effect of the patients age and the status of the root apex on the outcome of vital pulp therapy, did not indicate that this treatment could

Corresponding Author:

Telephone Number: 9444174551

not be performed successfully in old patients and based on the premise of the innate capacity of pulp tissue for repair in the absence of microbial contamination, preservation of the pulpally involved permanent tooth is also considered[8].

Preservation of pulp vitality in VPT aids to withstand fracture against masticatory forces and the survival rate is higher when compared to root canal treated teeth[9,10]. The success of vital pulp therapy is markedly high wherein controlled haemorrhage is achieved. The other factors that affect the success of VPT are adequate blood supply and the presence of a healthy periodontium [11,12]. The prognosis of VPT is significantly reduced in cases with inadequate coronal seal and subsequent bacterial micro leakage[13]. Another important aspect is that pulp capping agents play a major role in success of VPT. Pulp capping material should be biocompatible, non cytotoxic and antibacterial[14]. This review article discusses about the approaches in VPT, namely pulp capping and pulpotomy, in permanent teeth.

Techniques of vital pulp therapy: Vital pulp therapy is indicated following traumatic, mechanical and carious exposure of pulp. High success rate has been reported in teeth with the absence of clinical signs and symptoms. The techniques of vital pulp therapy include

1. Direct pulp capping
2. Indirect pulp capping
3. Partial pulpotomy
4. Full pulpotomy

Based on the clinical findings, signs and symptoms appropriate treatment protocol needs to be followed, as the vitality of pulp is extremely important for viability of the tooth (Table 1).

Table 1: Overview of treatment protocol for vital pulp therapy

Clinical findings	Indication	Treatment
Absence of sign and symptom of irreversible pulpitis	Carious lesion extending into pulpal one fourth of dentin	Indirect pulp capping Step wise excavation of caries
Vital tooth with absence of lingering or persistent prolonged pain	Reversible pulpitis due to trauma and caries	Direct pulp capping
Absence of lingering or persistent prolonged pain	Reversible pulpitis or irreversible pulpitis based on case selection	Full pulpotomy
Absence of lingering or persistent prolonged pain	A "several day trauma" tooth with exposed pulp	Partial pulpotomy

Indirect Pulp Capping: Indirect pulp capping is defined as a procedure in which carious dentin closest to the pulp, is preserved to avoid pulp exposure and is covered with a bio compatible material.

Indication:

1. Teeth diagnosed with normal pulp with no signs and symptoms of pulpitis
2. Absence of spontaneous pain
3. Absence of inter radicular or periapical radiolucency
4. Absence of sharp penetrating pain after withdrawal of stimulus

Contraindication:

1. Large pulp exposure
2. Non-restorable teeth
3. Tooth with poor prognosis

Procedure: Indirect pulp therapy technique prevents pulpal exposure in the teeth with deep carious lesions in which there exists absence of pulpal degeneration or periapical disease[15, 16]. When the infected layer is removed, the affected dentin can then remineralize and the odontoblasts form reparative dentin, thereby preventing pulp exposure. The remaining soft dentine

is covered by pulp capping agent and over a period of two months the degree of remineralisation is tested and remaining residual softened dentine is removed [17,18]. Permanent restoration can be placedif there has been a favourable response and the dentin becomes hard, whereas if caries has reached the pulp, endodontic treatment has to be initiated.

Materials Used: Several materials were used for indirect pulp capping which includes resin modifies glass ionomers, tricalcium phosphate, hydrophilic resin, zinc oxide eugenol. Mineral trioxide aggregate (MTA) and calcium hydroxide are the most commonly used materials in routine practice.

Direct pulp capping: Direct pulp capping is defined as the treatment of a mechanical or traumatic vital pulp exposure by sealing the pulpal wound with a biomaterial placed directly on exposed pulp. This procedure induces the reparative dentin formation and maintains the vitality of pulp.

Indications:

1. Teeth with traumatic exposures or mechanical non-carious exposures less than 24 hours.
2. Iatrogenic exposure during cavity preparation or crown preparation
3. Accidental pin point exposure when excavating deep caries less than 1 sq mm
4. No radiographic evidence of periradicular pathology
5. Normal response with pulp vitality test without tenderness on percussion.

Contraindication:

1. Intra radicular radiolucency
2. Purulent or serous exudate from exposure site
3. External or internal resorption
4. Swelling associated with the tooth
5. Excessive tooth mobility
6. Mature teeth with inflamed pulps, as with carious pulp exposures, should not be pulp capped
7. Pre-operative tooth sensitivity

Procedure: After adequate anaesthesia has been obtained, place a rubber dam and disinfect the tooth with a chlorhexidine solution and gently rinse with aesthetic or sterile saline. If any haemorrhage occurs, dab with a sterile cotton pellet until haemorrhage ceases. Sodium hypochlorite or chlorhexidine solution may be used to aid in haemostasis and the pulp capping material is applied directly to the exposure site. Finally, the tooth is restored with an appropriate filling material

The outcome for direct pulp capping following a carious exposure is unpredictable [19, 20]. When this treatment is performed on infected pulp tissue the success rate is said to decrease drastically [15]. Therefore, direct capping procedures should only be carried out on fresh, traumatic or mechanical exposures, before bacterial plaque has established on the exposure and the underlying pulp has become inflamed [14].

Materials Used: Materials used for direct pulp capping includes Cyanoacrylate, calcitonin, resorbable tricalcium phosphate ceramic, resin-based adhesive composite, bioceramics, Biodentine, ZOE, MTA. Calcium hydroxide has been regarded as the gold standard for several decades.

Recall: The tooth should be evaluated using pulp sensibility test and percussion test at 3–4 weeks, 3 months, 6 months, 12 months and every year thereafter. Hard tissue barriers sometimescan be seen at the treated exposure site as early as 6 weeks after treatment.

Pulpotomy: Pulpotomy has become the treatment of choice for vital teeth exposed to caries [21]. Pulpotomy is described as a procedure that involves the removal of affected or infected pulp at the coronal portion and preserving the remaining vital pulp inorder to maintain its vitality [22].

Full Pulpotomy:

Indications:

1. More extensive inflammation
2. The tooth is restorable and free from advanced periodontal disease.
3. Soft tissues around the tooth are normal with no swelling or sinus tract.
4. Haemostasis should be achieved after complete pulpotomy.

Procedure: Full coronal pulpotomy involves the complete removal of the coronal pulp and the placement of dressing at the canal orifice. The tissue is capped with pulp capping agents in a manner similar to partial pulpotomy. Many chemical compounds have

been used as pulpotomy agents such as formaldehyde, phenol, creosotes and other highly toxic materials which were advocated to mummify the remaining pulp tissue [14]. Although use of formocresol in the full coronal pulpotomy of permanent teeth with pulp exposures has been advocated, it is not recommended in teeth with mature root unless there are behavioural or socioeconomic constraints to performing root canal therapy [23]. It was found that formocresol and glutaraldehyde are associated with systemic toxicity and carcinogenic potential [7].

Materials Used: Calcium enriched mixture, bioceramics, MTA, adhesive resins, resin modified glass ionomers, calcium hydroxide

Recall: The tooth should be evaluated using pulp sensibility test and percussion test at 3–4 weeks, 3 months, 6 months, 12 months and every year thereafter.

Partial pulpotomy: Partial pulpotomy was described by Cvek in the year 1978 [5]. This aims to surgically remove tissue that is irreversibly inflamed and exposed to microorganisms leaving a clean wound surface on healthy tissue [24]. The pulp wound is then irrigated with sterile saline until physiologic haemostasis is achieved and the pulp wound is covered with pulp capping agents. An alternative hemostatic agent sodium hypochlorite (5.25%) can also be used. It has shown to be effective haemorrhage control and surface disinfectant without any detrimental pulpal effects[25, 12]. The wound dressing is then carefully dried and sealed with a suitable material.

Indications:

1. Extent of pulpal inflammation is expected to be greater than normal.
2. Traumatic exposures older than 24 hours and for mechanical exposures in teeth with deep caries.
3. Frank carious exposure
4. Absence of spontaneous pain
5. Radiographically normal appearance of periodontal attachment
6. Absence of tenderness on percussion

Procedure: Anaesthesia was achieved, isolation and surface disinfection were made. At the exposure site, remove 1–2 mm of the superficial pulp tissue using a sterile diamond bur[26]. If excessive bleeding continues, extend the preparation apically. Remove any excess blood by rinsing with sterile saline or anaesthetic solution and dry with a sterile cotton pellet. Sodium hypochlorite or chlorhexidine can be used to facilitate haemostasis. Care should be taken to avoid the formation of a blood clot, which compromises the prognosis [19]. Removal of superficially inflamed pulp tissue and placement of suitable dressing material gives the opportunity to seal the cavity. The reported success rate for partial pulpotomy is 93-96%

Materials Used: The most commonly used materials are calcium hydroxide and MTA. There is no significant difference in outcome results between MTA and calcium hydroxide.

Recall: Follow-up examinations should be performed at time intervals 3 months, 6 months, 12 months and every year thereafter.

Discussions

Reparative dentin formation occurs in small carious lesions, whereas in moderately large cavities, macrophages and lymphocytes are observed under the involved dentinal tubules of the coronal pulp [27, 28]. Acute localized inflammation and liquefaction necrosis were evident in the exposure site. In order to preserve the remaining healthy pulp, it is therefore recommended to remove this infected, necrotic and disintegrated pulpal tissue [29]. A study report which was conducted for a period of two years showed 80% success rate with the placement of calcium hydroxide in teeth with signs of reversible pulpitis. It also showed a high failure rate when vital pulp therapy was performed on the teeth with irreversible pulpitis or pulpal necrosis.

Hosseini et al [30] reported that vital pulp therapy showed 92% success rate even over a period of 10 years. Evidence of continued apical development was found following formocresol pulpotomy procedures on young permanent teeth with incompletely developed apices[31]. Mass and Zilbermanper formed partial pulpotomy in young permanent molars with carious pulp exposure. The result showed that the success rate was 91.4% after a period of 12 months follow up[31].

It was believed that a direct toxic effect from dental materials is predominant cause of pulp damage after direct pulp capping. However, animal studies reported that when restorative materials placed directly on exposed pulp, pulpal necrosis or inflammation do not

occur[32]. Previous report showed that following direct pulp capping with symptoms of irreversible pulpitis success rate of 80% for a period of six months. Unlike most other studies, teeth with lingering pain to thermal stimuli and with sensitivity to percussion were included in the study[33].

Limitations: In deep or extremely deep caries when irreversible inflammation is present, pulp capping is contra indicated. Magnification and illumination are required to perform pulp capping in case of advanced carious lesions.

Conclusion

To improve the success rate of vital pulp therapy, it is necessary to access various vital pulp therapy procedures and to incorporate the latest available information into clinical practice and teaching. Further research and clinical trials are also needed to develop case selection guideline, treatment approaches and materials needed to maximize clinical success. In the near future with more knowledge about the biology of the pulp, vital pulp therapy can be performed with more predictable outcomes.

Does Infertility Affect Socioeconomic Factors? Evidence from India and Bangladesh

L. Ganesh[1], J. Joseph Durai Selvam[2] , K.R. Prasanna[3]

[1]Professor, [2]Associate Professor, Institute of Management, CHRIST, Bengaluru, [3]Research Scholar, Bharath Institute of Higher Education and Research, Chennai

Abstract

This paper attempts to examine the socio economic factors influencing the women infertility in India and Bangladesh. The main aim of this study is to evaluate the impact of socio economic factors on infertile women across India and Bangladesh. Quantitative study was carried out by taking the data from NFHS-4 health survey. Infertile women were selected based on the assumptions. Binary logistic regression was done to find the association between the economic variables and infertility. On contrary to Bangladesh, Wealth index, residence and education were largely influenced by a infertile women in India. The study pays way for further study by gathering information through direct discussion with infertile women.

Keywords: *Reproduction, health, education, societal issue.*

Introduction

Infertility troubles about 8-10% of married persons[1] and have significant impact on individual's health or couple[2]. Because of socio, economic and cultural dimensional issues[1], it is now a subject matter of discussion with health care providers, medical practitioners, medical council and individuals. The decline in fertility rate has not only had the impact on countries population, but also it weakens country's GDP in the long run [3]. Desire to get a child is individual opinion but has greater influence on socioeconomic variables[4]. In this context, current paper attempts to investigate the impact of socioeconomic factors on infertility in two developing countriesviz, India and Bangladesh. Even though India (3287000 sq.km) is 22 times larger in size than Bangladesh (147600 sq.km), Bangladesh performed better than India in Human Development index[5]. This raises questions

Do socio economic indicators outperform Bangladesh with India?

Does fertility rate have any impact on socio economic determinants?

Need and Rationale of the study: Variations of infertility prevalence rate were noticed that infertility occurs due to demographic (age, gender, marital status) and social factors (occupation, income, education) [5]. It was perceived that government or private health centers has not given much importance to reduce the issue rather it has become a baby making industry[6]. Moreover, Indian family planning programs emphasize more on prototype and factors for reproduction but not on the reasons for infertility [7]. Hence there is a need for deeper understanding of infertility and its influence on economic factors. For this, study attempts to understand the changes between India and Bangladesh.

Population in India accounts to 1,360,574,949 billion as on Dec 11, 2018[8] and the fertility rate was 2.41 in comparison to Bangladesh which recorded 167,118,692 million and corresponding fertility rate traced less than 2.0[9]. In spite of good remark in population index, Bangladesh infertility affects 10 - 15 percentof married persons[10]. Human Developmental factors like life expectancy, mortality, fertility rate and literacy shows superior performance than India[11]. Table 1 shows approximately 50 percentage change both in rural and urban Bangladesh (IMR rate) whereas India

shows minimum changes implies Bangladesh are faster than India in saving lives.

Table 1: Health index comparison of India vs Bangladesh

	India		% change	Bangladesh		% change
	2005	2015		2004	2014	
IMR a						
Urban	41.5	28.5	31.3	72	34	52.8
Rural	62.2	45.5	26.8	72	40	44.4
Total	57	40.7	28.6	65	38	41.5
Fertility rate (15-49 age)						
Rural a	2.7	2.3	14.8	3	2.3	23.3
Urban (World bank)	2.9	2.4	17.2	2.7	2.1	22.2
Prevalence of Underweight b						
Urban	32.7	29.1	11.0	42.2	26.7	36.7
Rural	45.6	38.3	16.0	48.8	34.8	28.7
Total	42.5	35.7	16.0	47.5	32.6	31.4

a. NFHS, 2015 a. deaths per 1000live birth, b. Below-2 from median weigh for age of reference population

Moreover,fertility rate of Bangladesh has increased by 0.7 in rural and 0.6 in urban whereas India witnessed 0.4 in rural and 0.5 in urban. Here, percentage change in fertility rate was good in India than Bangladesh. Similarly, India performed well in case prevalence of Underweight. In view of the fact, that India good in health indicators, there exists contrary that Bangladesh outperformed India[5], this creates an urge for a detailed look of comparison between India and Bangladesh with respect to socio- economic factors.

Literature Review: Infertility is the inability of a couple who cannot able to give birth to a child even after one year of regular sexual life[14]. This has greater influence on social, psychological and physical factors [15].

Prevalence of different factors was explored[16] in case of infertility treatment in assisted reproductive clinics at Indore and examined 1000 infertile couples and their Socio-demographic characters responsible for treatment. Occupations like advocates, bankers, academicians were reported as highly influenced towards infertility [17]. However, it is good to note that agriculturists were less affected with infertility.

Another study in Nepal [6] examined the socio-economic and cultural factors affecting the fertility by using Nepal Demographic and Health Survey (NDHS 2006). Bivariate and multivariate analyses were carried out to examine the differences in infertility. Age, education, occupation and exposure towards lifestyle were termed as significant factors for high infertility. A study conducted at Dhaka in Bangladesh on infertile women [18], elaborates the basis of infertility, its treatment and the reason for not having child. They found that infertility exists because of emotional moods, stress and psychological changes of both men and women.

In the nutshell, research papers examine neither the consequences of occurrence nor the cause and effect of infertility. Reviews conclude that, attention has to be given to socio cultural dimension and consequences. [19] Present study explores the socio economic factors responsible for the causes of infertility across India and Bangladesh.

Objectives:

The general objective is to

1. To evaluate the impact of socio-economic determinants on infertile women in India and Bangladesh

The Specific objectives are:

1. To understand the percentage distribution of married women
2. To study the prevalence of infertile women across selected socio- economic variables

3. To examine the impact of socio economic factors on infertility

Methodology

The data was taken from National Family Health Survey (NFHS-4). The selection of infertile women was done in two stages

In India there are 628,826 married women from 29 states and 6 union territories. In the first stage, women in the age group of 20-49, with 5 years of marriage life was selected. Hence,a sample of 381805 women was selected.

In the second stage, to be more focused towards reproduction problem, selection of samples were done with assumptions

a. Married more than 5 years not pregnant

c. No terminated pregnancy

d. Never used contraception

e. Zero total children

A sample of 7092 infertile Indian women was selected. Similarly, out of 18,245 samples, 13150 married women was selected and 183 infertile women was chosen.

The study was carried out in three stages:

a. First, Arithmetic mean was done to find the percentage distribution of socio-economic variables of married women across countries.

b. Next, prevalence rate per thousand populations was carried out to find the attributes influencing infertility over a specified period of time.

c. Finally, binary logistic regression was employed to find the significance between infertility and socio economic factors.

Analysis and Discussion

From Table 2, both the countries have more rural dwellers than urban (India: 72 percent and Bangladesh: 65.7 percent). In case of literacy, 40 percent of the women were illiterate in India as compared to 28 percent in Bangladesh. Bangladesh shows increasing enrollments from primary to secondary education when compared to India. Very few percentage of women attained higher education in both the countries. Study shows that women from Hindu religion were predominant (76%) in India where as Muslims in Bangladesh (90%) which supports the data collection. In case of wealth Index India has more number of infertile women under Below Poverty Line category in compare to Bangladesh where more women are under Above Poverty line.

Table 2: Percentage distribution of married women .

Background Variables	India (%)	Bangladesh (%)

Table 3 provides the prevalence rate of infertile women per thousand populations in both the countries across various economic indicators. Table depicts that In India, 722 rural women in 1000 population suffers from infertility whereas only 278 urban women were infertile. In case of education, most of infertile women were literate (589) with minimum of primary education and majority were Hindus. In case of wealth index, infertile women were more under poor category.

When analyzing the status of infertile women in Bangladesh, infertility was high in urban and were educated. Obviously majority were Muslims. Bangladesh has rich wealth index. Another important socio economic indicator occupation illustrate that half of the women in both the countries were employed.

Table 3: Prevalence rate of infertile women per thousand populations across selected socio economic determinants

Infertility remains in high in rural India because of the lack of accessibility for the treatment and high treatment cost[20]. Study shows that, infertile women in both the countries were educated with minimum of primary education and were working which implies, infertility may occur because of work pressure, postponing of child birth due to low income[16]. Hence infertility was highly significant with occupation which in turn education. But it is interesting that, female employment empowers women in increasing the opportunity costs to become fertile. Hence education has its own positive and negative side in case of infertility.

Impact of socio economic factors on infertility: Logistic regression was carried out in order to quantify the net effect of infertility on the socio economic variables. Since the dependent variable is dichotomous (i.e 1- infertile women and 0- fertile women) in nature, odds ratio gives the measure of association between the influences of explanatory variable on dependent variables.

In India, results shows that Residence (Rural as reference category), Education (Illiterate as reference category) and Wealth index (Poorest as reference category) has the significant influence on infertility. Odds ratio for Residence was 0.875 which implies women in rural area has the negligible chance (0.875) of getting infertile than those of urban women. In contrary, as per prevalence rate (table:3) infertile women were more in rural India. Hence, can conclude that infertility remains high in rural because of lack of effective treatments where rural prefers to go to PHCs because of accessibility, affordability and availability [21], [22]. This shows, urban infertile women has the more chance of getting fertile by availing the treatments in spite of the high expenditure towards infertility.

Odds ratio of education has 1.068 which implies that illiterate women has negligible chance of getting infertile than those of literate. Infertility increases as the education level increases. There may be several reasons for why education changes the reproductive behaviour. In reality, woman with minimum education can be able to read and write, analyze the situation around her and improves her reproduction[23]. Also surroundings and situational learning by media, even illiterate woman dwelling in cultured area has the chance of diverse attitude towards infertility. For high educated women, there may be delay in getting nuptials which in turn affects fertility rate. On the whole, education has the powerful effect in reducing the fertility rate and also suppresses or delays in fertility [24]. Similarly, in case of wealth index, poor women have the less chance of getting infertile than rich as they are early married, less prone to stress situation and urban lifestyle.

Contradict to the above Indian situation, none of the explanatory variables influences infertility in Bangladesh. It is obvious that the government and NGO policy makers' and donors' main concern is to emphasize family planning and maternal & child health care in Bangladesh [25]. However, there are also contradicting urging in favor of providing infertility services in a developing country like Bangladesh.

Table 4: Impact of socio economic variables on Infertility

Variables	India				Bangladesh			
	B	S.E	Sig	Exp (B) odds-ratio	B	S.E	Sig	Exp (B) odds-ratio
Residence (ref. rural)	-0.133	0.031	0.000	0.875	-0.247	0.171	0.149	0.781

*P<.01

Conclusion

The frequency of infertility is escalating day by day. Women are forced to accept the burden of infertility even when the problem cannot be traced to any reproductive malfunctioning on her part. Infertility grounds woman's powerlessness to achieve the desired social role, it is often associated to psychological distress [26].

Customarily, Infertility intimidates a woman's distinctiveness, position and monetary protection and act as a source of anxiety leading to lower confidence. This study concludes that, infertile women are a source of socio-economical knowledge with distressing consequences on social health of infertile couples. India facing economically influenced infertile women especially with the residing type, education and wealth index than Bangladesh. Infertility remains a neglected issue in Bangladesh's reproductive health policy; instead, the emphasis has always been on the problem of overpopulation[27]. Study provides scope in clarifying the childlessness among literate women and higher income group.

The Effectiveness of Warm Saline Gargles on Sore Throat among Patients after Endotracheal Tube Extubation in Selected Hospital

Lincy V.O. Babu[1], Deepak Sethi[2], Dipali Dumbre[3]

[1]M.Sc. Nursing, Department of Medical Surgical Nursing (Critical Care Nursing), [2]Assistant Professor, Department of Medical Surgical Nursing, [3]Tutor, Department of Medical Surgical Nursing, Symbiosis College of Nursing, Symbiosis International (Deemed University), Pune

Abstract

Background & Objective: Sore throat is a common morbidity following tracheal intubation in the post-operative period. Our aim was to assess the effectiveness of warm saline gargles on sore throat after endotracheal tube.

Method: A Quasi Experimental: Non randomized control design group was conducted involving 40 endotracheal tube extubated patients who completely out of anaesthetic effect, endotracheal induced sore throat, undergone general anaesthesia in hospital and 2nd post-operative day. After obtaining informed consent. Patients were randomly allocated into two groups of 20 patients each. Warm saline gargles (Isotonic solution 200ml at temperature 30-40 degree Celsius) on sore throat among patients after endotracheal tube extubation in experimental group for 2 times a day for 2 days. Tool used in the study are Numerical pain scale, GRABS- Hoarseness of voice, Modified Bedside Swallowing Scale.

Results: The average change in pain score and GRABS- Hoarseness of voice in experimental group was significantly higher compared to control group. Average pain score in pre-test was 7 which was 1.2 in post-test, t-value 15.2 with df 19 (less than 0.05), null hypothesis rejected. Average GRABS score in pre-test was 10.3 which was 2.7 in post-test, t-value 11 with df 19(less than 0.05), null hypothesis is rejected. p-value were large (greater than 0.05), none of the demographic variables was found to have significant association with the endotracheal induced throat pain, hoarseness of voice.

Conclusion: The effectiveness of warm saline gargles in endotracheal tube extubated patients, null hypothesis is rejected. The association in effectiveness of warm saline gargles over on extubation inducing sore throat with selected socio-demographic variables, null hypothesis is accepted.

Keywords: *Endotracheal tube extubation, sore throat, warm saline gargles.*

Introduction

Endotracheal extubation is a medical procedure in which a tube is placed into the wind pipe (trachea) through the mouth or nose is been removed after the indicated procedure. The common problems after endotracheal tube extubation are common after laryngoscopy and insertion of an orotracheal tube. These are typically of short duration, such as sore throat, lacerations of lips or gums or other structures within the upper airway, chipped, fractures or dislodged teeth and nasal injury. Other complications which are common but more serious include accelerated or irregular heartbeat, high blood pressure, elevated intracranial and intraocular pressure and bronchospasm.

A complaint of postoperative pharyngeal discomfort is so prevalent that it is almost expected by patients and anesthetist alike as an unavoidable part of routine anesthesia. Complaints range from minor throat irritation to debilitating pain, inability to swallow and temporary voice change and are a frequent observation

on the postoperative visit. There is no data regarding the magnitude of post-operative airway complications and their associated risk factors in Ethiopia. The finding of this study confirmed pervious observations that the large the ETT size, the higher the incidence of postoperative respiratory morbidities. Although tracheal intubation remains as absolute necessity for good airway protection for different surgical procedures, recommended to use the smaller ETT sizes (6.5.,7.0 mm ID) to minimize the pressure induces trauma on the laryngeal and tracheal mucosae. [1]

Endotracheal intubation during general anaesthesia often leads to postoperative complication like sore throat, cough and hoarseness of voice. In this study, we tried to determine the effects of controlled ETT cuff pressure in these complications. In the present study the 2 groups were comparable with respect to age, gender, weight, height, BMI and during surgery. The incidence of POST at 12 or 24hr. in the group with controlled ETT cuff pressure was significant difference in the incidence of POST at 1hr between the 2 groups. Proper control of ETT cuff pressure during general anesthesia with the help of a manometer significantly reduces the incidence and severity of POST.

Material and Method

A Quasi Experimental study design with quantitative approach was used, as this study was aimed, the approach was found to be most appropriate. Aexperimental group was given warm saline gargles (isotonic solution 200ml at temperature 30-40 degree Celsius twice for 2 days) and control group was given no intervention. This study was conducted in selected hospital of Pune city. The selection was based on easy accessibility, cooperation and availability of samples. Total 40 Endotracheal tube extubation induced sore throat patients of selected hospital, Pune city who met the inclusion criteria were selected. Tool used for the collection of data was a Modified observational checklist (Numerical Pain Scale, Modified Massey Swallowing Scale and GRABS- Hoarseness of voice). Findings: The analysis and interpretation of the data collected to determine the Effectiveness of warm saline gargles on sore throat among endotracheal tube extubationis carried out based on objectives set by the researcher taking the level of significance as 0.05

Table 1: Effectiveness of warm saline gargles on sore throat after endotracheal extubation based on numerical pain scale n=20, 20

Pain	Experimental				Control			
	Pre-test		Post-test		Pre-test		Post-test	
	n_1	%	n_1	%	n_2	%	n_2	%
No Pain (Score 0)	0	0%	5	25%	0	0%	0	0%

Post-test	2.7	1.7			

Discussion

A similar study was conducted study on A Quasi experimental study to determine the effect of warm saline gargles on sore throat among patients after endotracheal tube (ET) extubation in Hinduja Hospital. Fifty patients who developed sore throat after endotracheal tube extubation were randomly assigned to control and experimental group. An experimental approach was used and patients intubated for 3 to 48hrs and had regained gag reflex were included for the study and those with altered sensorium and pre-existing sore throat were excluded. Warm saline gargle thrice a day/ standard care was given to the patients in both groups for two days and post-test assessment done thereafter. The calculated 't' value for the post test in control and experimental group is 5.52 which is more than the table value at 0.05 level of significance, hence null hypothesis is rejected. There was significant relation between sore throat and hoarseness of voice and variables like size of tube, use of lubricant jelly and number of attempts.

Conclusion

The following interpretation can be done from the findings of the study. The analysis of the data reveals that the effectiveness of the warm saline gargles is highly significant for reduction of sore throat pain among endotracheal tube extubation patients as measured through numerical pain scale, modified swallowing bedside scale and GRABS- Hoarseness of voice.

A Study to Assess the Effectiveness of Beetroot Juice in Reducing Blood Pressure among Post Menopause Women Having Elevated Blood Pressure in Selected Central Region of Gujarat

Liza Mahida[1], Siddaram Sarate[2]

[1]Student, Manikaka Topawala Institute of Nursing, [2]Assistant Professor, Charotar University of Science and Technology, Changa

Abstract

Background of the Study: In the contemporary epoch, In India there is accelerated evolution in health due to expanding strain of prevailing chronic non communicable diseases, supremely cancer, hypertension, chronic lung disease diabetes mellitus and stroke as well as increased age was one the cardinal cause of elevated blood pressure.

Objectives: 1) To determine the effectiveness of beetroot juice in reducing blood pressure among post menopause women having elevated blood pressure. 2) To find out the association between the selected demographic variables and blood pressure among post Menopause women.

Methodology: A quasi experimental study was carried out by electing 64 post menopause women through non probability convenience sampling technique. Demographic data was collected by questionnaire as well as blood pressure was monitored by using digital sphygmomanometer.

Result: Majority of menopause women belongs to the age group between 64-76 years. Menopause women having abnormal BMI above 25 (P= 0.013 at 0.05 level of significance) have increased risk of elevated Blood pressure. Blood pressure was detected higher among women who have attained menopause at later age (>45 years). The significant difference was discovered in pre- test and post- test blood pressure level among participants included in experimental group however; there was no significant difference among participants included in control group at 0.05 level of significance.

Conclusion: Elevated blood pressure can be reduced by regular consumption of beetroot juice among post menopause women.

Keywords: *Elevated blood pressure, Post menopause women, Systolic blood pressure, Beetroot juice, Diastolic blood pressure.*

Introduction

Health is “a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity” (WHO)[1]. It is a treasured facet of every mankind, as well as it is a heavenly gift for a person. Health is sustained not simply as a result of up gradation and utilization of health science technologies, but it also can be achieved through the ingenious life style of personal and community such as exercise, yoga, diet pattern and meditation[2].

There are different etiological factors that cause fluctuations in blood pressure levels among Menopause women such as Age, Hormonal changes, Family history of high blood pressure, Lifestyle, having high blood pressure during pregnancy are the prospect to develop hypertension at the age of menopause, Being

obese, consumption of alcohol, Stress, Lack of physical exercise, Chronic kidney disease, Smoking, Adrenal and thyroid diseases, Being obese, High Cholesterol and triglyceride levels[3][4].

As the Age increase among both male and female is most commonly blood pressure (BP) is increased. However, the prevalence of elevated blood pressure in man is lesser then in postmenopausal women, 41% of postmenopausal women having hypertension. Majority of 25% of the female world population is suffering from hypertension[5]. The risk factors of elevations in blood pressure in women are associated with cardiovascular risk among women having age more than 60 years. As per the data of the United States, there is prevalence of hypertension among women aged 60 years or greater is more than 75% [6]. The data set of National Health and Nutrition Examination Survey (NHANES) IV (1999–2004) illuminate that, the percentage of men and women having elevated Blood pressure was 50.8±2.1% and 55.9±1.5% respectively[7].

As per the data of India Today (2017) in a world there are 1.13 billion adults are suffering from hypertension. In India there are 23.5% Men and 22.60% women suffering from hypertension [8].

The decrease of the hormone oestrogen in postmenopausal women causes elevation in endocrine metabolic dysfunctions, like variation in lipid profile and blood pressure. So that there are various alternatives used and one of those alternatives is physical exercise and diet rich in nitric oxide (NO) that is a dynamic vasodilator for prevention and treatment [9].

Beetroot is the round, dark red, small root of a plant, can be eaten or cooked as a vegetable, especially used in salad. The main content of it is fibre (2-3%), carbohydrates (8%) and water (87%). It contains 6.4 to 12.8 mg/kg nitrate which helps in reducing elevated blood pressure [10].

Methodology

The study was executed by using quantitative research approach with quasi experimental study design. The elected population for the study was post menopause women having elevated blood pressure above 130/80 mm of hg in selected central region of Gujarat. Participants were selected by calculating power analysis with using the formula

$$n = 2(\sigma/\Delta)^2 (Z_\alpha + Z_{1-\beta})^2.$$

n = Sample size, σ = Standard deviation = 1(taken from pilot study), Δ = critical difference = 0.5 (constant value), Z_α = Error (5%) = 1.96, $Z_{1-\beta}$= Power (80%) = 0.84.

There were 64 post menopause women selected and assigned in to two groups by using non-probability convenience sampling technique, the participants who elected in experimental group were given 400 ml of beetroot juice daily for 10 days and no intervention given to the control group participants. Independent variable was beetroot juice as well as dependent variable was elevated blood pressure level and demographic variables were age, age of menopause, BMI, lifestyle, treatment, family type, Smoking, tobacco chewing, alcohol consumption, family history, exercise, food habit and health check-up. All the data was collected by utilizing demographic questionnaire and blood pressure was monitored by using digital sphygmomanometer Med tech Nova checker B. P. Monitor 12T. Pilot study was conducted in changa village to identify feasibility of the samples and reliability of the tool. The main study was conducted in different old age homes. Moreover, the data was analysed and interpreted by using descriptive and inferential statistics. Nutritive value of beetroot juice was given by nutrition.

Results

The analysed finding of the study were exhibited that among 64 post menopause women having elevated blood pressure, majority of them 34 (53.4%) menopause women belongs to the age group of 64 -76 years as well as the mean ± SD was 70.6 ± 6.66 in control group and in experimental group mean ± SD was 70.31 ± 7.13. Especially 26(81.3%) participants were in hypertension stage II and 6(18.8%) were in hypertensive crisis in control group as well 46(71.9%) participants were in hypertension stage II and 9 (28.1%) were in hypertensive crisis in experimental group. Moreover, 46(71.9%) have attained menopause at the age of 40-48 years as well as 28 (43.75%) participants were having BMI 25-29.9. All the 64 (100%) participants were having moderately active lifestyle, no smoking, no tobacco chewing, no alcohol consumption and all were vegetarian. Most of the participants [62(96.8%)] were live in nuclear family, [39 (60.9%)] not taking any treatment, [41 (64.06%)] having family history of hypertension, [43(67.18%)] not doing exercise regularly and [44(68.7%)] not go for regular health check-up.

The paired t test was calculated to assess the significant change in blood pressure level in pre-test post-test S BP and pre-test post-test DBP score among both the groups, The value for control group S BP was obtained t value = 0.976, Table value = 2.04 (P = 0.336) and for DBP was obtained t value = 0.070, Table value = 2.04 (P = 0.945) as well as for experimental group S BP was obtained t value = 12.741, Table value = 2.04 (P = 0.000) and for DBP was obtained t value = 5.629, Table value = 2.04(P = 0.00004) illustrates that no significant change was found in blood pressure level in pre-test, post-test S BP and pre-test, post-test DBP score among control group but, there was significant change and in blood pressure level in pre-test, post-test S BP and pre-test, post-test DBP score among experimental group.

Unpaired t test was carried out to assess significant change in Blood pressure level in both the groups. The calculated value was obtained t value = 9.445, Table value = 2.0 (P = 0.000). It suggests that there was significant change in Blood pressure level in both groups.

The calculated Chi square ($\chi 2$) value = 9.495, Table value = 5.9 (P=0.013) exhibit there was significant association between elevated blood pressure of post menopause women and BMI in control group as well as experimental group and there was no significant association with other demographic variables at P <0.05 level of significance so, research hypothesis was accepted for BMI Hence, it was rejected for other demographic variables.

The Odds ratio suggest the risk of occurrence of hypertension among post menopause women by various risk factors like, Age of menopause (2.094), BMI (0.183), Family history (1.255), Exercise (1.461) and Health checkup (1.667) .

Conclusion

The study concluded that beetroot juice has tremendous effect in reduction of elevated blood pressure as well as abnormal BMI, Increase age of menopause, Family history, Lack of exercise and lack of regular health checkup are the influencing factor in occurrence of hypertension. Along with it highlights that beetroot plays vital role in lowering elevated blood pressure among post menopause women having elevated blood pressure above 130/80 mm of hg. Within 10 days of time period.

A Study on Customer Preference towards Online Shopping of Organic Food Products in Coimbatore District

M. Mohanraj[1], J. Suresh Kumar[1], A.T. Jaganathan[2]

[1]Ph.D. Research Scholar [Management], Department of Business Administration [PG], K.S. Rangasamy College of Arts and Science (Autonomous), Tiruchengode, Tamil Nadu, India, [2]Associate Professor in B.B.A., Vivekanandha Arts and Science College for Women, Veerachipalayam, Sankari, Tamil Nadu, India

Abstract

In today's scenario, online shopping is playing an important role in the life of human because time is precious for every people. People have become very busy in their work and they are unable to make their shopping daily. In this article we are going to discuss regarding the preference of organic food products through online shopping (Basha, 2014)[1]. Awareness of organic products has been increasing steadily and Consumers are started to prefer organic food products because they are healthy, safety and environmental friendly (Brijesh Sivathanu, 2015)[2]. Consumer of organic food products are willing to purchase organic products through online shopping due to the time and travel constraints (Ramesh, 2015)[10]. In this paper the researcher has collected the sample size of 80 and tools used for the analysis are percentage analysis, chi- square analysis and Anova. The result of the study is found that the consumers are purchasing the organic food products through online shopping, especially for the health purpose.

Keywords: *Customer preference, organic food products, health and online shopping.*

Introduction

Nowadays health of the human is concentrated well by everyone due to the changes in the food habits. In the current scenario people are moving fast towards their work and they are not concentrated on the health by having the conventional food (Chandrashekar, 2014)[3]. These kind food habits are affecting the health of human and causing many diseases. Awareness of organic food products has increased in the environment and consumer are started to consume it mainly for the healthy, safety and the environmental issues in society (Dash, 2014)[4]. At present consumer of they are using online shopping for the purchase of the products from the various countries and they are getting it with the safe and comfortably. With the help of online shopping time, travel and money has been saved. Consumer are started to purchase all kind of products through online shopping. Consumers of organic food products are started using online purchase of products that are available in various places.

Customers are preferring products based on their attitudes towards the various alternative products available (Kumar, 2015)[5]. Consumer prefer organic food products with the opinion provide by the others through word of mouth and at the same time the consumer will get reviews from various people and are influenced (Paluri, 2014)[7].

Online shopping has become the trending to purchase the products. Based on the online shopping the brief description of the products can be found and also comparison of organic products is made easily (Sharma, 2016)[11]. Customers have purchased organic products which are healthy when compared to conventional products (Rajeswar and Magesh, 2016)[9]. An organic food product helps them to have the better life.

Corresponding Author:
Mr. M. Mohanraj

Statement of the Problem: Awareness of organic food products has increased by the consumer and there is a demand of the organic food products in many areas and at the same time, time constrains is there for the consumer (Narmilan, 2015)[6]. Online shopping helps the consumers to purchase the products from various places easily. Consumers prefer online shopping for the purchase of organic products and the time has been utilized effectively (Priya, 2016)[8].

Objective of the Study:

- To study the customer preference towards online shopping of organic food products
- To find the factors influencing consumers to prefer online shopping for organic products
- To find the constrains faced by the consumer towards the demand of products
- To provide valuable suggestion for the improvement of service in future

Research Methodology

Research Methodology is the methodical way to solve the problem. There is diverse kind of methodologies used in different types of investigation and the term is usually considered to include research design, data collection and data analysis.

Research Design: Research design is the map, arrangement and approach of analysis concerned so as to counter to research questions and to control conflict. Research design depends on depth and extent data necessary of the costs and benefits of the research. Descriptive research is adopted for this research.

Sources of data

Primary data: The primary data was collected through questionnaire from the customers in Coimbatore who are using the online shopping to purchase organic products.

Secondary data: The secondary has been collected from Journal, Records, Books and Company profile.

Research instrument: Data was collected through questionnaire.

Sample size: The sample size for the study was 80.

Tools for analysis: The data collected through the questionnaire has been analyzed by using the tools given below.

- Percentage Analysis.
- Chi-Square test.
- Anova

Percentage Analysis: The percentage analysis method is used to calculate the percent of the favorable and unfavorable responses.

Percentage = [Number of respondents/
Total number of respondents]×100

Chi Square: Chi-square is a statistical test commonly used to compare observed data with data we would expect to obtain according to a specific hypothesis.

The formula to calculate chi-square test:

$$X^2 = \sum \frac{(obs - \exp)^2}{\exp}$$

Obs - Observed frequency, Exp - Expected frequency.

Materials and Method

1. Percentage Analysis

Table 1

Characteristics	Frequency	Percent	Valid Percent
Buying decision through online shopping of the respondent			
Strong impact	35	43.8	43.8
Slight impact	19	23.8	23.8
Bad impact	26	32.5	32.5
Total	**80**	**100.0**	**100.0**

Characteristics	Frequency	Percent	Valid Percent
Payment through online of the respondent			
Highly satisfied	19	23.8	23.8
Satisfied	23	28.8	28.8
Neutral	15	18.8	18.8
Dissatisfied	14	17.5	17.5
Highly dissatisfied	9	11.3	11.3
Total	**80**	**100.0**	**100.0**
Purchasing organic food of the respondent			
Highly satisfied	17	21.3	21.3
Satisfied	19	23.8	23.8
Neutral	14	17.5	17.5
Dissatisfied	14	17.5	17.5
Highly dissatisfied	16	20.0	20.0
Total	**80**	**100.0**	**100.0**
Online Service of the respondent			
Highly satisfied	16	20.0	20.0
Satisfied	23	28.8	28.8
Neutral	9	11.3	11.3
Dissatisfied	17	21.3	21.3
Highly dissatisfied	15	18.8	18.8
Total	**80**	**100.0**	**100.0**
Organic food benefits of the respondent			
Highly satisfied	28	35.0	35.0
Satisfied	13	16.3	16.3
Neutral	17	21.3	21.3
Dissatisfied	6	7.5	7.5
Highly dissatisfied	16	20.0	20.0
Total	**80**	**100.0**	**100.0**
Advertisement of organic products of the respondent			
Idea of delivering the message	26	32.5	32.5
Frequently changes in add	23	28.8	28.8
Logical reason	12	15.0	15.0
Branded modelers	19	23.8	23.8
Total	**80**	**100.0**	**100.0**

2. Chi-Square

Association between Age and Purchase through online shopping: An attempt was made to study the association between Age and Purchase through online shopping. For this purpose the respondents classified on the basis of chi-square test between Age and Purchase through online shopping. The data are tabulated and presented in the table 2.

Null hypothesis (Ho): There is no association between Age and Purchase through online shopping of the respondent.

Alternative hypothesis (H1): There is an association between Age and Purchase through online shopping of the respondent.

Table 2: Age of the respondent and Purchase through online

Age		Purchase through online shopping					Total
		Highly satisfied	Satisfied	Neutral	Dissatisfied	Highly dissatisfied	
Age of the respondent	Below-25	9	7	0	0	8	24
	25-30	9	0	10	0	8	27
	30-35	10	6	7	6	0	29
Total		**28**	**13**	**17**	**6**	**16**	**80**

Table 2.1.1: Age of the respondent and Network facility of the respondent

Chi-Square Tests			
	Value	Df	Asymp. Sig. (2-sided)
Pearson Chi-Square	35.387 [a]	8	.000
Likelihood Ratio	50.687	8	.000
Linear-by-Linear Association	.673	1	.412
N of Valid Cases	80		

a. 7 cells (46.7%) have expected count less than 5. The minimum expected count is 1.80.

Inference: It is incidental; there is an association between Age and Purchase through online

3. **Anova:** Association between gender and buying decision of the respondents

Null Hypothesis (H0): There is no significant difference between gender and buying decision of the respondents.

Alternative Hypothesis (H1): There is no significant difference between gender and buying decision of the respondents.

Table 3: Gender and buying decision of the respondents

Gender of the respondent	Sum of Squares	Df	Mean Square	F	Sig.
Between Groups	12.152	4	3.038	31.492	.000
Within Groups	7.235	75	.096		
Total	**19.388**	**79**			

Inference: It is determined that the calculated value is (0.00) which less than the table value (0.05). Therefore the null hypothesis was rejected and concluded there is significant difference between gender and buying decision of the respondents.

Findings: The study has found that there is a strong impact with 43.8% in buying decision through online shopping of organic food products, 28.8% are satisfied with the Payment through online for their safety, 23.8% used to purchase organic products in online shopping, 28.8% of the respondents felt satisfied with the online service to purchase products, 35% of respondents felt that the organic food products benefit for their health and logical reason of the advertisement has to be improved to create effective customer support on purchase. Chi-square test has resulted that there is an association between Age and Purchase through online and Anova test has found that there is significant difference between gender and buying decision of the respondents.

Conclusion

Organic products are emerging to meet the demand in the market in order to satisfy the needs of the customer (Wee, 2014)[12]. Awareness of organic food products has to be used well to increase the consumption and online shopping helps the customers to purchase the organic

products easily without moving from various places. Customers felt that still online service to be improved for them to make more purchase in the safer manner. Buying decision of the customers has to be concentrating well for making them to be satisfied.

Severe Early Childhood Caries, Hypoplasia-Associated Severe Early Childhood Caries and Deciduous Molar Hypomineralization amongst 3 to 6 Years Old Anganwadi Children in Pune, Maharashtra: A Cross-Sectional Study

Mahima Bulani[1], Sahana H. Shetiya[2], Dipti Agarwal[3], Anmol Mathur[4]

[1]MDS, Public Health Dentist, [2]MDS, Professor and Head, Department of Public Dentistry, Dr. D.Y. Patil Vidyapeeth, Pimpri ,Pune-18 Maharashtra, India, [3]MDS,Public Health Dentist, [4]MDS, Associate Professor, Department of Public Health Dentistry

Abstract

Purpose: Systemic insults leading to hypoplastic enamel defects predisposing to early childhood caries have been termed as Hypoplasia-associated early childhood caries (HAS-ECC) and have been proposed to have a distinct dual etiology. Thus, the study was undertaken to find its prevalence and dual etiology.

Material and Method: A cross-sectional survey was conducted amongst 775 anganwadi children aged 3 to 6 years to assess severe early childhood caries, hypoplasia-associated early childhood caries and deciduous molar hypo-mineralization using National Institute of Dental and Craniofacial Researchcriteria (NIDCR) and European Academy of Paediatric Dentistrycriteria (EAPD) respectively. Prenatal, perinatal and postnatal history was obtained by maternal interviews using a pre tested questionnaire. Descriptive statistics is presented as frequency, percentage and means using SPSS version 16.

Results: The prevalence was found to be 29.93%,5.54% and 4.12%respectively for severe ECC, hypoplasia associated ECC and deciduousmolar hypo-mineralization. Caries experience increased with age. Maternal interviews revealed that 79.10% mothers were underweight,60.50% had young maternal age and 62.80% mothers used smokeless tobacco during pregnancy. Currentnutritional status was found to be normal for 67.40% children while the sweet score was found to be in the “watch out zone” for all the children

Conclusion: Thus, the presence of these prenatal, perinatal and postnatal factors amongst these children indicate the systemic influence leading to Enamel Hypoplasia (EHP) along with cariogenic dietary practices thereby signifying the probable dual etiology to be present amongst the children diagnosed with HAS-ECC.

Keywords: *Dentalcaries, Dental Enamel Hypoplasia, Hypomineralization.*

Introduction

Early childhood caries (ECC) is a public health problem affecting the infants and preschool children worldwide which if untreated may result in higher risks of new carious lesions in primary and permanent dentition, increased treatment costs, hospitalizations, loss of school days, increased days with restricted activity thereby having a negative impact over the quality of life of the children[1,2]

Caufield et al[3] stated that along with improper feeding practices, prolonged sugar beverage consumption, improper maintenance of oral hygiene and the hypo plastic enamel defects can also cause ECC and

Corresponding Author:
Dr. Sahana H. Shetiya
MDS. Professor and Head, Department of Public Health Dentistry, Dr. D.Y. Patil Vidyapeeth, Pimpri Pune, 18 Maharashtra. India

termed it as HAS-ECC . There are basically two major developmental enamel defectsie., enamel hypoplasia and enamel opacity/hypomineralization being reported by Salanitri and Seow[4]. EHPis a quantitative disturbance of mineralized tissue formation during tooth development occurring due to insult to the embryonic cells during embryonic development.[3]. Enamel hypomineralization is a qualitative defect of the enamel with alteration in the translucency of enamel and no loss of tooth structure. Hypomineralization in second primary molar has been termed as Deciduous Molar Hypomineralization (DMH)[5].

Thus, this study was undertaken to find the prevalence of Severe ECC, HAS-ECC and DMH to have better understanding towards the proposed distinct etiology of HAS-ECC amongst the anganwadi children in Pune, Maharashtra through a questionnaire study.

Material and Method

A cross-sectional survey was conducted from July–September 2015 amongst nineteen anganwadi's selected from West zone of Pune city, Maharashtra according to convenience sampling technique. The sample size of 775 children aged 3-6yrs was calculated at 95% confidence level using the formula for descriptive studies based on published data[6] where in the prevalence of enamel hypoplasia with caries was 34.11%.Ethical Clearance was obtained. Photographic and clinical calibration was conducted for the examiner. Intra-examiner reliability was calculated using Kappa and weighted Kappa for diagnosis of dmfs for S-ECC, HAS-ECC staging and DMH which ranged from 0.7 to 0.92. The interviewer was trained formaternal interviewing using a pre tested questionnaire. Informed consent was obtained from the parents of the children.

The demographic details of the participants were collected from the anganwadi staff records. Socioeconomic status was recorded using Kuppuswamy scale[7]. Clinical examination was conducted on wet teeth by a single well trained examiner in daylight conditions using a portable penlight torchor under natural light to diagnose S-ECC, HAS-ECC and DMH.

Caries was diagnosed according to World Health Organization (W. H. O)[8] criteria for caries diagnosis using dental caries index i.e dmfs index. S-ECC was diagnosed on the basis of criteria laid down by NIDCR proposed by Drury etal[9]. HAS-ECC was diagnosed and classified as per the staging proposed by Caufieldetal[3]. DMH was diagnosed on the basis of EAPD criteria proposed by Weerheijmet al[10].

The information on various prenatal (maternal) factors and nutritional status (BMI) along with perinatal and postnatal factors that influence the development of enamel hypoplasia were obtained by face-to-face maternal interviews of children diagnosed with HAS-ECC using a specially designed, validated questionnaire. The content validation of the questionnaire was carried out by 15 subject matter experts whereby content validity ratio was calculated. The final questionnaire comprised of 14 questions on prenatal, perinatal and postnatal factors. It was then translated to local language (Marathi) and back-translated and subjected to reliability analysis, pretesting and pilot testing. The nutritional status of the child was assessed using WHO child growth standards[11] along with sweet score of the children diagnosed with HAS-ECC were recorded as excellent, good and in the watch out zone [12]. Duplicate examination was done during the course of the survey .

Statistical Analysis: Data collected through the assessment form was entered into Microsoft Excel spreadsheet 2010. Descriptive statistics was performed using Statistical Package for Social Sciences (SPSS) version 16.

Results

Oral Examination: Table 1 Presents the prevalence of S-ECC, HAS-ECC and DMH according to gender. Amongst the children 271 belonged to lower SES,459 upper lower and 45 belonged to lower middle class.

Table 2 Most of the children belonged to stage 1 of HAS-ECC wherein the primary teeth had EHP and a minor to moderate degree of caries. The staging/severity of HAS-ECC increased with an increase in age of the children which was found to be statistically significant ($p<0.05$, Spearman's Correlation value=0.718). Demarcated opacity was the only defect found for DMH.

Table 3 Caries experience of children diagnosed with S-ECC and HAS-ECC shows increased prevalence as age advances.

Table 4 Prenatal factors indicated that mothers were underweight with 44% consuming milk and milk products (once a week) and 51% green leafy vegetables (2-3 times a week). Dietary insufficiency was seen and 93.02%consumed nutritional medication during

pregnancy. Postnatal factors indicated that recurrent diarrhea was seen in 14% and chronic respiratory infection probably in 19% during infancy and 84% of them breast fed their infants.

Table 1: Genderwise distribution of S-ECC, h AS-ECC, DMH

Gender	Children Examined	S-ECC	HAS-ECC	DMH	Without Disease
	N (%)	N (%)	N (%)	N (%)	N (%)

Discussion

The study was conducted at anganwadi which are preschools developed under the Integrated Child Development Scheme (ICDS) for the children of low socioeconomic status where they are provided with preschool education, mid-day meals, regular health and nutritional assessment and monitoring. [13].

S-ECC - The prevalence of S-ECC found in this study is comparable to the prevalence of results reported by another study conducted among 30% Bangalorechildren[14]. The prevalence of HAS-ECC was found to be 5.54% in the present study (Table -1,2). However, amuch higher prevalence for enamel defects and dental caries has been recorded amongst Brazilianchildren (24.56% and 48.4%)[15], Connecticut Headstartchildren (50%)[16] and Chinese children (22.17%)[17] all reported with higher enamel hypoplasia. This difference could be due to the difference in the criteria used for recording enamel defects. Also HAS-ECC was found to be a subset of S-ECC contributing 18.5% to the S-ECC group confirming the propositions put forth by Caufield et al[3]. The severity of HAS-ECC was found to increase with the age of the children. EHP as antecedent along-with the cariogenic dietary consumption has been attributed as the cause.

DMH – The prevalence of DMH of 4.12% (Table-1) is comparable to the prevalence recorded amongst Iraqichildren (6.6%)[18]and Nigerianchildren (4.6%)[19]. DMH has been classified into demarcated opacity, post eruptive enamel breakdown, atypicalrestorations, extractions due to hypo-mineralization and un-eruptedteeth. Demarcated opacities (100%)were the only type of defect recorded in this study. Similar findings were recorded amongst Iraqi children showing 92.8% demarcated opacities and 7.2% with extractions due to hypo-mineralization[18]. However, the inability to examine the required sample size calculated for the estimation of the prevalence of DMH due to feasibility issues and a high caries experience amongst the children that may have masked the hypo-mineralization defects could have lead to an underestimation of the prevalence of DMH in this study.

A self-reported pre-pregnancy BMI(Table-4) was used as a surrogate measure for maternal nutritional status. Majority of mother's were found to be underweight prior to pregnancy in this study. A low BMI signifies underweight mothers indicating lack of nutrients which would result in diminished fetal growth or duration of gestation resulting in pre term birth (PTB) and low birth weight (LBW). BMI has greater influence on PTB and LBW (predisposing to EHP) than the amount of weight gain during pregnancy [20]. A large number of adolescent pregnancy cases were observed amongst children with HAS-ECC in this study which is supported by studies among Spanishchildren[21] and Brazilianchildren[22].

A large proportion of mothers in the present study were found to be tobacco chewers during pregnancy. Tobacco consumption by mothers during pregnancy has been associated with increased risks for ectopic pregnancy, still birth, preterm birth. LBW according to a report published in 2013 by W. H. O[23] results in a disequilibrium which affect early events in tooth development such as papilla condensation, enamel organ proliferation PTB has been associated with impaired calcium metabolism and rate of enamel matrix formation as supported by Chowdhury and Bromage[24].

Birth weight less than 2500 grams is being defined as LBW by UNICEF[25] and they may present with neonatal complications and metabolic disorders which may interfere with odontogenesis. A large proportion of children diagnosed with HAS-ECC in this study had low birth weight while Australian Aboriginalchildren[26] with EHP presented positive findings of LBW.

Criteria prescribed by WHO[10] which defines preterm birth as babies born alive before the completion of 37 weeks of pregnancy was used in the present study. PTB has been associated with impaired calcium metabolism which may affect enamel development[27]. History of recurrent diarrhoea was recorded as it would lead to defective mineral absorption or excess excretion of minerals leading to DDE/EHP.

Postnatal malnutrition leads to development of EHP. Postnatal malnutrition upto one year of age leads to EHP in primary dentition since the enamel formation gets completed in the first year of life. Hence, Malnutrition during these growth years may predispose to enamel defects leading to caries. 33% of children presently had moderate malnutrition. A longitudinal study conducted amongst Mexican children revealed an association between malnutrition and development of hypoplastic defects in permanent teeth. [28]. HAS-ECC has been proposed to be a duality of EHP due to systemic insults and cariogenic dietary practices[3] hence, cariogenic dietary practices of the children diagnosed with HAS-ECC were assessed.

The study had certain limitations, ie., the underestimation of the prevalence of HAS-ECC and DMH as they were masked by high caries experience, recall bias amongst mothers of children diagnosed with HAS-ECC while conducting questionnaire based interviews, inability to examine a huge sample may have led to underestimation of the prevalence of DMH.

Conclusion

S-ECC, h AS-ECC and DMH were identified to be present amongst the anganwadi children in West zone of Pune, Maharashtra. Thus, this study reflects the prevalence, clinical presentation (staging) and the probable distinct etiology of the proposed subset of S-ECC defined as HAS-ECC. This is a cross-sectional study hypothesizing the proposed definition and distinct dual etiology of HAS-ECC. Dentistsalong with other health workers should incorporate antenatal and postnatal health education in general and oral health education. It is necessary for the dentists to have adequate knowledge about the etiology of Developmental Defects of Enamel in order to gain a greater understanding of the problem to establish appropriate preventive and curative measures.

Effect of Cold Needle on Pain of Infant After Intramuscular Vaccine in Selected Hospitals

Mary Ajith[1], Rupali Salvi[2], Nisha Naik[3], Vimala Thomas[1], Shweta Joshi[4]

[1]Clinical Instructor, [2]Principal, [3]Asso-Professor, [4]Professor, Dr. D. Y. Patil University, Pimpri, Pune-18

Abstract

Background: Pain is an unpleasant sensory and emotional experience.[1] The pain associated with immunization is a source of anxiety and distress for the children approximately 77.2% of rural and 80% of urban children are immunized annually.[9] Using cold needle would decrease the pain.

Objectives: The objective of the study is to assess the effect of cold needle on pain of infant after intramuscular vaccine.

Materials and Method: An evaluative study with quasi experimental posttest only design was used to assess the effect of cold needle on pain of infant after intramuscular vaccine. 60 samples were taken using probability sampling technique-systematic random from selected hospitals, of which 30 were using normal room temperature needle and 30 were using cold needle. The data was collected using self-structured demographic data, FLACC pain assessment scale and observation checklist.

Results: The analysis was done by using descriptive and inferential statistics. Researcher applied Unpaired t-test for comparison of difference between post- test levels of pain associated with intramuscular immunization among children in experimental and control group based on observational checklist. On observation, Majority of infant 63% experience moderate level of pain during intramuscular injection with cold needle, 23% of the infants had mild pain and least percentage of 13% of the infant had severe pain in experimental group. In control group most of the samples had severe pain i.e. 70% and 30% had moderate level of pain during intramuscular injection. Corresponding p- value was 0.00001 which is significant less than $p<0.05$ level. Hence, the null hypothesis is rejected. It is evident that the use of cold needle is effective.

Conclusion: The intramuscular route is always a preferred one for the delivery of injections. The proper administration of intramuscular injection is necessary to minimize the pain and discomfort. In the present study sufficient difference in pain levels were found. Cold needle was effective in reducing pain during intramuscular immunization in infants.

Introduction

Pain is an unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage.[1] The intramuscular injection is a procedure commonly performed by nurses and are associated with discomfort, pain and trauma to the injected tissue. Even though it can cause tissue, musculoskeletal and neurological complications such as abscess, tissue necrosis, muscle damage and nerve injury.[4]

The pain associated with immunization is a source of anxiety and distress for the children. The Centre for Disease Control and Prevention schedule recommends

immunizations against 16 diseases, which translates in to 16 to 20 separate injections before the age of 2 years, depending on the number of combination vaccines available.[17]

The intramuscular injection is always a preferred one for the delivery of injections and it also causes pain and discomfort. Hence, there are many non-pharmacological measures to reduce the level of pain; one of which is ice-application.[15]

Cold therapy is one of the most widely used treatment modalities for acute pain. The Gate-Control Theory stimulated by cold can close the neural gate so that the central perception of pain is reduced.[7]

Thus, considering the anxiety and pain during the intramuscular injection, the researcher felt the need to conductive an evaluative study on assessing the effect of cold needle on pain.

Method and Materials

Study Objectives:

1. To determine the effect of cold needle on the pain level of children.
2. To determine the association of pain level with selected demographic variables

Study Design: The study used evaluative approach with quasi experimental posttest only design was used to assess the effect of cold needle on pain of infant after intramuscular vaccine. 60 samples using probability sampling technique-systematic random from selected hospitals, of which 30 were using normal room temperature needle and 30 were using cold needle. The data was collected using self-structured demographic data, FLACC pain assessment scale and observation checklist.

Findings:

Section I: Data on demographic variables of immunized infants.

Majority of samples in both experimental and control group belongs to the age group of 1.5 to 3 months i.e. 93% in both experimental and control group. Maximum samples in both experimental and contol group were male i.e. 57% and 63% respectively. Most of the sample i.e. 93% in experimental group and 83% in control group weighted between 4.6 – 5.5 kg . None of the sample had allergy reaction due to intramuscular injection.

Section II: Data on level of pain associated with intramuscular immunization among infants.

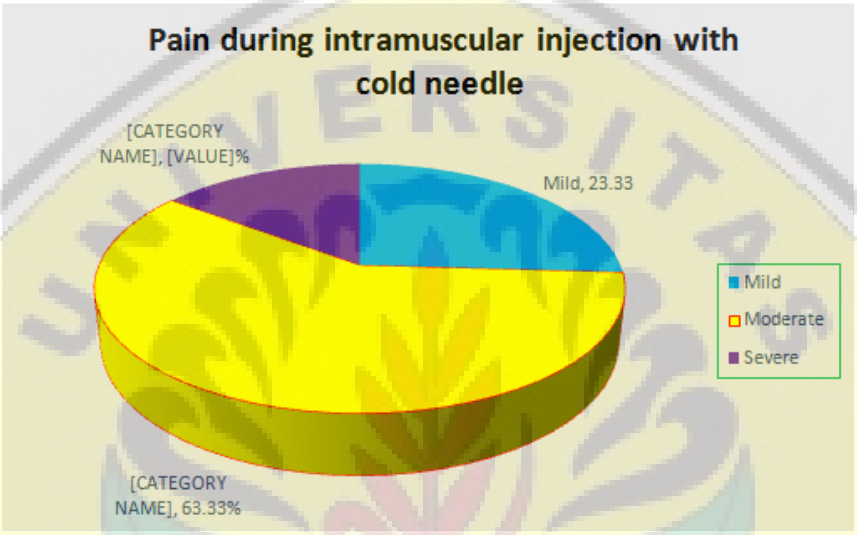
Table 1: Description on level of pain response in the experimental and control group. N=6

Sr.No.	FLACC SCALE (Face, Legs, Cry, Activity, Consolability Scale)	Experimental		Control	
1.	**Face**	F	%	F	%
	No expression or smile	06	20	0	0
	Rarely grimace, withdrawn and disinterested	09	30	3	10
	Persistently quivering chin and clenched jaw	15	50	27	90
2.	**Legs**				
	Normal position	01	3.33	0	0
	Anxiety, restless, stress	25	83.33	12	40
	Legs drawn up	04	13.33	18	60
3.	**Activity**				
	Lying quietly and normal position	01	3.33	0	0
	Squirming, shifting, moving constantly	28	93.33	24	80
	Arched, stiff, jerking	01	3.33	06	20
4.	**Cry**				
	No cry	04	13.33	0	0
	Moan, occasional complaint	22	73.33	20	66.6
	Crying, screams and frequency complaints	04	13.33	10	33.33
5.	**Consolability**				
	Relaxed and pleased	04	13.33	0	0
	Reassure easily by touching and hugging	24	80	19	63.33
	Difficult to pacify	02	6.66	11	36.66

The table no 1 shows that, control group (90%) had constant quivering chin and clenched jaw as compared to experimental group (10%). Majority of infants in experimental group experience uneasiness, restless and tense whereas control group showed kicking of legs i.e. 60%. Both the experimental and control group had squirming, shifting, back and forth tense i.e. 93% and 80% respectively. Most of the infants occasionally whimpers or moans in both experimental (73%) and control (66%) groups. Least percentage of infants had difficulty to console in experimental group i.e. 6% contrast to control group (37%).

Section III: Data on effectiveness of cold needle on levels of pain associated with intramuscular immunization among infants.

Analysis of data to determine the level of pain among infants during intramuscular vaccine with cold needle in experimental group



The level of pain during intramuscular vaccine with cold needle in experimental group.

The majority of 63% of the infant experience moderate level of pain during intramuscular injection with cold needle, 23% of the infants had mild pain and least percentage of 13% of the infant had severe pain.

Analysis of data to determine the level of pain among infants during intramuscular vaccine in control group: The above figure shows that in control group most of the samples had severe pain i.e. 70% and 30% had moderate level of pain during intramuscular injection.

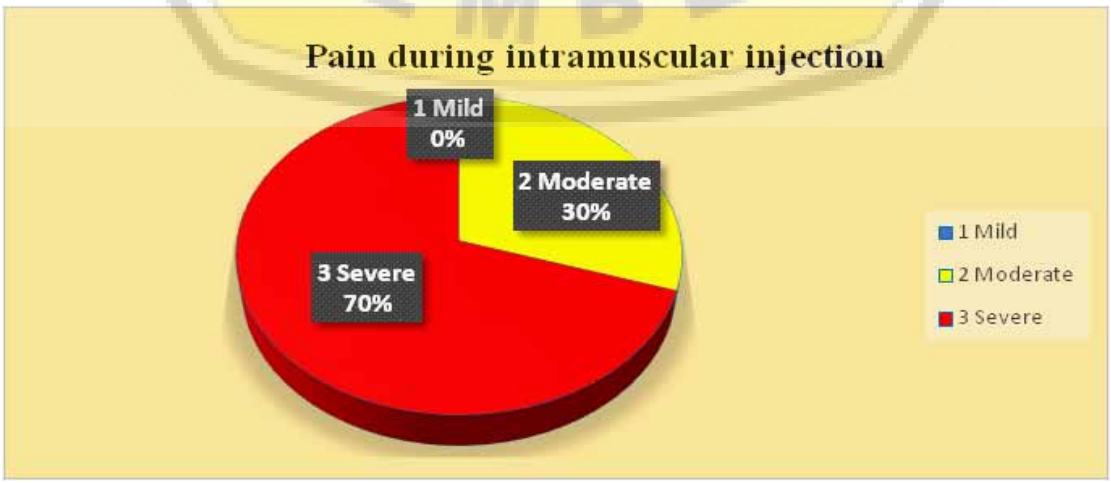


Table No 2: Description on the comparation of level of pain in the experimental and control group. n=30

Sr.No	Level of pain	Mean	Mean difference	Standard deviation	Unpaired t-test	p-value
1	Experimental Group	5.36	2	1.54	5.3423	0.00001
2	Control Group	7.36		1.351		

Researcher applied unpaired t – test to compare the pain during intramuscular injection in control and experimental group. It was found that the mean experimental group score was 5.36 and the mean control group score was 7.36 with the standard deviation of 2. The calculated mean difference was 2 and the obtained 't' value 5.3453 and p- value was 0.00001 which is significant less than $p<0.05$ level. Hence the null hypothesis is rejected. It was inferred that there is a significant difference between mean post- test levels of pain associated with intramuscular immunization among infants in experimental and control group. Cold needle is significantly effective in reducing the pain during intramuscular injection in infants.

Discussion

Present study was done on 60 patients, to assess the effect of cold needle on pain in infant. The sample were divided in two groups, 30 patients using room temperature needle and 30 patients using cold needle.

The focus of this study was to assess the effect of cold needle on pain among infants. In experimental group unpaired t test was applied to compare pain during immunization among infants and the t-value was found to be 5.34 and corresponding p-value was 0.00001, which is less than 0.05, null hypothesis was rejected and research hypothesis was accepted which show that use of cold needle for intramuscular injection is effective. When the samples of experimental and control group were assessed 13% of infant had severe pain in experimental group and in control group 70% of children had severe pain during intramuscular injection, which shows that use of cold needle while intramuscular injection is found to be effective among infants.

The demographical variable has no significant association with pain during Penta vaccination because the p–value is large (greater than 0.05). This data gives sufficient difference in pain levels when compared against experimental and control group. Cold needle was effective in reducing pain during intramuscular immunization in infants.

Conclusion

The purpose of the study was to assess the effect of cold needle on pain of infant after intramuscular vaccine. The research was a learning experience for the investigator which gave her better exposure. In this study since the ($p<0.05$) H_0 (null hypothesis) was rejected. It is evident that the control group had moderate pain as compared to another group. Researcher recommended to use cold needle for intramuscular injection across the hospitals.

Exploring Challenges of Maternal Healthcare Utilization in Bangladesh: A Cross-sectional Survey in Saturia, Manikganj District

Masum Billah[1], Sifat E Sultana[2], M.H.M. Imrul Kabir[3]

[1]Senior Lecturer, Department of Sociology, East West University, Dhaka, Bangladesh, [2]PhD Student, Department of Sociology, University of Saskatchewan, Canada & Senior Lecturer, Department of Sociology, East West University, Dhaka, Bangladesh, [3]Senior Lecturer, Department of Mathematical and Physical Sciences, East West University, Dhaka, Bangladesh

Abstract

The main objective of the study is to explore maternal healthcare utilization challenges and care seeking behavior among child bearing mothers in Bangladesh. A semi-structured interview schedule was utilized for household survey in the study. A total of 240 women with a child under five years from different households were independently selected and interviewed to collect data. Results showed that around 50 percent women experienced cesarean delivery for last childbirth;the rates for ANC and PNC utilization were reported to be 75 percent and 25 percent respectively for the respondents. ANC and modes of latest childbirth were found statistically significant for age of the respondent, level of education and monthly household income.

Keywords: *Maternal Healthcare; ANC; PNC; Cesarean Delivery; MMR.*

Introduction

As a public health priority, maternal healthcare utilization attained enormous importance to reckon with improved healthcare delivery and quality services in Bangladesh. Despite remarkable successes in MDGs associated targets, there is still a continuous disparity in maternal healthcare utilization among Bangladeshi women. Maternal healthcare utilization operated on the basis of supply oriented approach[1] rather than emphasizing socio-cultural factors related with proper access and use of care services. The global health provision SDG 3 attempts to achieve global Maternal Mortality Ratio (MMR) less than 70 per 100, 000 live births by the end of 2030.[2] The main objective of SDG 3 denotes sustainable development attained through universal coverage of health interventions and care services.[1] It seems to be quite questionable to target the achievement of universal maternal healthcare coverage if inequity appears directly in the system. The current health system prioritized to achieve targeted SDG criteria in quantity without reducing gap for quality healthcare.

Maternal mortality, the death of a mother during pregnancy periods or within forty-two days of termination of pregnancy, from any cause related to or aggravated by the pregnancy or its management[3] achieved priority[4] for worldwide health and community development since the Nairobi Safe Motherhood Conference in 1987.[5] Despite huge concentration and financial investment towards maternal and child health, there is still a sharp increase in neonatal, infant and child mortality in sub Saharan Africa and Southern Asia.[5] Bangladesh achieveda surprising success to reduce maternal mortality in the past decade, but there is an indisputable question to decrease MRR target of 121 per 100,000 live births by 2022.[6] MMR found a significant declination from 322 to 194 maternal deaths per 100,000

live births between BMMS 2001 and BMMS 2010[6] in Bangladesh. However, fertility contraction, increased access to healthcare, healthcare in antenatal, delivery and postpartum periods and socioeconomic conditions[6] directly declined maternal mortality. Nevertheless, MMR stopped to get less after 2010 and challenged the achievements of baseline targets of the fourth Health, Population and Nutrition Sector Program [HPNSP] backed by Sustainable Development Goals (SDGs).

Pregnancy related complications are attributable to lead the causes of maternal mortality and morbidity in Bangladesh. Antenatal care (ANC) is identified as an important contributor[7] to diagnose pregnancy complications during child bearing periods. According to BMMS survey (2016), approximately 75 percent women met with a medically trained healthcare provider for at least one ANC visit while around 09 percent women approached a non-medical professional for the same visit. However, 37 percent women accepted the recommended number (4 or more) antenatal checkups during pregnancy in 2016 whereas 23 percent women received four or more ANC checkups in 2010.[6] In a study of 2003, about 53 percent study women did not take any antenatal care check-up and only 11 percent women got a minimum of four check-ups.[8] Moreover, family income, age, education, occupation of both parents [9], mode of transport[10] cost concern for medical treatment[11] and exposure to mass media[12] were found strongly associated with the use of ANC among women during pregnancy periods.

The prevalence of home delivery coupled with low utilization of birth attendant significantly increased maternal mortality in Bangladesh. Although there is a strong mandate to train and employ skilled birth attendants[1] in health facility centers, the utilization of SBAs found disproportionate prevalence in different wealth settings.[13,14] The existing literature validated that around 85 percent Bangladeshi women accepted home delivery from untrained birth attendants like neighbors or relatives with nomedical or facility training.[15] In Bangladesh, out of 80 percent respondents, over 70 percent mothers considered home delivery as comfortable while about 29 percent respondents claimed it as obligations due to family sentiments and financial constraints.[16] PNC associated physical examination, immunization, health education and family planning services[9] improved maternal healthcare. Despite progress, there was also a low level of skilled PNC visits[1] within two days of delivery among Bangladeshi mothers.[17] The main objective of the study is to correlate socio-economic variables of women with maternal care-seeking behavior and explore maternal healthcare utilization challenges in Bangladesh.

Method

A descriptive cross-sectional survey was administered to collect quantitative data about ANC, PNC and birth attendant for March-April, 2018 at Saturia village in Saturia upazila, Manikganj. Women who had given birth in the last five years and her child remained alive were contacted with the interview. The study purposively selected Saturia village from nine villages in Saturai upazila. Every household was chosen using simple random sampling to get a woman with a child under five years old. A total of 240 women from different households were independently selected and interviewed to collect data. A semi-structured interview schedule was utilized for the survey. The interview schedule was translated into Bengali to facilitate comfortable interview session with local women. The data collection team composed of both male and female interviewers. Data captured into individual interview schedule was entered into database created by SPSS software and cleaned simultaneously. Data analysis was performed by using the Statistical Package for the Social Sciences (SPSS) software (version 20). The status of data analysis appeared descriptive in nature.

Findings:

Table 1: Birth attendant of mothers

Characteristics	Frequency	Percent (%)
Mode of latest delivery		
Cesarean	123	51.3
Normal	117	48.8
N	240	100.0
Decision makers about latest delivery		
Self-decision	37	15.42
Husband	53	22.08
In laws	13	5.92
Parents	22	9.17
Doctors	44	18.33
Nurses	2	0.83
Family after the discussion	60	25.0
Others	9	3.75
Total	**240**	**100.0**

Place of delivery		
Home	69	28.8
Public hospital or clinic	46	19.2
Private hospital or clinic	125	52.1
Total	**240**	**100.0**
Decision makers about place of latest delivery		
Self-decision	29	12.08
Husband	60	25.0
In laws	12	5.0
Parents	34	14.17
Doctors	16	6.67
Nurses	3	1.25
Family after the discussion	66	27.5
Others	20	8.33
Total	**240**	**100.0**

In the Table 1 it was noted that approximately 50 percent mothers accepted cesarean method during their last child birth whereas around 48 percent mothers sought for normal delivery. However, family after consultation (25.0 percent) and hus Bands (22.08 percent) appeared as dominant factors that determined the delivery. Moreover, about 18.33 percent doctors suggested the latest delivery type for mothers while around 15.42 percent respondents decided by themselves. About 71 percent mothers got delivered at public or private health centers by a trained staff while around 29 percent respondents sought home delivery by a traditional birth attendant. It was noted that family decision after the discussion (27.5 percent) and hus Band's decision (25.0 percent) were found as contributory factors to select place of delivery.

Table 2: Antenatal care seeking practices and challenges

Characteristics	**Frequency**	**Percent (%)**
ANC for last pregnancy		
Yes	167	69.58
No	73	30.42
Total	240	100.0
Frequency of ANC care		
One	38	22.75
Two	39	23.35
Three	32	19.16
Four +	58	34.73
Total	**167**	**100.0**

Public health centers	69	34.2
Traditional healer	5	2.5
Homeopathic shop	3	1.5
Local pharmacy	16	7.9
Total	**202**	**100.0**
Challenges for ANC*		
Lack of money	61	57.0
Excessive costly	5	4.7
Long distance	1	.9
Lack of companion	6	5.6
No permission from husband	7	6.5
No permission from family	27	25.2
Total	**107**	**100.0**

*Multiple Responses

Overall, about 70 percent mothers sought for ANC service during last pregnancy whereas around 30 percent survey respondents did not seek for ANC. Approximately 35 percent mothers sought ANC service for four times or more followed by WHO guidelines. In order to seek ANC services, 54 percent of the study mothers found private hospitals while around 34 percent got in public hospitals during last pregnancy. Around 57 percent study mothers claimed lack of money while about 25 percent study participants expressed they did not get any permission from family for ANC.

Table 3: Postnatal care seeking practices and challenges

Characteristics	**Frequency**	**Percent (%)**
Postnatal care for last pregnancy		
Yes	59	25.3
No	174	74.7
Total	**233**	**100.0**
Frequency of postnatal care

Two	16	27.11
Three	11	18.64
Four +	8	13.56
Total	**59**	**100.0**
Postnatal care seeking practices*		
Private health centers	85	61.6
Public health centers	32	23.2
Traditional healer/Quack	6	4.3
Homeopathic shop	4	2.9
Local pharmacy	11	8.0
Total	**138**	**100.0**

Characteristics	Frequency	Percent (%)
Challenges for PNC services*		
Lack of money	27	19.6
Excessive costly	4	2.9
Long distance	3	2.2
Transportation problem	4	2.9
Lack of companion	6	4.3
No permission from husband	12	8.7
No permission from family	82	59.4
Total	**138**	**100.0**

*Multiple Responses

In the table 3, survey results demonstrated approximately three quarters (75 percent) child bearing mothers did not seek for any postnatal care whereas one quarter (25 percent) respondents sought for postnatal care after the last delivery. In addition, around 40 percent mothers received PNC service for one time while about 25 percent respondents accepted PNC service for two times. Approximately 60 percent of the study mothers claimed about no permission from family as the major challenge for PNC coverage whereas around 20 percent study participants reported scarcity of money as barriers to PNC.

Table 4: Table on socioeconomic and maternal healthcare variables

Characteristics	Sources of PNC	ANC seeking	Mode of last childbirth	Place of last delivery
Age	$\chi^2 = 4.437$ P = 0.079	$\chi^2 = 4.302$ P = 0.038*	$\chi^2 = 4.09$ P = 0.043*	$\chi^2 = 9.36$ P = 0.009**
Education	$\chi^2 = 7.47$ P = 0.053*	$\chi^2 = 6.34$ P = 0.029*	$\chi^2 = 5.91$ P = 0.047*	$\chi^2 = 6.708$ P = 0.037*
Income	$\chi^2 = 5.07$ P = 0.065	$\chi^2 = 5.25$ P = 0.032*	$\chi^2 = 5.983$ P = 0.043*	$\chi^2 = 8.586$ P = 0.032*

* Significant at = 5%, ** Significant at = 1%

Age and monthly income of respondents and sources of PNC remained statistically independent. Age and monthly income of the household did not influence selection of PNC sources. On the other hand, ANC uptake and modes of latest childbirth were found statistically significant for age of the respondent, level of education and monthly household income.

Discussion

Unlike scientific and legal[18] provisions, normal delivery appeared as surgical and medical intervention that seriously stroke mothers. Having CS not more than 10-15 percent, [19] the state of CS culminated in developing countries like Bangladesh. The current study showed over 51 percent mothers opted for cesarean delivery while about 49 percent respondents reported it normal. Unlike 10-15 percent accepted by WHO, the rates of CS in Bangladesh (51.3 percent) doubled compared with that of USA (24 percent), UK (22 percent) and Brazil [30 percent in public hospitals and 70 percent in private hospitals], the world highest cesarean rates.[2] Likewise, Bangladesh stepped into CS for mothers due to multiple factors. Skilled birth attendants emerged as significant contributors for safe delivery during pregnancy, child birth and their immediate postnatal periods.[21] However, over 71.3 percent respondents went to public or private hospital or clinic for their recent child birth while about 29 percent respondents experienced home delivery attended by a traditional birth attendant. The current findings contrasted that picked up about 49.2% deliveries were attended by traditional birth attendants in Bngladesh.[16]

About 70 percent mothers experienced ANC services while around 30 percent mothers did not receive any ANC check-up for their recent child birth. These results similarly matched with that of another study in Bangladesh, the percentage of ANC uptake and ANC negligence appeared as (76.8 percent and 23.2 percent) respectively in 2016.[22]

Age, maternal education and monthly household income showed a significant association with ANC of women in Bangladesh. The findings agreed to results of BDHS 2014 in Bangladesh. Additionally, a significant

increase of adequate ANC visits among pregnant women was observed with the increase in maternal education level.[23] In case of PNC analysis, the current study picked up the reverse maternal health outcome. Majority of the mothers (74.7 percent) did not receive any post-natal care after delivery in the current study while only 25.3 percent respondents experienced PNC care in post-delivery periods. The notable challenges women encountered lack of family permission (59.4 percent) and financial constraints (19.6 percent) to seek for PNC services in the region.

Conclusion

Family and hus Band appeared as the dominant actors to shape birth attendant choices of mothers in Bangladesh, though there are plenty of challenges to achieve ANC and PNC outcomes suggested by WHO in rural context in Bangladesh. A comprehensive maternal and child health policy coupled with an active healthcare facility might be recommended to advance maternal and child friendly healthcare environment.

Conflict of Interest: None declared

Financial Disclosure: None declared

Ethical Clearance: The study was operated at Saturia, Manikganj, Bangladesh by taking official approval of the director of Saturia Health Complex. Moreover, the study sought for individual consent to collect survey data in person.

Abstract

Background: Drug utilization study are used to foster more efficient use of scarce resources to improving the standards of medical treatment at all levels in health system. It also helps in the identification of problems created with drug use. The aim of study was to evaluate the pattern of drug utilization of antibiotics in patients.

Method: This was a prospective observational study which was done in six months from August 2018–February 2019. 100 patients were enrolled in the study. Which were taking antibiotics from in-patient department of medicine ward of tertiary care teaching hospital. Results: It was observed that out of 100 patients, 52 were female and 48 were males. Majority of the patient lies in the age group of 20-40 years. It was observed that total 623 drugs were prescribed out of which 146 were antibiotics (23.43%). The use of these antibiotics was in intravenous (87) and oral (59). There were 78 conditions in which antibiotic were prescribed empirically and in 22 conditions prophylactically. The maximum antibiotic prescribed was observed in Urinary Tract Infection (20.51%). Major cost was rendered by Cephalosporin class (36.98%) and the least was of tetracyclines (2.05%). The ratio of cost of total drugs to the antibiotics was found to be 49.37%.

Conclusion: Thus the study conclude that the Drug Utilization Study can help to understand the usage pattern and extra cost rendered by the patient due to intravenous antibiotic and thus providing a helping hand in the designing of antibiotic policies.

Keywords: *Antibiotic, Drug utilization study, Antibiotic usage pattern.*

Introduction

In contrast to the public health, resistance of antibiotic becomes a major threat as the consumption of antibiotic increases[(1)]. Antibiotics-resistant pathogens have become evident and spread among human and animal populations worldwide[(2,3,4)]. Pathogens such as methicillin-resistance staphylococcus aureus (MRSA)[(5)] and carbapenem-resistant Enterobacteriaceae (CRE)[(6,7)] have become a worldwide problem. The loss of efficacy against common pathogens has not only led to a shift towards extortionate antibiotic drugs in high-income countries, but also to increased morbidity and mortality in low-income and middle-income countries, where it restricts their use due to afford ability of second line drugs[(8)]. An inappropriate prescription increases the cost of the medical treatment and it also increases the morbidity and mortality. The impact of the irrational prescription of drugs also leads to an increase in

Tel.: +91-7017548594

the incidence of adverse drug events. To control the worldwide ascendancy of bacterial resistance, to minimize the side effects and to reduce the cost of the treatment, the rational use of antibiotics is being increasingly recognized as an important contributor[9].

In recent years, issues of quality assurance and cost control have often focused on the use of antibiotics [10, 11]. This has led to the broadcasting of antibiotic utilization review which is an authorized, structured, ongoing review of prescribing, dispensing and use of medication. Antibiotic utilization review results are used to foster more efficient use of scarce health care resources. It provides opportunity to identify trends in prescribing within groups of patients whether by disease-state or drug-specific criteria[12,13,14,15].

So this study was undertaken in an active inpatient environment of tertiary care teaching hospital to evaluate the usage pattern of intravenous and oral antibiotics, to assess the additional cost rendered by the patients due to over utilization of antibiotic and drug related problems evaluation associated with the antibiotic.

Study Design: A prospective observational study on antibiotic utilization pattern was conducted by the department of pharmacy practice in collaboration with M. M. Hospital, mullana-ambala (India) with a sample size of 100 patients. The study was conducted for a period of six months from August 2018 to February 2019. A total of 100 patients were analyzed on the basis of inclusion and exclusion criteria. All the prescription had complete documentation of information including, patient demographic characteristics, date of admission and discharge, clinical diagnosis, drug name, dose and route of administration, investigations, rationality and outcome of health status. The data of the patients who received antibiotic was recorded and analyzed further for drug utilization studies. The study protocol and all the other documents which were related to the study were approved by the Institutional Ethics Committee.

Inclusion Criteria: All the patient of either gender with any kind of diseased condition admitted in medicine ward of M.M. hospital during the study period were included in the study.

Exclusion Criteria: We excluded the inpatients who discharged on the day of admission, outpatient and patients admitted to ICU. All the pediatrics, geriatrics, pregnant/lactating mothers were also excluded in the study.

Method of Data Collection

During our study, we reviewed the case record sheets of all patients who met the inclusion criteria. Data was collected using a well-structured case record form (CRF) which includes patient's demographics, drug allergies, patient's disease history, medication chart, culture reports and laboratory parameters. The culture and sensitivity reports were analyzed to assess the appropriateness of the antibiotic selection. Any medication error and drug related problems that were found in our cases were also recorded. All the discrepancies observed have been documented appropriately in the CRF designed for our study.

Results

A total of 100 patients were enrolled in the study from August 2018 to February 2019. The subjects were segregated into 5 major groups as discussed in table 1. The mean age of the subjects was found to be 38.97 ± 19.70 years. It implies that the maximum patients were in the age group of 20 – 40 years with standard deviation of 19.70 years. Moreover, it was observed that male-female ratio almost equal, contributing to 1:1.1(48; 52). The mean age of male population was observed as 39.09 ± 19.67 years whereas; in female population it was found to be 38.98 ± 19.70 years. This implies that the majority of male and female patients were from the age group of 20 – 40 years.

It was observed that, majority of the subjects are from the age group of 20-40 years with 17 males and 21 females patients, followed by the patients under 41-60 years (29 Females; 11 male) shown in figure 1.

Antibiotics were the most used drug along with anti-tubercular drugs and anti-malarial drugs (n=146; 23.43%), followed by antacids (n=100; 16%), utilization of multivitamin and supplements was less (n=78; 12.52%), followed by NSAIDS (Non-steroidal Anti-inflammatory drugs) (n=70; 11.23%). (table 1).

The comorbid conditions of the subjects (n=100) were classified into three types. Patients with one morbidity was the highest (n=49), followed by the patients with two comorbid conditions (n=31) and the patients with more than two comorbidities was the least (n=20).

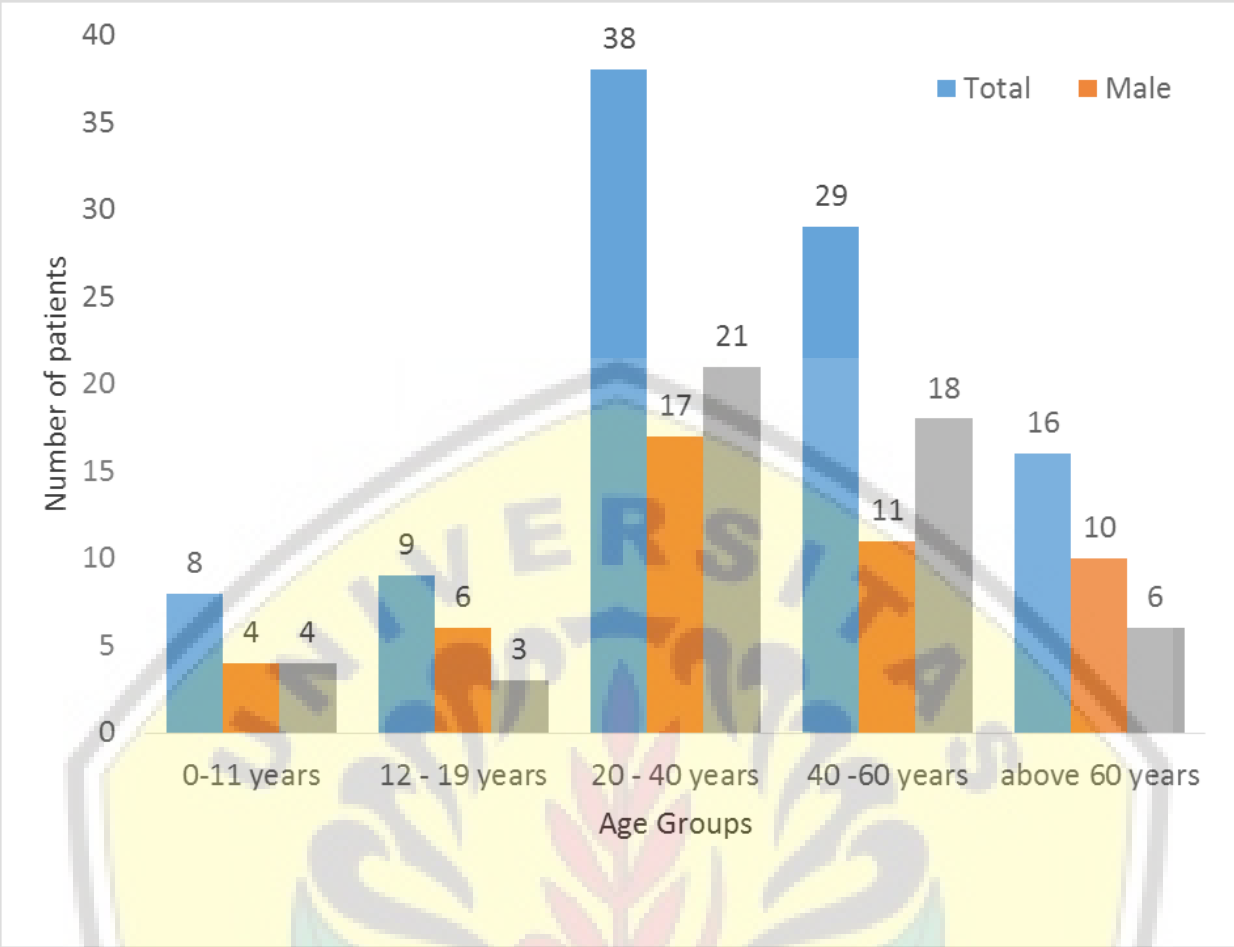

Figure 1: Gender wise age-distribution

Table 1: Antibiotic usage pattern

Medication class	Total number (n)	Percentage
Antacid	107	17.17%
Anti-allergic	13	2.09%
Anti-anemic	7	1.12%
Antibiotic	146	23.43%
Anti-emetics	47	7.54%
Anti-epileptic	20	3.21%
Anti-hypertensive	27	4.33%
Anti-thyroid	5	0.8%
Anti-viral	1	0.16%
Hypoglycemic	8	1.28%
Hypolipidemic	3	0.48%
Laxatives	21	3.37%
Multivitamins & supplements	78	12.52%
NSAIDS	70	11.23%
Others	45	7.22%
Probiotics	8	1.28%
Steroids	15	2.4%
Vaccine	2	0.32%

Table 2: Pattern of antibiotic usage in various systemic conditions

Systemic conditions	Total drugs (n1)	Antibiotic (n2)	Percentage (n2/n1)
Infectious	263	62	23.57
Gastro intestinal	147	37	25.17
Renal	56	11	19.6
CNS	47	10	21.27
Reproductive	41	11	26.82
Respiratory	37	10	27.25
CVS	14	2	14.28
Hematologic	10	1	10
Musco-skeletal	5	2	40

There were total 78 conditions in which antibiotics were prescribed empirically and 22 conditions in which antibiotics were prescribed prophylactically. The antibiotic count was maximum in Urinary tract infection (UTI) (n=16, 20.51%) following hepatitis (n=14; 17.94%), fever (n=12; 15.38%), dengue (n=7; 8.97%), pneumonia (n=6; 7.69%), cystitis (n=5; 6.41%), psoriasis (n=4; 5.12%), sinusitis (n=3; 3.84%), malaria (n=3.84%) and scabies (n=2; 2.56%). (Table 2)

Table 3: Various infection conditions

Infection condition	Total number (n)	Percentage
UTI	16	20.51
Hepatitis	14	17.94
Fever	12	15.38
Dengue	7	8.97
TB	6	7.69
Pneumonia	6	7.69
Cystitis	5	6.41
Psoriasis	4	5.12
Sinusitis	3	3.84
Malaria	3	3.84
Scabies	2	2.56

It was observed that, a total of 11 different antibiotic classes were used during the study. A major proportion of the antibiotics involved the usage of cephalosporin (n=54; 36.98%) (Table 3).

Table 4: Various classes of antibiotic used

Antibiotic	Total number (n)	Percentage	Cost
Cephalosporin	54	36.98	8894
Fluroquinolones	22	15.01	4403
Penicillin	16	10.95	3329
Beta-lactams	10	6.84	3304
Aminoglycosides	9	6.16	2250
Macrolides	9	6.16	1376
Nitroimidazoles	8	5.47	1260
Nitrofurantoin	7	4.79	451
Tetracycline	3	2.05	438
rifaximin	3	2.05	2347

The cumulative cost of 623 drugs was found to be INR 64,573. The average cost of total drugs was found to be INR 443 with a quartile range of 322.5-601 INR. The cumulative cost of 146 antibiotics was observed as INR 25,705. The average cost of antibiotic was found to be INR 224 with the quartile range of 144-288 INR. The ratio of cost of total drugs to the antibiotics was found to be 49.37% of total cost of the medication of a single patient was spent on antibiotic itself. Thus it was clearly evident that, a major portion of the medication cost comprises of antibiotics (Table 4).

Discussion

As India, the most populous country in the world, with over 1.21 billion people (2011 census), India houses more than a sixth of world's population. Already containing 17.5% of the world's population, India is projected to be the world's most populous country by 2025, surpassing China, with its population reaching 1.6 billion by 2050. India has more than 50% of its population below the age of 25 and more than 65% below age of 35. The life expectancy level has been improving over these decades for both male and female population[16]. The improvement among female is better than male population [17, 18]. Sex ratio has improved from 930 in 1961 to 940 in 2011 which is an appreciable improvement but still below the international levels. The country has a long way to go before attaining the levels achieved by developed countries and many developing countries [19, 20].

A majority of the study subjects were housewives (n= 44), followed by students (n= 27), workers (n=11), businessmen (n=8) and farmers (n=8).

The WHO prescribing indicators provided earlier, gives a comprehensive idea regarding the pattern of antibiotic use in this institution. The overall antibiotic encounter rate as per our study was 23.43%, which is not much different from the WHO standard of 20-26.8%. This is certainly a welcome attitude and could reflect the concern of the practicing doctors for the rapidly spreading bacterial resistance. This is significantly less than the values reported from many other parts of India – (47.6%, 73>1% and 81.8% from T.puram, Chennai, Vellore and Lucknow) respectively [21, 22, 24]. In another study from South India, the percentage of injections was as low as 1.6%. It is a well-accepted fact that parenteral therapy is significantly costlier, because of the higher price for the formulations, the cost of the syringes as well as nursing charges. The significant use of injectable in this institution requires pointed focus for the reduction of use of injectable to deserve appreciation[24].

The selection of individual agents in most instances raises a big question mark on their scientific basis. In our study, there were 78 conditions in which antibiotic were prescribed empirically and 22 conditions in which antibiotic were prescribed prophylactically. Lab reports from microbiology had not been given due to definitive line of management in majority of infections. This also appears to be the situation in many developing countries[25, 26].

The use of tetracyclines, however, was high in the rural hospital setup in the Vellore study.[27,28] Among the newer agents, meropenem, linezolid and tigecycline found only very little usefulness probably due to their high cost and because of exclusion of ICU patients from this study.

Management of infections like Urinary Tract Infection, Upper Respiratory Tract Infection as well as Skin Infection with a single antimicrobial could be appreciated, though this was probably feasible as the involved pathogen could be correctly guessed/ identified[29,30]. In management of Urinary Tract Infection, especially as an empirical therapy, use of flouroquinolones (15.01%) goes certainly against the currently accepted policy. Nitrofurantoin is now considered as the first line agent for treatment and prophylaxis of lower Urinary Tract Infection, based on its proved effectiveness and established safety accrued from its long term use[31, 32, 33]

Conclusion

The study highlighted the usage pattern of antibiotics. The average antibiotics prescribed was found to be low but there was an overuse of intravenous dosage form that had increased the cost of treatment. Also more antibiotic was prescribed based on the empirical therapy followed by the prophylactic therapy. Thus the study conclude that the Drug Utilization Study can help to understand the usage pattern and extra cost rendered by the patient due to antibiotic and thus providing a helping hand in the designing of antibiotic policies.

Abstract

Background: Stroke is a medical emergency and can cause permanent neurological damage. It is defined as the loss of focal neurological function caused due to interruption of the blood flow to the brain.

Objective: To evaluate effect of modified constrained induced movement therapy principles with therapeutic clay moulding exercises on quality of hand function in post-stroke individuals

Method: Ethical Clearance was obtained from Institutional Ethical Committee, KIMSDU, Karad. 42 subjects were selected and were equally divided into two groups. Group A was treated with conventional physiotherapy treatment and Group B was treated with conventional physiotherapy and Clay therapy exercises with modified CIMT principles.

Results : Statistical test was performed using paired test and unpaired test. Pre intervention analysis done for Chedoke Arm and Hand Activity Inventory showed no significant difference with p value= 0.9715, for Box and Block test p value=0.9125. Post interventional analysis done for Chedoke Arm and Hand Activity Inventory showed extremely significant difference, p= <0.0001, for Box and Block test showed extremely significant difference, p value= <0.0001.

Conclusion: The present study concluded that there is a significant effect of modified constrained induced movement therapy principles with therapeutic clay moulding exercises on quality of hand function in post-stroke individuals

Keywords: *Stroke, modified constrained induced movement therapy, Chedoke Arm and Hand Activity Inventory, Box and Block test, Clay therapy.*

Introduction

Definition: Stroke is a medical emergency and can cause permanent neurological damage. It is defined as the loss of focal neurological function caused due to interruption of the blood flow to the brain. Neurological signs/deficit must be present for at least 24 hours to be classified as stroke.[1]

Prevalence: Its prevalence is 84 to 262/1, 00,000 in rural area and 334 to 421/1, 00,000 in urban areas. There are two types of stroke mainly ischemic and hemorrhagic stroke. 1 Stroke is a common neurological conditions affecting 55-75% of upper limb persistent dysfunction. It is a leading cause of death and disability in India .

Clay Therapy: Principles for developing hand

Corresponding Author:
Dr. G. Varadharajulu

manipulative skills are as follows . Somato-sensory stimulus is

Provided[10]. Activities included for sensory awareness are as follows: finding out objects from the beans, sand or rice (finger movements which are graded are used to get grains out of rice or sand can be used off the object), to pull the pieces of clay out of the ball of the clay, by immersing finger and pushing the ball of the clay, by doing the flexion, extension activity of fingers into the clay[2]. Facilitation can be done to gain the function of hand which can be achieved by pulling the clay, facilitation of metacarpophalangeal with interphalangeal extension due to this required action can be gained . Spherical grasp should be emphasized by doing the combine action of long flexor activity and intrinsic activity [2].

ConventionalExercises: Previousstudiesconducted for rehabilitation included mainly conventional exercise which comprises of Positioning, Active and Passive range of motion exercise, Stretching[13] and Mat exercise, Perturbations training, Transfer training and Vestibular ball exercise, Closed kinematic chain exercise, therapeutic gymnasium training, Gait training[14]. Other treatment protocol included electrical stimulation[9], Ice/ Heat therapy as a part of conventional training.

Present studies done for hand rehabilitation compromises of Constrained induced movement therapy, Functional electrical stimulation, Upper extremity task oriented training, stretching and passive exercise . These exercise train the whole upper limb[11].

Constrained Induced Movement Therapy (CIMT): Various studies show CIMT improves upper limb function a cluster randomized controlled trial that examined improving activities of daily living of patients suffering from stroke in primary health care by modified CIMT[8].

Modified CIMT: The original CIMT devotes six or more hours for therapy researchers have observed that such schedule of CIMT is exhaustive and possibly resulting in non -compliance modified shorter version of CIMT has been designed to overcome such limitations. In literature large variety of mCIMT paradigm has reported . Duration of intervention varies from two to ten weeks and treatment time varies from as short as thirty minutes to three hours per day[5].

In this study we have made an attempt to investigate the efficacy of mCIMT principles with clay moulding exercises and comparing its result with only conventional rehab program in terms of quality of hand function[5].

Previous studies showed that hand function can be improved by strengthening exercise as well as electrical stimulation and use of robotics,[3] which work on whole upper limb but there is paucity of hand function training mainly skill full activities like fine movements and gross of hand[11].

Using a therapeutic clay as a part of hand rehabilitation can help in training of gross motor functions as well as fine motor function as it is moldable and can be used in varying sizes[4].

Moreover, the use of clay for hand function rehabilitation may be an interesting, cost- effective method for dexterity training as compared to robotics and other financially challenging technique.

Thus, this study focuses in the aspect of, fine movements as well as gross movement training by the use of application of modified constrained induced movement therapy principles with clay molding exercises on quality of hand function in post stroke individuals[7].

Materials and Method

A total 42 participants with history of stroke willing to take treatment for 4 weeks were recruited for the study. The subjects were screened and were put in either of the groups

Group A received conventional treatment and Group B received conventional treatment and Clay therapy with modified CIMT principles. By consecutive sampling method. A written informed consent was taken from each participant. Ethical Clearance was obtained from University's Institutional Review Board. Inclusion criteria were both male and female subjects between 35-65 years of age, Brunnstrom stage 3 and above, Involved hand Achieved proximal control.

Pre-Test: Chedoke Arm and Hand Activity Inventory was used to assess the Hand Function[6].

Box and Block test was used to assess Grasping Hand function[6].

- The treatment was given for 4 weeks with 5 session per week.

Procedure: The treatment session given with clay therapy is for 4 weeks each exercise had repetitions of 10 times * 3 sets with conventional exercises protocol.

By using consecutive sampling method participants were divided into two groups

Group A: Conventional treatment

Group B: Conventional treatment and Clay therapy with modified CIMT principles.

Conventional Exercises:

1. Passive or active assisted exercises will be given for upper limb
2. Cryotherapy: Icing should be done to the affected spastic muscle group.
3. Stretching: stretching should be given to the affected spastic muscle
4. Mat exercises.
5. Electric stimulation
6. Stretching
7. Weight bearing exercises
8. Ball exercise : Ask the subject to hold the soft ball in hand and perform gripping action.
9. Peg board:
10. Spring exercises
11. Rubber exercise
12. Elastic tubing bands
13. Towel exercise
14. Match stick exercise
15. Exercise on ADL table
16. Functional training:
    a. Lifting an empty glass and keeping on table followed by glass
17. filled with water
    a. Combing hairs.
    b. Holding different sizes of pen and writing.
    c. Dressing and undressing shirt.
    d. Eating activity with spoon .
    e. Lifting large objects to small objects

Group B: All the above mentioned conventional exercises with additional clay exercises.

Clay Exercise:

1. Full grip
2. Finger scissor
3. Finger spread
4. Finger pinch
5. Finger extension
6. Thumb press
7. Thumb extension
8. Thumb abduction

Exercise session were performed for 45 min.

Statistical Analysis: The statistical analysis was done using paired 't' test and unpaired 't' test.

- Paired 't' test was used for statistical analysis of pre and post intervention within group.
- Unpaired 't' test was used for between group statistical analysis of Group A and Group B.

Results

Table No. 1: Post interventional intragroup analysis–Chedoke Arm and Hand Activity Inventory

	Mean±SD	Median	'P'	Inference
Group A	38±21	38	<0.0001	Extremely significant
Group B	64.23±3.632	65		

Table No. 2: Post interventional intra group analysis– Box and Block test

	Mean±SD	Median	'P'	Inference
Group A	30.61904±3.993	31.000	<0.0001	Extremely significant
Groupb	51.4761±7.118	49.000		

1. **Chedoke Arm And Hand Activity Inventory:** In the present study pre interventional mean within group CHAI score was 24.1428+3.953 in group A and 24.1904+5.997 in group B whereas post-interventional mean of CHAI score was 38+8.141 in group A and 64.238+3.632 respectively. Comparison of Pre And Post Values of Chai Scale Between Group Pre interventional mean of CHAI score was 24.142+3.953 in group A and 24.190+5.997 in group B .whereas post interventional mean CHAI score was 38+21 in group A and 64.23+3.632 in group B respectively.
2. **Box And Block Test:** In the present study pre interventional mean within group for BB score was 17+2.702 in group A and 17.0952+2.879 in group B. whereas post interventional mean of BB score was 30.61+3.993 in group A and 51.47+7.118 group B respectively. Comparison of Pre and Post box and block test scores between group study pre interventional mean of BB sore was 17+2.702 in group A and 17.09523+2.879 in group B whereas post interventional BB score was 30.61904+3.993 in group A and 51.4761+7.118 in group B respectively.

Discussion

Stroke is a common neurological condition which affects 55-75% of upper limb persistent dysfunction . It is a leading cause of death and disability in India. Its prevalence is 84 to 262/1, 00,000 in rural area and 334 to 421/1, 00,000 in urban areas. Hand function is an important thing which is needed in day to day life and in stroke survivors it is lost hence to improve it by various treatment strategies this study was conducted. To gain the hand function proximal group of muscles should have proper control, when proximal control is achieved then only hand training can be done.

There are various technique used for training hand function of the studies showed CIMT is beneficial and as on as the concept of training hand function with clay molding exercise is beneficial for all the categories of the people i.e. from rural to urban population, hence the aim of our study was to gain hand function by using modified CIMT principles with clay molding exercise.

Modified CIMT shows Function-induced recovery (use dependant cortical reorganization) refers to the ability of nervous system to modify itself in response to changes in activity and environment. Hand training can be done when the proximal control is achieved as the control is achieved it becomes easier in training the gross motor and fine motor activity, CIMT supports the concept of redundancy.

Clay exercises are mainly used as they are cost effective, it has property of moldability and can also be used for strengthening purpose as it provides resistance. Also clay helps to improve recreational activity which helps in improving the mood of the subjects too, hence the use of clay is done.

In the present study 42 Participants were included according to inclusion and exclusion criteria. . Ethical Clearance was taken prior conducting the study from Krishna institute of medical sciences . An informed consent form was taken from the participants. Further they were classified according to Brunnstrom stages of Recovery as stage 3 and above.

By using consecutive random sampling method participants were divided into two groups: Group A and Group B. There were 21 participants in each group. Participants were assessed by Box and block test Chedoke arm and hand activity inventory. Group A was given conventional physiotherapy and Group B was given conventional physiotherapy with clay moulding exercise using CIMT principles.

The treatment protocol was for 5 days in a week for 4 weeks using Box and Block and Chedoke arm and hand function inventory as outcome measure. After completion of 4 week the outcome measures showed considerable changes. Statistical analysis was done by using instat – graph pad . There was significant difference between the group comparison for Box and lock test with P value of (<0.0001) which suggest extreme significance. The Chedoke arm and hand function inventory also showed extreme significance with p value of (<0.0001)

We have observed the changes in aspect of fine motor as well as gross motor activities like improvement in coordinated movements of hand.

Daily activities like holding a glass of water, transferring of objects, picking up of objects, pouring of water and writing.

In females improvement in wringing, grooming, cooking, household work has been reported.

Self care activities like brushing, combing, dressing, zipping the zip, folding clothes also improved.

Ahmed M Azzam studied and concluded Hand Function training with traditional physiotherapy program should be considered in improvement of hand grip motor control and functional abilities of the hand in hemiplegic cerebral palsy children.

Young-Sil Bae, Ph D, RN and Dong-Hee Kim, Phd, RN studied the effect of clay art therapy and concluded that clay activity can boost self-confidence, increase emotional stability and enhance quality of life for PD patients.

Virgil Mathiowetz, hand motor skills,Occupational therapy, tests studied Adult norms for the Box and Block tests of manual dexterity and concluded the box and block test is a simple low cost and efficient test of gross manual dexterity they suggest that it is a test to evaluate adult individuals with suspected impairmet in manual dexterity .

A. Siebers,U. Oberg, E. Skargren studied The Effect of modified constrained induced movement therapy on spasticity and motor function of the affected arm and concluded that following two weeks of modified CIMT the study found reduced spasticity, increased daily use of affected arm and functional improvement as measured by MAS AROM, grip strength, AL, Solerman hand function test and BBT.

The result imply that, clay molding exercises with principles of CIMT is more effective as Scores also showed highly significant changes in Group B.

This suggests that clay molding exercises with modified CIMT principles is effective in improving hand function in stroke patients as compared to conventional intervention by improving fine motor and gross motor skill full activities. It can be due to specificity of exercise program with property of clay i.e. moldibility that helped in achieving gross and fine motor activity.

Skilled performance is a delayed muscle activity but with added specificity of clay and Modified CIMT principles and variability helping in retention of the skilled activities. This clay molding method is also cost effective which can be beneficial to all the population to get the equal benefit of the treatment. This accounts to better improvement giving additional effect using clay molding exercises with CIMT principle's for hand training as compared to only conventional training.

Conclusion

The present study provided the evidence to support that modified CIMT principles with clay moulding exercise along with conventional physiotherapy has showed improvement in gaining hand function mainly fine motor and gross motor activity.

Conflict of Interest: The author declares that there were no conflicts of interest concerning the content of present study.

Funding: The study was funded by Krishna Institute of Medical Sciences Deemed to be University, Karad.

Ethical Clearance: The study was approved by Institutional Ethics Committee, KIMSDU.

Knowledge on Urolithiasis among Patients Attending OPDs in Selected Hospital of Udupi District Karnataka

Merlin K. Kunjumon[1], Shalini G. Nayak[2], Janet Prameela D'Souza[3]

[1]Second Year M.Sc. (N), [2]Assistant Professor; Manipal College of Nursing, Manipal Academy of Higher Education Manipal MAHE, Karnataka, India

Abstract

Introduction: The increasing prevalence and high recurrence rate persuade to consider urolithiasis as thoughtful socio-medical issue and adequate knowledge is required to reduce the prevalence of urolithiasis.

Aim: To assess the knowledge on urolthiasis among patients attending OPDs in selected hospital of Udupi district Karnataka.

Materials and Method: A descriptive survey was conducted among 484 patients attending the out patients departments of a tertiary hospital in Udupi district Karnataka. The data were collected between 28th December 2017 and 16th March 2018 by using a structured knowledge questionnaire on urolithiasis. The inclusion criteria for subjects was age between 19-65 years (young adulthood and middle age) and able to read and write Kannada or English. Collected data were coded and analyzed by using descriptive statistics.

Results: Study revealed that out of 484 subjects, over half of the participants 358 (73.9%) were males and 298 (61.1%) were in the age group of 41 and 65 years. The mean knowledge score on urolithiasis was 11.6 out of maximum possible score of 30. Out of 484 participants 232 had knowledge score above mean and 252 had knowledge score below mean. The maximum obtained score was 6/7 in the area of introduction and 3/3 in signs and symptoms. In the area of management and prevention, participants obtained maximum score of 11/13. The maximum score obtained in the area of signs and symptoms.

Conclusion: Study showed that most of the participants were unaware about the risk factors, signs and symptoms, preventive measures. Majority of the subjects were below the knowledge mean score. Participants were aware about the signs and symptoms of urolithiasis where they obtained the maximum score. Hence, educating the general public is essential to improve the knowledge on urolithiasis and to decrease the burden.

Keywords: *Urolithiasis, kidney stone, renal calculi, urinary stones, knowledge.*

Introduction

Urolithiasis is one of the major diseases of the urinary tract and is a major source of morbidity. Stone formation is one of the painful urologic disorders that occur in approximately 12% of the global population and its re-occurrence rate in males is 70-81% and 47-60% in females[1]. Between 1% and 15% of people globally are affected by Kidney stones at some point in their life[2]. In 2015,22.1 million cases occurred, resulting in about 16,100 deaths (GBD 2015 disease and injury incidence and prevalence, 2016). They have become more common in the western world since 1970s[3].

The incidence of urolithiasis is universally increasing and contributes to an increasing economic and health care problem. The prevalence of urolithiasis is rising worldwide including both genders in different

Corresponding Author:
Shalini G. Nayak
Assistant Professor; Manipal College of Nursing, Manipal Academy of Higher Education Manipal Karnataka, India

age groups. Urolithiasis is one of the utmost common illnesses seen in Emergency Departments (ED) worldwide, with an uprising frequency in geriatric patients (>65 years). Given the high costs of emergency medical urolithiasis treatment, the basic to optimise management is obvious. Since the time of Hippocrates, urolithiasis has produced a challenge for clinicians and is still one of the most common conditions seen in emergency departments worldwide, with an estimated lifetime risk of 15–25%[4].

Abbagani et.al (2010) reported that the effect of geography on the incidence of stone formation maybedirect, through its effect on temperature, high temperatures increase perspiration, which may result in concentrated urine, which in turn promotes increased urinary crystallization[5]. In 2016, a retrospective study was conducted in a speciality hospital in Arakonam Taluk, Vellore district of Tamil Nadu. A total of 105 subjects were chosen for the study. All were suffering from mild to acute pain due to the formation of renal stones. Study conducted over a period of 22 months from 21st January 2014 to 15th October 2015. May to August months showed increased number of reported cases of renal stone among men. Among females, July- September months was the peak period and peer reviewed literature clearly states that region of residence contributes significantly to the formation of renal stones. Improper hydration and profuse sweating particularly during summer months increases the concentration of the urine resulting in precipitation of stones[6].

A descriptive cross sectional study was conducted in 2015 over a period of one week at Pedeniya, Srilanka. There were 290 consented patients presented to the OPD with urolithiasis selected for the study by simple random sampling technique. The study was based on a patient's demographic data and knowledge on risk factors and symptoms. The study results showed that the mean knowledge score was 9.03 out of 22 (41.06%, SD=2.14). None of the participants scored zero and none of the participants had the maximum score. Thus the knowledge on urolithiasis was poor[7].

Urolithiasis could be treated and the occurrence is prevented by proper education and management. So investigator intended to assess the knowledge of urolithiasis among patients attended OPDs at selected hospital in Udupi district Karnataka.

Materials and Method

This study was a hospital-based, cross-sectional survey, which was conducted among 484 patients who attended a tertiary care hospital in Karnataka, during December 2017 to March 2018. The inclusion criteria for the subject was age between 19 and 65 years (young adulthood and middle age) and able to read and write Kannada or English. The data were collected after obtaining approval from institutional ethics committee and administrative permission. The purpose of the study was explained with participant information sheet and informed consent obtained from participants prior to the data collection procedure. The questionnaire had questions in two major sections. Section 1 data collection tool consisted of demographic questions and section 2 was knowledge questionnaire. The knowledge questionnaire consisted of 30 multiple choice items from the areas of introduction, causes and risk factors, signs and symptoms and preventive measures of urolithisasis with one correct answer for each. Each correct answer carried one mark and zero for the wrong answer. All items had four alternative responses. The highest possible score was 30 and minimum score was zero. The knowledge scores were categorized as knowledge above mean score and knowledge below mean score for analysis and the mean score was 11.6.

Statistical Analysis: The obtained data were coded and analyzed by using SPSS version 16. A descriptive statistics were used to analyze the data. Frequency and percentage were used for demographic data and mean was used to analyze the knowledge scores.

Results

Section 1 - Description of demographic characteristics: The demographic characteristics of study population are given in Table 1. Study revealed that, out of 484 participants, 358 (73.9%) were males, 298 (61.1%) were in the age group of 41-65 years. Majority 358(73.9%) of the participants were belonging to Hindu religion. Few 231(47.7%) of the participants had previous information on urolithiasis. The source of information for 98 (20.2%) of the participants was from hospital.

Table 1. Demographic characteristics of study participants N=484

Sample characteristics	Frequency	Percent
Age in (Years)		
19-40	186	38.4
41-65	298	61.6
Gender		
Male	358	73.9
Female	126	26.1
Religion		
Christian	26	5.4
Hindu	358	73.9
Muslim	98	20.3
Others	2	.41
Previous information on urolithisasis		
Yes	231	47.7
No	253	52.3
Source of information		
Internet	32	13.8
Hospital	98	42.5
Others	62	26.8
TV	39	16.9

Section 2- Description of knowledge scores: The maximum possible score was 30 and minimum possible score was zero in the scale, whereas obtained mean knowledge score on urolithiasis was 11.6. Out of 484 participants, 232 had knowledge score above mean and 252 participants had below mean [Table 2].

Table 2. Knowledge mean scores of participants on urolithisasis N=484

Minimum		Maximum		Mean	Above mean	Below mean
Possible	Obtained	Possible	Obtained			
0	1	30	23	11.6	232	252

Table 3. Knowledge scores of participants on different areas of urolithiasis. N=484

Areas	Maximum Possible score	Minimum Possible score	Maximum Obtainedscore	Minimum Obtained score
Introduction	7	0	6	0
Causes and risk factors	7	0	6	0
Signs & symptoms	3	0	3	0
Management & prevention	13	0	11	1

The area wise description of knowledge on urolithiasis showed in the [Table 3] reveals that the maximum obtained score was 6/7 in the area of introduction and causes and risk factors, 3/3 in signs and symptoms. In the area of management and prevention participants obtained maximum of 11/13. The maximum score obtained in the area of signs and symptoms.

Discussion

Over half of the participants 358 (73.9%) were males and in the age group of 41-65 years 296(61.1%). Most 358(73.9%)of the patients were belongs to Hindu religion. Few 231(47.7%) of the participants had previous information on urolithisasis. The source of information for 98 (20.2%) of the subjects was from hospital. The mean knowledge score on urolithiasis was 11.6 and maximum possible score was 30 and minimum possible score was zero. Out of 484 samples 232 participants had knowledge score above mean and 252 participants had below mean.

A study conducted by Abdhulrida et.al in Saudi Arabia on assessment of patients knowledge about avoidance of recurrent urolithiasis shows that patients have poor knowledge about fluid and beverage intake in all items except in item (Drink plenty of fluid in hot weather situation and intense sweating and doing great work or while doing exercise.), and (Check the amount of urine output which must not be less than (2.5) liter/24 hours) and related to dietary intake in all items except in items (Reduce the intake of table salt. Increased sodium intake increases the risk of formation of gravel. By increasing the levels of calcium and reduce the level of citrate in the urine) and (Avoid eating fatty substances or cooked in fat)[8].

A study conducted by Sofia et.al. (2016) in National Institute of Siddha, Chennai on prevalence and risk factors of kidney stone also found the similar findings that nephrolithiasis is more common in men (64.56%) than in women (35.44%) it is more prevalent between the ages of 20 to 40 in both sexes (57.50%) [9].

A descriptive cross sectional study was conducted on 2015 over a period of one week at Pedeniya, Srilanka. There were 290 consented patients presented to the OPD with urolithiasis selected for the study by simple random sampling technique. The study was based on a patient's demographic data and knowledge on risk factors and symptoms. The study results showed that the mean an knowledge score was 9.03 out of 22 (41.06%, SD=2.14). None of the participants scored zero and none of the participants had the maximum score. Thus the knowledge on urolithiasis was poor [7]. A descriptive study which is conducted among inpatients of urology ward by Shambhavi et.al in Madurai also shows similar statistical findings of having poor knowledge among 80% of the subjects[10].

Conclusion

The present study shows that most of the participants are unaware about the risk factors, signs and symptoms and preventive measures. Majority of the subjects were below the knowledge mean score. So, there is need to improve the knowledge of risk factors for urolithiasis among general population by either collaborative approach by health education programs for them. Hence, educating the general public is essential to improve the knowledge on urolithiasis and to decrease the burden.

Efficacy of Menthol Infused Kinesiotaping in Forward Bending (Flexion) of Lumbar Spine in Mechanical Low Back Pain Patients: Interventional Study

Mohammad Zishan[1], Subrat Samal[2], Sohan Selkar[3], Swapnil Ramteke[4]

[1]PG Scholar, [2]Asso. Professor, Guide & HOD, Department of Musculoskeletal Sciences, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences (Deemed University), Sawangi (Meghe), Wardha, [3]Principal & HOD, Department of Musculoskeletal Sciences, Datta Meghe College of Physiotherapy, Wanadongri Nagpur, [4]Asso. Professor, Department of Sports Medicine, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences (Deemed University), Sawangi (Meghe), Wardha

ABSTRACT

Background: In all developed countries low back pain (LBP) is a considerable health problem which is the commonest problem treated in primary healthcare setting. It is defined as pain, muscle tension, or stiffness localized above the inferior gluteal folds and below the costal margin, with or without sciatica. The major symptoms of nonspecific LBP are disability and pain.

Aims & Objectives: To evaluate the effect of menthol infused kinesiotaping and conventional therapy in forward bending (flexion) of the lumbar spine in mechanical low back pain patients. Sample size:138 Subjects Group A -69 Subjects & Group B – 69 Subjects Study Design: Interventional Study setting: Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences (Deemed University), Sawangi (Meghe), Wardha Sample and Sampling Method: 138 Subjects were randomly selected and assigned in 2 groups, as Group 1(control group), Group 2 (Interventional group) in equal numbers. The Patients having mechanical low back pain, with the age group between 18-50 both genders & Willing to participate were included & the patients who were having PIVD with instability and radicular symptoms,Operated cases of spine, Lumbar spondylosis, lumbarcanal stenosis, spondylolisthesis, sensory deficits, Malignancy, Tuberculosis, Any infection or tumour around low back and pelvis were excluded.

Result: Mean pain on VAS in group A it was 3.52 ± 0.75 and in group B it was 5.53±0.76, Mean M-schobers test score in group A was 4.209±0.48 and in group B it was 3.653±0.25.

Conclusion: The inferences from the present study suggest that Menthol infused Kinesiotaping is more effective than Conventional therapy in management of Low back pain.

Keywords: *Menthol Infused Kinesiotaping, SWD, Low back Pain{LBP }, Melastatin, Chronic back pain (CBP).*

Introduction

In all developed countries low back pain (LBP) is a considerable health problem which is the commonest problem treated in primary healthcare setting. Therapeutic and diagnostic management of patients suffering from LBP has been characterized from so long by considerable variation between and within countries among practitioners, medical professionals and other healthcare professionals[1-2].

Chronic LBP is most common and 23% of worldwide population is affected with it,24-80% of population has recurrence rate at one year[3-4]. Prevalence of LBP is 80% in the general population, from which 50% of population recover spontaneously in 2 weeks and on another side 90% of population recover in 6 weeks. However, up to 60% of population have recurrence rate[5]. Chronic back pain (CBP) is a complex, heterogeneous medical condition that includes a wide variety of symptoms[6]. The occurrence rate of low back pain in India is high, where an individual is having significant LBP some or the other time in their life[7-8]. Only 20% of times exact anatomic cause of low back pain of mechanical origin can be identified, sometimes strenuous activity or specific trauma may be the cause of pain. Specific source of the LBP is not found 80% of the time. Fortunately most people recover in a short period of time with simple treatment. Mechanical LBP implies the source of pain is in the spine and/or its supporting structure. Mechanical low back pain refers to back pain that arises intrinsically from the intervertebral discs, spine, or surrounding soft tissues. Repetitive trauma/overuse are common causes ofchronic mechanical LBP, which is often secondary to workplace injury [9].

Method and Materials

Participants: One hundred and thirty eight (138) patients with mechanical low back pain, between the ages of 18-50 both genders, Willing to participate were included. Patient having PIVD with instability and radicular symptoms, Operated cases of spine, Lumbar spondylosis, lumbarcanal stenosis, spondylolisthesis, sensory deficits, Malignancy, Tuberculosis, Any infection or tumour around low back and pelvis were excluded from the study.

Procedure-

After obtaining Institutional Ethics Committee clearance. After satisfying inclusion and exclusion criteria the patients were allowed to participate in the study. The informed consent was obtained. Each subject was then tested for Lumbar range of motion using modified schobers test and Pain using VAS Scale in specific order:

Group A received the menthol infused kinesiotaping application with two 30 cm "I" strips while the subjects were in position of maximum forward bending of the spine. This application was performed simply by applying the tape to the skin with 0% tension. The participants were assessed for baseline parameters before intervention and data was recorded. The participants were again reassessed after 5 days of intervention and data was recorded. Pre and post test were carried out using Schobers test and Visual Analogue Scale[40].

Group B received Short wave diathermy for 10 mins, participant was kept in supine position the 2 electrodes of Short wave diathermy were placed on lumbosacral region, there was 2-4cm of distance between the two electrodes, the participant flexed the knees in order to flatten the back so that there should be complete contact between the electrodes and the surface of the body which is to be treated. The method used in this study is coplanar method, this technique produces greater heating in superficial muscle and tissues close to the electrodes. The treatment duration was for five days with single session per day. The participants were assessed for baseline parameters on 0^{th} day before applying SWD and data was recorded. The participants were again reassessed after 5th days of SWD treatment and data was recorded. Pre and post test were recorded[24]

Observation and Results

The data was coded and entered in Microsoft excel spreadsheet. Descriptive statistics included computations of means and standard deviation. Inferential statistics using student's paired t test and unpaired t test were used for comparison of all clinical indicators. Software used in the analysis was SPSS 22.0 version. The results were concluded to be statistically significant with $p < 0.005$, very significant $p < 0.001$ and highly significant $p < 0.0001$.

Table 1: Modified Schobers test Comparison in Group A Group B

	Mean	SD	t-test	P-Value	Inference
Group A	4.209	0.48	8.486	0.0001	Significant
Group B	3.653	0.25			

Table 2: Visual Analog Scale (VAS) Comparison in Group A and Group B

	Mean	SD	t-test	P-Value	Inference
Group A	3.52	0.75	15.456	0.0001	Significant
Group B	5.53	0.76			

Result

The table 1 shows that there were significant difference between group A and group B. Mean value

of group A and group B Modified Schober test score are 4.20 and 3.65 respectively. The t value were 8.48 and p value < 0.0001. These values suggests there is significant improvement in giving menthol infused kinesiotaping than conventional therapy similarly table 2 shows that there were significant difference between group A and group B. Mean value of group A and group B VAS score are 3.52 and 5.53 respectively. The t value were 15.456 and p value < 0.0001. These values suggests there is significant improvement in giving menthol infused kinesiotaping than conventional therapy.

Discussion

The current study aims to find out the efficacy of menthol infused kinesiotaping in forward bending (flexion) of lumbar spine in mechanical low back patients. In this study the total number of participants were 132, after 6 droupouts. Group A experimental and Group B control, each group consisting of 66 participants. The patient population was from the age group of 18-50 years. In the experimental Group A, the mean age was 34.68 and in the control Group B, it was 33.65. The justification for the selection criteria for the age group is supported by Kelle et al (2016), in their study the age group was of 18-65 years and Precee et al (2016) had the age group of 30-60 years.

The total number of participants in the study included both the genders, male and female. The male population in the A Group was 39 and the B Group was 29 respectively, whereas the female population was 27 and 37 respectively. Kelle et al had 109 participants, Precee et al (2016) took only 34 males, Alvarez Alvarez et al (2014) took 99 healthy subjects, Castro Sánchez et al (2017) took 60 subjects and Thiago et al (2014) took only 45 female.

Menthol is well known for its topical analgesic, antiseptic and cooling properties because it has a part in mediated activation of a melastatin of the transient receptor potential which is a super family of ion channels. It binds to TRPM 8 membrane channel causing menthol to induce cooling sensations to inflamed areas of skin/muscle via its anti nociceptive effects of capsaicinsensitive fibers which de-sensitize the peripheral neurons to signal from agitation and pain. Topical applications of menthol to a pain site have been shown to produce similar sensational effects to application of half a kilogram of crushed ice, along with similar blood flow reductions and breathing[24].

Short wave diathermy is a deep heating modality used for relief of pain. This significant effect is due to increased temperature in body tissues because of heat which causes increased arteriolar and capillary dilatation followed by increased blood flow to the area. Short wave diathermy (SWD) is a deep heating modality used in physical therapy treatment. Shortwave diathermy produces electric and magnetic fields alternating at high frequency due to which heat is produced in the body tissues when applied using a suitable method. Most of the physiological effects are produced because of heat generated in the tissues which has therapeutic benefits. The basic therapeutic mechanism being considered here is induction of relatively high frequency currents in the body tissues by alternating electric or magnetic field which produce the physiological effects and therapeutic benefits. The direct effect of heat causes relaxation of the muscle fibers which also helps in alteration in the physical characteristics of fibrous and muscular tissue such as in the tendons, muscles, joint capsules. The tissues yields more readily stretch, when heated [25].

Conclusion

In the present study, we found that both techniques Menthol infused kinesiotaping and conventional therapy are effective in increasing lumbar range of motion and reducing pain in mechanical low back pain patients. Results of this study suggests that there was improvement throughout the session. The pre and post score of Visual Analoq Scale (VAS) and Lumbar flexion showed improvement in both the groups i.e Group A and Group B but more significant improvement was observed in Group A receiving Menthol infused kinesiotaping. The present study rejects the null hypothesis and accepts the alternate hypothesis i.e Menthol infused Kinesiotaping is more effective than Conventional therapy in management of Low back pain.

Ethical Clearance: It has been obtained by Datta Meghe Ethical Committee, Dmims, Sawangi Meghe Wardha.

Comparative Evaluation of Antimicrobial Efficacy of Chlorhexidine and Aloe Vera against Enterococcus Feacalis: An in Vitro Study

Nadhirah Faiz[1], Mebin George Mathew[2]

[1]Undergraduate Student, [2]Senior Lecturer, Department of Pedodontics and Preventive Dentistry, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences, 162, Poonamallee High Rd, Velappanchavadi, Chennai, Tamil Nadu

Abstract

Aim: To compare and evaluate the antimicrobial efficacy of Chlorhexidine (CHX) and Aloe Vera extracts as a root canal irrigant against Enterococcus faecalis.

Materials and Method: The bacterial E. faecalis (ATCC) culture was grown overnight in brain heart infusion (BHI) broth and inoculated in Mueller-Hinton agar plates. Antibacterial inhibition was assessed using agar well diffusion method. All five study irrigants were added to respective wells in agar plates and incubated at 37°C for 24 h. Bacterial inhibition zone around each well was recorded. Results were tabulated and statistically analyzed using Statistical Package for the Social Sciences software for Windows, version 19.0. (IBM Corp., Armonk, NY.

Results: Highest inhibitory zone against E. faecalis was seen in Highest inhibitory zone against E. faecalis was seen with 2% CHX followed by 5% Aloe Vera while 100% Aloe vera showed least inhibition.

Conclusion: Aloe vera showed inhibitory action against E. faecalis but was not as effective as 2% CHX.

Keywords: *Antimicrobial, root canal irrigants, herbal, aloe vera, chlorhexidine*

Introduction

The complete elimination of microorganisms from the root canal and the three-dimensional obturation of the canal space results in a successful root canal treatment.[1] Pulpal and periradicularpathosis occurs due to invasion of he root canal by microrganisms. Enterococcus faecalis (E. faecalis) is the most commonly isolated microrganim from failed root canals. It is an anaerobic gram-positive bacterium which has the ability to invade dentinal tubules and its existence does not depend on the presence of other bacteria. It is highly resistant to intracanalmedicamnets which lead to its virulence allowing it to have obligatory role in persistent failure of endodontic therapy. [2] Cleaning and shaping of canals alone is not sufficient for the success of an endodontic treatment. It should be always assisted with chemical debridement, which consists of using various irrigating solutions.[3] Sodium hypochlorite is the most commonly used as root canal irrigant due to its various advantageous properties. Disadvantages include the allergy, sodium hypochlorite accident, metallic taste and toxicity.[4]

Chlorhexidine (CHX) is a broad spectrum antimicrobial which has been used as irrigant due its sustained broad spectrum action and low toxicity. Chemically CHX is a synthetic cationic bis-guanide that owes its effectiveness due its positive charge which interacts with the negative charge of the phoshate group on the microbial wall, resulting in alteration of osmotic equilibrium of the cell.[5]

The use of herbal products has been as irrigants is gaining acceptance due its safety, efficiency and acceptability. One such herb that has been investigated is Aloe Vera (Aloe barbadensis Miller), owing to its antibacterial effect against E. faecalis.[6] There is a deficiency of adequate studies regarding the use

of aloe vera as a root canal irrigant. Hence this study was undertaken to evaluate the antimicrobial efficacy of different concnentrations of Aloe Vera against Chlorhexidine using agar diffusion test.

Materials and Method

Ethical Clearance was obtained from the Institutional Review Board before the start of the study.

Source of Data: The bacterial stock culture of Enterococcus faecalis strain (ATCC 29212) was obtained from JP Laboratories, Davangere, India and the extracts Aloe vera were prepared.

Aloe Vera extract preparation: Leaves was taken from fresh Aloe Vera plants and its pulp was extracted by hand. Aloe Vera plant pulp was then mixed with Chloro form water i.e. 2.5 ml of Chloroform in 1000 ml of purified water (Indian Pharmacopoeia) and mixture was filtered using a double filter paper and the supernatant was then centrifuged at 8,000 rpm for 40 min to obtain the extract.

The concentrated solutions thus prepared from all the above ingredients was weighed and using distilled water, serial dilutions of 5 ml/95 ml, 25 ml/75ml,50 ml/50 ml and 100 ml (volume/volume) was made in order to obtain 5, 25, 50 and 100% concentrations,respectively, for the evaluation of antimicrobial activity against E. faecalis. The antimicrobial testing was done on the same day of extracts prepared.

Agar diffusion test: The bacterial stock culture of Enterococcus faecalis (ATCC 29212) was obtained from JP Laboratories, Davangere India. The standards train of Enterococcus faecalis (ATCC29212) was grown on Brain Heart Infusion (BHI) broth overnight and turbidity was adjusted to 0.5 Mc Farl and scale to obtain a cell density of 1.5X108 bacterial/mlandinoculated in Mueller Hinton Agar plates. Inoculation was performed by using sterile swab brushed across the media. Four round wells measuring about 4 mm deepand 8 mm in diameter was punched using a sterile stainless steel template and they are numbered as 1, 2, 3 and 4 consecutively for the different concentrations used for the each test group to be evaluated. As control 0.2% chlorhexidine gluconate solution was taken for the evaluation.

Group A was allocated for Chlorhexidine and Group B was Aloe Vera extract consisting of 15 inoculation agar plates in each group. After making serial dilutions of the extract and four round wells in each agar plate, 50uL of specific concentration of each extract was dispensed into each well using a sterile micro pipette. This was done in triplicate fore very concentration so as to overcome any inadvertent technical errors. This was done for each group in the same way. All agar plates was then incubated at 37°C for 24 hours, according to Clinical Laboratory Standard Institute guidelines. Following 24 hours of incubation at 37°C, zones of inhibition (that is areas where no growth of bacteria is present)was examined around each well. They appeared as a clear, circular halo surrounding the wells. Diameters of the bacterial growth inhibition zones or halos was measured using a Hi Antibiotic Zonescale in millimeters and this represented the inhibition value.

Results

The antibacterial activity was evaluated using Agar well Diffusion test by measuring the zone of inhibition around each of the four wells.. The results were subjected to statistical analysis by applying Analysis of Variance and Post Hoc Tukey HSD tests for multiple comparisons. On applying one way Analysis of Variance, a statistically significant difference was seen between the zone of inhibitions of different samples within groups and between groups i.e. $P < 0.001$.

The meanzone of inhibition for positive control that is Group A (0.2% Chlorhexidine) was 18.36 mm, with which all other values was compared.

Comparison between Group A (0.2% Chlorhexidine) and Group B (Aloe vera) with different concentrations of 5%, 25%, 50% and 100%was 0.52 mm, 0.98 mm, 3.02 mm, 5.43 mm respectively (Table 2) which was less than Group A (0.2% Chlorhexidine) - 18.36 mm and the difference was statistically significant because of P value < 0.001 which is tabulated in Table 1 .

It is was seen Aloe Vera did not have mean zone of inhibition more than Group A (0.2% Chlorhexidine) it showed minimum effectiveness at 100% concentration.

Discussion

The prime objective of root canal treatment is to eradicate the microorganisms from the root canal and to intercept their recontamination in the post treatment period. Hence irrigant solutions must accompany the action of the mechanical instruments to ensure the complete cleanliness of the canal.[7]

The success of endodontic treatment can be seen in the quality of the obturation. Root canals that are unsatisfactorily obturated provide greater space and nutrition than well-obturated canals and the available space may create a facultative anaerobic environment. In contrast, well-obturated canals maintain an obligate anaerobic environment that does not favour the survival and growth of E. faecalis. Inadequate cleaning and shaping may also have left infected debris behind. Microorganisms such as E. faecalis can survive within the small canals of apical ramifications or in the space between the root filling and canal wall. In fact, E. faecalis strains can survive for at least 6–12 months in an environment where nutrients are scant and when commensality with other bacteria is reduced. E. faecalis is also extremely resistant to chemicals, including calcium hydroxide.[8] E. faecalis has an inheret ability to adhere to dentin and invade dentinal tubules and to forms communities organized in biofilms, which may contribute to bacterial resistance and persistence after intracanal antimicrobial procedures. It also has the capacity to survive in an environment in which there are available nutrients and in which commensality with other bacteria is minimal.[9]

Using root canal irrigant solutions has proved to be essential in endodontic treatment as they aid in disinfecting and lubricating the root canal, flushing out debris from the canal system and dissolving organic and inorganic tissues. To effectively clean and disinfect the root canal system, an irrigant should ideally: (a) have a broad antimicrobial spectrum and high efficacy, (b) be able to digest proteins and necrotic tissue, (c) prevent the formation of a smear layer during instrumentation or dissolve the latter once it has formed, (d) present low surface tension to reach areas inaccessible to the tools (dentin tubules), (e) offer long-term antibacterial effect, (f) keep dentinal debris in suspension, (g) provide a lubricating action for root canal instruments, (h) be non-antigenic, non-toxic and non-carcinogenic. In addition, it should have no adverse effects on dentin or the sealing ability of filling materials. Furthermore, it should be relatively inexpensive, convenient to apply and cause no tooth discoloration.[9,10]

Chlorhexidine is used extensively as a root canal irrigant because of its substantivity and antimicrobial effects against Gram-positive and Gram-negative organisms. The property of substantivity allows prolonged time of action for CHX. CHX is less toxic compared to sodium hypochlorite and does not have foul taste. · It has excellent antibacterial, antifungal and acts on the biofilm.[10] It has been proposed that CHX should

be used in open apex cases. However disadvantage is inferior tissue dissolving properties. If Chlorhexidine is extruded through the apex, it does not induce pain to the patients. However, the structure of the Chlorhexidine molecules poses a systemic risk because it is likely to decompose into reactive byproducts, such as para-chloroaniline.[9]

CHX is a synthetic cationic bis-guanide consists of two symmetric 4-cholorophenyl rings and two biguanide groups connected by a central hex am ethylene chain. CHX is a positively charged hydrophobic and lipophilic molecule that interacts with phospholipids and lipopolysaccharides on the cell membrane of bacteria and then enters the cell through some type of active or passive transport mechanism . Its efficacy is due to the interaction of positive charge of the molecule and negatively charged phosphate groups on the microbial cell walls, thereby altering the cells' osmotic equilibrium. This increases the permeability of the cell wall, which allows the CHX molecule penetrate into the bacteria. CHX is a base and is stable as a salt. The most common oral preparation, chlorhexidine gluconate, is water-soluble and at physiologic pH, readily dissociates and releases the positively charged CHX component. At low concentration (0.2%), low molecular weight substances specifically potassium and phosphorous will leak out. On the other hand, at higher concentration (2%), CHX is bactericidal; precipitation of cytoplasmic contents occurs resulting in cell death.[10,11]

Aloe vera is a naturally occurring herbal medicament having antibacterial properties, anti-inflammatory, antibacterial, antifungal and antiviral properties. The presence of anthrax quinine allows it to inhibits E.faecalis and Streptococcus pyogenes.[12] Karkare et al[13] concluded that Aloe Verashowed the highest zone of inhibition against E. faecalis which is in contrast to our results. Our results are similar to Babajiet al[14] and Jose et al[15], who have shown that CHX has superior antimicrobial efficacy when compared to Aloe Vera. The probable reason for the decreased antimicrobial efficacy of Aloe vera could be due to change in weather where the plant was grown and where it was prepared.[16] Second, tooth structures themselves might lessen the antibacterial effect of Aloe vera solution. Lawrence et al. stated that microbial toxicity of Aloe Vera is related to the site and number of hydroxyl groups in the phenol groups.[17] Hydroxyl groups are responsible for alkalinity and antibacterial action of calcium hydroxide but its effect is relatively neutralized by dentin buffering action. Therefore, the antibacterial activity of Aloe Vera was suppressed by this mechanism. Third, the gel-like consistency of Aloe Vera could cause limited flow of the substance through the irregularities of the root canal system

Limitations of the study are that it was an invitro study with a limited sample size and biofilm protection produced by endodontic microflora could not be employed.

Conclusion

Aloe vera showed inhibitory zone against E fecalis. However, it was less than 2% CHX. Hence, these can be used as root canal irrigating solutions but furtherin vivo research is required to test these herbal medicines and to modify its content for acceptability by patients.

Abstract

Objectives: The objectives of the study were to assess the knowledge regarding refractive errors among high school students, to find the association between knowledge score and selected demographic variables and to prepare informational booklet.

Method: A descriptive survey was conducted among 100 students from selected High Schools at Mangaluru on August 2019. Non probability convenient sampling technique was used in the study to select the sample. The structured questionnaire was used as the tool for finding the knowledge of the students regarding refractive errors.

Result: The result showed that the mean percentage of knowledge score was 68.2%.The study also shows that there is significant association between knowledge score and selected demographic variables such as standared of study and type of electronic media. Also no association between knowledge score and selected demographic variables such as age in years, gender, type of family, place of residence, hours spending in front of electronic media and awareness regarding refractive errors.

Conclusion: The findings of the study revealed that the students had average level of knowledge on refractive errors and there was significant association between knowledge and some selected demographic variables.

Introduction

Eye is like a camera. The external object is seen like the camera, takes the picture of any object. Light enters the eye through a small hole called pupil and is focused on the retina which is like a camera film. Eye also has a focusing lens which focuses images from different distances of the retina. When the eyes are exposed to excessive strain, develops abnormality in normal functioning of the eye. It is common among children as well as adults. The highest risk of eye disorder occurs due to the excessive strain in the eye is refractive errors. and it is commonly found in students. Refractive error is a very common eye disorder it occurs when the eye cannot clearly focus the images from the outside world. The result of refractive errors is blurred vision which is sometimes so severe, that causes visual impairement.[1]

The most common types of the refractive error are near sightedness (myopia), far sightedness (hyperopia), astigmatism and presbyopia. Myopia results in far objects being blurry, hyperopia results in close objects being blurry, astigmatism causes objects to appear stretched out or blurry and presbyopia results in poor ability to focus on close objects.[2]

Today refractive error is a very common eye disorder in all over world. Especially these problems commonly

seen in adolescents. According to WHO(world health organization) it is estimated that globally 153 million people over 5 years of age visually impaired as a result of uncorrected refractive errors of whom 8 million peoples are blind.[3]

The overall prevalence of refractive errors is 44.1%.Estimates of people worldwide with refractive error range from 800 million to 2.3 million and5-15% of all children are considered to have refractive errors. The highest prevalence of refractive error is in China. The prevalence of refractive error has been reported as high as 70-90% in some Asian countries, 30-40% in Europe and the United states and 10-20% in Africa. In India about 40% of the population in the age group of 6-10 years is having eye disorders. In Karnataka, the prevalence of refractive errors among school children is about 9-10%.Myopia accounts the highest, hyperopia 5.3% and astigmatism 1.18%.[4]

Now a days the prevalence of refractive errors has been increased. The rise of refractive errors may be due to the excessive use of electronic media. The effort to decrease the refractive errors is very critical because adolescence are the highest population who using electronic media[5]. According to the World Health Organization (WHO), over 340 million children and adolescence aged 10-15 years were having spectacles[6]. Limiting the duration of use of electronic media will help adolescence to maintain eye health and prevent vision problems.

Materials and Method:

The study was conducted in a school at Mangaluru and the school were selected based on the feasibility of conducting the study and the availability of samples. The non probability convenient sampling technique was used for the selection of samples. The study samples were consisting of 100 high school students. The structured knowledge questionnaire was used to assess the knowledge regarding refractive errors. The data were analyzed using descriptive statistics.

Result

Section 1: Demographic data: The section deals with characteristics of 100 students in terms of frequency and percentage. The data is presented in Table 1.

Table 1 shows that, frequency and percentage distribution of subjects on the basis of their demographic data. In this, 56% of the students were in the age group of 13 years, 58% of them were males, 76% of the students belongs to nuclear family, 54% of the students studying at 8th standared, 78% place of residence is rural area,75% have television as type of electronic media at home,70% spent 1 hour in front of media and 63% has awareness regarding refractive errors.

Table 1. Frequency and percentage distribution of subjects on the basis of their demographic data. N=100

Sl.No.	Variables	Frequency (f)	Percentage (%)
1.	**Age in Years**		
	a. 13 years	**56**	56
	b. 14 years	37	37
	c. 15 years	7	7
2.	**Gender**		
	a. Male	**58**	58
	b. Female	42	42
3.	**Type of family**		
	a. Nuclear	**76**	76
	b. Joint	24	24
	c. Extended	00	00
4.	**Standard of study**		
	a. 8th standard	**54**	54
	b. 9th standard	46	46
	c. 10thstandard	00	00
5.	**Place of residence**		
	a. Rural	**78**	78
	b. Urban	22	22
6.	**Type of electronic media at home**		
	a. Television	**75**	75
	b. Computer	25	25
	c. Mobile phone	00	00
	d. Laptop	00	00
7.	**Hours spent in front of media**		
	a. 1 hour	**70**	70
	b. 2 hours	22	22
	c. 3 hours	5	5
	d. >3 hours	3	3
8.	**Awareness regarding refractive error**		
	a. Yes	**63**	63
	b. No	37	37

Section 2: Distribution of subjects according to their knowledge score.

Table 2. Frequency and percentage distribution of subjects according to their knowledge score. N=100

Level of Knowledge	Frequency (f)	Percentage (%)
Poor	0	0
Average	44	44
Good	56	56

Table 2 illustrates that the majority of the students (56%) had good knowledge,44% had average knowledge and 0% had poor knowledge about refractive errors.

Section 3: Association between level of knowledge and selected demographic variables.

In order to find out the association between knowledge and selected demographic variables, the following hypothesis was stated.

H_1: There will be significant association between knowledge and selected demographic variables.

Table 3. Association between knowledge and selected demographic variables.

Sl.No.	Variables	Rating			Df	Chi square (x^2)	Inference
		Good	Average	Poor			
1	**Age in years**						
	13	35	21	0	2	4.080	NS
	14	16	21	0			
	15	5					
2.	**Gender**		2	0	1	2.064	NS
	Male	36	22	0			
	Female	20	22	0			
3.	**Type of family**						
	Nuclear	40	36	0	1	1.458	NS
	Joint	16	8	0			
4.	**Standard of study**						
	8th standard	30	24	0	1	0.009	S
	9th standard	26	20	0			
5.	**Place of residence**						
	Rural	47	31	0	1	2.607	NS
	Urban	9	13	0			
6.	**Type of electronic media**						
	Television	42	33	0	1	0.000	S
	Mobile phone	14	11	0			
7.	**Hours spent in front of electronic media**						
	1 hour	43	27	0	3	4.599	NS
	2 hour	10	12	0			
	3 hour	1	4	0			
	>3 hour	2	1	0			
8.	**Awareness regarding refractive errors**						
	Yes	50	13	0	1	37.725	NS
	No	5	31	0			

NS = Not Significant; S = Significant

The data presented in the table 6 shows that, there was association between 2 demographic variables such as standard of study, type of electronic media at home and knowledge score of students, since the calculated value was greater than the table value at 0.05 level of significance, Hence H1 is accepted for these variable. and there was no association between age in years, gender, type of family, place of residence, hours spending in front of electronic media and awareness regarding refractive errors and knowledge score of students, since the calculated value was lesser than the table value at 0.05 level of significance. Hence H_1 is rejected; H_0 null hypothesis is accepted for these variables.

Discussion

Part – 1: Demographic characteristics of sample: The findings of the study revealed that among 100 students majority (56%) of students were belongs to the age group of 13 years, around 58% were males, majority (76%) were belongs to nuclear family. In that around (54%) of students studying in 8th standard. The place of residence was rural area for 78% of the samples. Majority 75% were using Television and 70% of they were using electronic media for 1 hour. Majority 63% of students were having awareness about refractive errors.

Part–2: The knowledge of students regarding refractive error.

Section A: assessment of the level of existing knowledge: The findings of the present study reveal that the mean percentage of the student's knowledge regarding refractive errors is 68.2%with mean and standard deviation is 20.46,±4.217 respectively. Most 56% of the samples had good knowledge and 44%had average knowledge regarding the refractive errors.

Section B: Area wise analysis of the existing knowledge: The overall knowledge of students regarding refractive errors is 68.2% with mean 20.46 and standard deviation±4.217. Area wise analysis revealed that the samples scored highest in the area of "Anatomy, physiology, meaning and incidence "with mean percentage of 76.6%, mean and SD is 6.90,±1.636 respectively; In the area of risk factors, causes, types, signs and symptoms the mean percentage was 59.7%and in the area of diagnostic evaluation, treatment, complications prevention the mean percentage was 69.9%.

Part 3: Association of knowledge score of students with selected demographic variables: The findings of the study revealed that there is significant association between the knowledge score and demographic variables such as standard of study, type of electronic media at home, since the calculated value was greater than the table value at 0.05 level of significance, Hence H1 is accepted for these variable. and there is no significant association between the knowledge score and demographic variable like age, gender, type of family, place of residence, hours spent in front of electronic media and awareness regarding refractive errors, since the calculated value was lesser than the table value at 0.05 level of significance. Hence H_1 is rejected; H_0 null hypothesis is accepted for these variables.

Conclusion

The study result showed that the mean percentage of the student's knowledge regarding refractive errors is 68.2% with mean 20.46 and SD±4.217. Most 56% of the samples had good knowledge and 44% had average knowledge regarding refractive errors.

Acknowledgement: The authors are thankful to the principals who permitted us to conduct our study in their schools. We are also thankful to the students for extending the full cooperation to the study.

Ethical Clearance: Yenepoya Ethics committee-1 approved our study protocol number2018/056 titled "A study to assess the knowledge regarding refractive errors among students of selected high schools in Mangaluru with a view to prepare information booklet" on 23/06/2018 under the chairmanship of Dr.Vikramshetty.

Effect of Foot Reflexology on Lactation

Nikita Machhi[1], Anjali Tiwari[2]

[1]M.Sc. Nursing, [2]Assistant Professor and HOD, Dept. of Obstetrics & Gynaecological Nursing, Manikaka Topawala Institute of Nursing, Charotar University of Science and Technology, Gujarat, India

Abstract

Background of the study: Soon after delivery till 6 weeks lasts the postnatal period. Mothers undergoes with many physiological and emotional changes during this period and learn that how to overcome with these problems. From the mammary glands, mother produces breast milk during postnatal period called as lactation. Breast feeding is important to provide complete nutrition to baby. Most of the women are able to produce enough breast milk to support the growth of their child, but some women face difficulty to produce breast milk because of many factors. Foot reflexology has been considered as a complementary therapy by many western countries from 1930 onwards. It is a non pharmacological method which includes the application of firm continuous pressure at specific points of the body which in turn help release endorphins, promote lymphatic flow in the body and even promote blood circulation. It also has significant effect on hypothalamus for hormone production.

Methodology: A Quasi- experimental study was done on 90 participants (45 participants in each experimental and control group)who were recruited from selected hospitals of central Gujarat. Tools of data collection included performa of demographic and maternal variables and Infant breastfeeding assessment tool. The intervention was given to experimental group participants by application of foot reflexology 2 times per day for 3 consecutive days. Investigator assessed the lactation after 30 minutes of the last intervention.

Result: Wilcoxon signed rank test was used to determine the effect of foot reflexology on lactation among postnatal women of experimental group and control group. There was statistically significant difference found on all the parameters of Infant breastfeeding assessment tool among experimental group at p value <0.001.

Conclusion: The study concluded that foot reflexology were effective in improving lactation among postnatal women. Hence, it can be used as a non-pharmacological method of improve lactation.

Keywords: *Foot reflexology, lactation, postnatal women.*

Introduction

The postpartum period begins from delivery of fetus till 6 weeks. Mothers undergoes many physiological & emotional changes during postnatal period and learn how to overcome with the minor health ailments that arise during this period.[1] According to WHO, there exists Scientific evidence that support the importance of breastfeeding practices for reducing child mortality and morbidity, malnutrition and noncommunicable diseases in adult life. The world breastfeeding week 1–7 August focused on "Empower Parents, Enable Breastfeeding" in the year 2019. According to UNICEF (2018), only 41.6% of babies are breastfed within an hour of being born. The India New-born Action Plan (INAP) developed by Ministry of Health & Family Welfare in 2014, is also targeting a 75% rate of initiation of breastfeeding within

Corresponding Author:

M.Sc. Nursing, Manikaka Topawala Institute of Nursing Charusat, Gujarat
e-mail: nick1361995@gmail.com

an hour of birth by 2017 and a 90% by 2025. [2]All these statistics suggests the importance of lactation in the lives of the postnatal mother and the newborn.

Lactation is very important as it provides the pivotal and ideal nutrition to the newborn in the form of breastmilk. Prolactin stimulates the production of breast milk during lactation whereas oxytocin is responsible for stimulation of milk ejection. But there exists many reasons which can affect the entire process of lactation leading to its failure.[3]

For the treatment of inadequate breastfeeding there are mainly two method: Pharmacological and non-pharmacological. Non-pharmacological method take longer time to cure problem but it provide complete relief from the problem with minimal or no side effects. It is a non pharmacological method which includes the application of firm continuous pressure at specific points of the body which in turn help release endorphins, promote lymphatic flow in the body and even promote blood circulation.[4] It also has significant effect on hypothalamus for hormone production.There are few researches that show the efficacy of foot reflexology for early initiation of breast feeding but such studies in India and Gujarat are not much in number. Hence the researcher felt the need take up this research.

Material and Method

A Quasi- experimental study was undertaken at selected hospitals of Central Gujarat. Ethical clearance and formal permissions were obtained prior to conduction of the study. 90 postnatal mothers were conveniently recruited and then randomly allocated to experimental and control group (45 each). Researcher developed baseline data performa and Infant breastfeeding assessment tool was used to collect data. Pre- intervention assessment was done for both the groups. For experimental group along with routine care, the researcher administered foot reflexology by application of pressure with the thumb and index finger using acupressure thumb on the big toe of the each foot for 10 minutes each with a rest interval of 5 minutes in between each feet pressure session. This was done twice a day for 3 consecutive days. Whereas for control group only routine care was provided. Post intervention assessment was done for both the groups after third day.

Result

Wilcoxon signed rank test was used to determine the effect of foot reflexology on lactation.

Table 1: Comparison of Infant breastfeeding assessment tool in experimental group and control group. N=90

Infant Breastfeeding Assessment Tool					
Tool	**Group**	**Day 1 Median**	**Day 3 Median**	**Wilcoxon test**	**P value**
In order to get baby to feed	Experimental	1	3	6.018	<0.001
	Control	1	1	2	0.056
Rooting	Experimental	1	3	5.899	<0.001
	Control	1	1	0.816	0.414
Placing baby on breast to latch and suck	Experimental	1	3	5.858	<0.001
	Control	2	2	1.55	0.257
Sucking pattern	Experimental	1	3	5.929	<0.001
	Control	1	1	1.155	0.248

The data presented in table indicates that there was statistically significant difference found on all the parameters of Infant breastfeeding assessment tool among experimental group with p value <0.001. Hence, the research hypothesis stands accepted which state that there is statistically significant effect of foot reflexology among postnatal women at 0.05 level of significance.

Fisher's chi square test was used to find the association between pre- intervention lactation of

postnatal women of both experimental and control group with their socio demographic and maternal variables. There was statistically significant association found between rooting with Gravida (df= 6 and P value= 0.048) and Sucking pattern with breastfeeding after delivery (df= 6 and P value=0.021) of experimental group. Whereas Sucking pattern with breastfeeding after delivery (df= 4 and P value=0.047) and Sucking pattern with frequency of breastfeeding (df=4 and p value= 0.04) of control group too showed association. Remaining variables were statistically independent as they did not have any association.

Conclusion

The study concluded that foot reflexology are effective on lactation. Hence, foot reflexology can be used as a non-pharmacological method to improve lactation.

Ceftazidime-Resistant Burkholderia Cepacia: An Unusual Case in a Paediatric Patient

Nirmal Kumar Mahakud[1], Surya Narayan Mishra[1], Sibabrata Pattnaik[1], Mukesh Jain[2], Rishab Pugalia[3]

[1]Associate Professor, [2]Assistant Professor, [3]Post Graduate Student, Dept. of Paediatrics, Kalinga Institute of Medical Sciences, Bhubaneswar, Odisha

Abstract

Intensive care unit (ICU) sepsis in paediatric patients is a common clinical entity in tertiary care settings. Emergence of pathogens showing multidrug resistance pattern and causing ICU sepsis is widespread and poses a severe threat to physicians in treating them. At times, physicians find a pathogen they have never encountered before. Burkholderiacepacia infection in small children admitted in paediatric Intensive care unit (PICU) is rare. This infection is common in immunocompromised patients and underlying other debilitating disorders. We report a case of a 3-year and 06 month-old female child diagnosed with ceftazidime-resistant Burkholderiacepacia in an PICU setting.

Keywords: *Burkholderia, ceftazidime, drug resistant, sepsis.*

Introduction

Burkholdriacepacia has emerged as an important cause of hospital-acquired infections. The bacterium is known formerly as *Pseudomonas cepacia*, a gram negative aerobic, glucose, non-fermenting, motile bacillus. Immunocompromised and hospitalized patients are especially prone to this type of infection, leading to severe bacteremia that may also resultin death[1]. We present a case of a 3-year and 06 month-old female child who was found to have signs of respiratory tract infection followed by Burkholderia sepsis in a healthcare setting. We faced lots of difficulties in treating the patient because the pathogen was found to have resistance to ceftazidime which is usually considered as the mainstay of treatment. Informed consent was obtained from the patient's parents to report this case.

Mob: 8093401845, 9535434723
e-mail: surya.mishra@kims.ac.in

Case Presentation: A 3-year and 06 month-old female child was brought to the paediatrics emergency with high grade fever with convulsions and vomiting which was non-projectile and non-bilious. She was apparently alright five days back when she developed fever which was of sudden onset, high grade and not associated with chill and rigor. The fever was subsiding with medication and recurring again. In this current episode the fever was very high grade with convulsion and watery diarrhoea. She had developed swelling of both lower limbs and abdominal distension for 3 days which was gradual in onset.

On examination, the patient was drowsy with no signs of meningeal irritation. She was looking sick with presence of pallor and koilonychia. She had a respiratory rate of 25/min, a blood pressure of 72/54 mm Hg and a pulse of 92/min, which was regular with good volume and no radio-radial or radio-femoral delay. Systemic examination was unremarkable, including the cardiovascular, gastrointestinal and central nervous systems. Respiratory system examination was positive for left lower lobe crepitation.

Her laboratory investigations revealed a total leukocyte count (TLC) of 26,000 cells per microliter, hemoglobin -10 g/dL, platelets – 2,24,000 per microliter,

creatinine – 0.5 mg/dL, blood urea - 86 mg/dL, serum albumin – 1.4 gm/dL, total bilirubin - 0.2 mg/dL, serum total protein -3.4 gm/dL, serum albumin – 1.4 g/dL, serum globulin 2.0gm/dL, international normalized ratio (INR) - 1.6, activated partial thromboplastin time (a PTT) of 56 seconds and a prothrombin time (PT) of 19 seconds. The viral markers like HIV, HCV and HBsAg were all negative. To rule out other causes of fever like Dengue and Scrub typhus which is also seen in Odisha; samples were sent for testing by ELISA and it came to be negative.

She was put on piperacillin/tazobactam empirically. Her respiratory distress worsened over the next day; a decision was made to put her on mechanical ventilation because of acute respiratory distress syndrome (ARDS). Chest X-ray showed bilateral infiltration. Before starting the antibiotic, clinical samples like blood, urine, endotracheal tube aspirate were sent for culture sensitivity using automated BacT Alert and Vitek-2 systems. Over the coming days, her leukocytosis worsened with a TLC up to 46,000 per microliter and her condition became critical with deranged renal function tests, liver functions tests, prothrombin time and international normalized ratio (INR). Her antibiotic was changed to meropenem. The blood culture and endotracheal tube aspirate revealed the presence of ceftazidime resistant *Burkholderiacepacia* showing resistance to other antibiotics like Colistin, Imipenem, Piperacillin/Tazobactam, Ticarcillin/Clavulinic acid. As the isolated organism was sensitive to Meropenem, Cefepime, Cefoperazone/sulbactam, Ciprofloxacin, Levofloxacin and Trimethoprim/Sulfamethoxazole; the antibiotics were also changed to Meropenem. On the ninth day, the patient was weaned off from the ventilator, as the signs of sepsis were decreasing and she started with oral feeding. The antibiotic was continued and she was discharged from the hospital on the 16th day. She was advised to take oral Trimethoprim/Sulfamethoxazole with a regular follow-up.

Discussion

Burkholderiacepacia is an important nosocomial pathogen in hospitalised patients, particularly those with prior broad-spectrum antibacterial therapy. It causes infections that include bacteraemia, urinary tract infection, septic arthritis, peritonitis and respiratory tract infection[2].The respiratory tract is the most common route for an infection by *Burkholderiacepacia*, followed by intravascular catheters[3]. Our patient appeared to have an infection in the lungs accompanied by bacteremia. *Burkholderiacepacia* can also be spread directly or indirectly from saliva or fomites of patients with cystic fibrosis[4]. Risk of spread is higher by direct exchange of respiratory secretions due to kissing or intimate social contact[5].The ability for *Burkholderia* species to thrive in the diverse range of environments is testament to the fact that they can be considered as one of the most versatile groups of gram-negative bacteria.

In the present case, the initial symptoms of headache, convulsions and bilateral pitting edema with abdominal distension can be explained by the septicaemia. She was put on broad-spectrum antibiotics and assisted ventilation. With the help of culture and sensitivity testing, we were able to identify ceftazidime-resistant *Burkholderiacepacia*, but we were unable to identify the source of infection. We thought of bacteremia due to hospital acquired infection as the child was taking medication for the fever from several physicians on several occasions. The drug of choice for the empirical treatment of Burkholderiacepaciabacteremia, in this case, was meropenem as it also covered the other suspected causes of sepsis.

A similar case of an outbreak of Burkholderiacepaciabacteremia in a pediatric intensive care unit has been reported by Antony, et al. from South India[6]. The source of this outbreak was found to be contaminated distilled water.Most of the infections caused by *Burkholderiacepacia* are found in immunocompromised patients with opportunistic infections and especially those with HIV infection and cystic fibrosis[7].

Ribonucleic acid (RNA) sequencing revealed that the overexpression of resistancenodulation-division (RND)-3 pump activity was attributed to mutations in the efflux pump regulator gene. This can account for the mechanism of ceftazidime resistance in this pathogen. In a recent study, it has been found that avibactam can restore the activity of ceftazidime in ceftazidime-resistant Burkholderia species[8].

The success of this combination of Avibactam with ceftazidime as a combination therapy is due to the ability of avibactam to inhibit class A and C β-lactamases, including class Acarbapenemases (e.g., Klebsiellapneumoniaecarbapenemase (KPC)-2). This type of combination chemotherapy may also be considered in ceftazidime resistant *Burkholderiacepacia*

cases[9]. Ceftazidime-resistant *Burkholderiacepacia*; should also be considered as an important differential for the sepsis patient who initially presents with high grade fever with respiratory complaints; so that appropriate investigations can be performed in time to improve the treatment outcome.

Conclusion

The emergence of Ceftazidime resistant *Burkholderiacepacia* sepsis in patients, especially in a healthcare setting, poses a significant threat to our community. More and more cases infected with *Burkholderiacepacia* are being reported from our Institution and this pathogen is becoming an increasingly common source of infection in healthcare settings. Such type of pathogenic organism is also very difficult to diagnose using conventional diagnostic method. Availability of automated culture and sensitivity system in the hospital set up has improved the isolation and identification of such organisms. Getting the sensitivity pattern with minimum inhibitory concentration (MIC) is an added advantage for such pathogens. A high index of suspicion is required to diagnose and treat this pathogen to prevent fatal outcomes related to its disease course.

Knowledge, Attitude and Awareness of School Teachers Residing in Meerut District (UP) towards Oral Health of Children

Noopur Kaushik[1], Nikhil Srivastava[2], Vivek Rana[3], Priyadarshini Bhatia[4]

[1]Professor, [2]Principal, Professor and Head, [3]Professor, Department of Pediatric and Preventive Dentistry, Subharti Dental College and Hospital, Swami Vivekanand Subharti University, Meerut (U.P.), [4]Private Practitioner (Pedaitric Dentist), Karnal

Abstract

Context: School teachers by virtue of their training can influence a large number of children thereby play major role in the planning and implementation of oral health preventive programs.

Aims: To assess the knowledge, attitude and awareness of school teachers towards oral health.

Method and Material: This was a cross-sectional survey conducted among school teachers of the city of Meerut. A structured questionnaire was used and 215 teachers were assessed on their knowledge on oral health, attitude and practice regarding their personal oral health, attitude regarding oral health of children and status of oral health education at the schools.

Results: Though 97% of the teachers considered oral health as important as general health, but only 58% knew about the importance of fluoride . Also only 66% of teachers admitted that their school was prepared for any dental emergency and 54% teachers were unaware about avulsion.

Conclusions: The knowledge Regarding Oral Health amongst school teachers was fair. Oral health awareness modules should be incorporated in School curriculum .

Keywords: *Knowledge, Attitude, Oral Health, School Teachers.*

Introduction

Children are at a high risk for dental diseases predominantly dental caries. Hence, Oral health education and promotion is considered as a priority.[1,2] As children spend most of their time with teachers, they play a pivotal role in the growth of young minds.[3,4] As School education plays an important role in behavior shaping of children, many countries have introduced School Oral Health Education Programs in curriculum, thus incorporating self hygiene practices in children.[5]

School teachers, often looked up as role models for children, have proved to be the most influential in transmitting oral hygiene preventive measures in children. In response to the World Health Organization (WHO) guidelines in the year 1978, many countries utilized school teachers as health education promoters for school children, to serve as an alternate personnel in primary health care approach in combating preventable diseases.[6] Despite the willingness to impart general oral health education, they seem to lack formal basic training in oral health matters which will hinder the effectiveness of teachers role in promoting oral health.[7] So, adequate knowledge of teachers towards oral health is of great

significance so that they can impart that knowledge and instill a positive attitude towards maintenance of good oral health in the children.[8]

Against this background, this study was undertaken with the objective to assess the school teacher's knowledge concerning oral health and disease and their attitude towards dental emergencies.

Subjects and Method

A cross-sectional questionnaire study was conducted in Meerut which is situated in the eastern part of Uttar Pradesh. Ethical clearance was obtained to conduct the study. Permission to conduct the study was obtained from the concerned authorities. A sample of in service teachers was selected by simple random sampling procedure and each teacher was a unit for analysis. The sample of 215 teachers were selected from private and government schools. A questionnaire was framed in English language and distributed to school teachers by a trained dental personnel. The questionnaire was formulated to ascertain oral health knowledge of participants and their teaching experience.

The questionnaire included 12 questions which had 2 – 4 options to assess the knowledge of the school teachers regarding importance of oral health, etiology of decay, their prevention, role of fluoride, handling of dental emergency, awareness about a paedodontist and organization of dental camps in the school. After taking permission, questionnaires were distributed among teachers for assessing their oral health knowledge and oral hygiene practices. The teachers were asked to tick one option to each question. One of the investigators was always available during the completion of the questionnaire and the participants were encouraged to approach her whenever they needed clarification of any point.

Statistical Method: Descriptive statistics were obtained and means and frequency distribution were calculated. The data was analyzed using the Statistical Package for Social Science 21.0

Results: In the present study, the number of participants were 215 which included both male and female teachers averaging 32 years of age (Table 1).

The results revealed that 97% of the teachers considered oral health as important as general health, however only 54% were aware of a Paedodontist thus more awareness needed to be spread amongst school teachers regarding the various branches of Dentistry. Out of 215, 169 teachers (78.6%) considered primary teeth to be as important as primary teeth whereas 46 teachers (21.4%) considered them to be insignificant.

Table 1: Socio demographic characteristics of study population

Socio demographic characterstics	Frequency	Percentage
Gender		
Male	47	21.87%
Female	168	78.13%
Years of Teaching Experience		
0-5 years	137	63.42%
6-10 years	41	18.98%
11- 15 years	37	17.12%

71.6% teachers considered both bacteria and sugar to be a causative agent for caries, however, 13.5% and 9.8% considered bacteria alone and others to be a causative agent for caries respectively. The general consideration of school teachers is that tooth decay can be prevented by avoiding sweet, along with regular tooth brushing and regular visits to the dentist (75.8%), however only 24.2% considered tooth brushing alone in prevention of caries. 58.6% thought that fluoride helps in prevention of tooth decay, whereas 31.6% thought it had a role in prevention of gingival disease, 7% in prevention of malocclusion and according to 2.8% it had no effect on teeth.

Regarding dental facilities in school to handle emergencies, only 142 out of 215 were prepared, however 205 teachers admitted that there is a need for school to have its own dental clinic in school. As expected, awareness regarding avulsion was least and 54% of the teachers thought of throwing the avulsed teeth and only 46%(99) teachers thought of preservingit and giving to the dentist.

Discussion

This study presented a comprehensive view of the oral health knowledge, attitude and practices of school teachers representative of the Meerut city, India. According to the best of our knowledge it represents the 1st study of its kind among school teachers in Meerut (UP). Previous studies conducted on school teachers in other parts of India are indicative of the fact that there is need to improve their oral health education.

Around 78% of the school teachers in our study were females. This is in accordance with a study conducted by Kompalli et al, in which female accounted for 82 % of the study population.[9] The mean age of the teachers in our study is 32 years, which is in contrast to the study by Shodan et al [6], in which it was 40 years. Thus it can be revealed that teachers in our study had less experience.

Around 97% of the teachers were aware of the importance of oral health, however only 50 % knew about a paedodontist. Approximately 75% of the subjects had knowledge of the cause of dental caries namely bacteria and sugar. Around the same number also agreed that regular visits to dentist, regular brushing and avoidance of sweets reduce the incidence of. However this is in contrast with studies conducted by Nyandindi et al[10] and Khan et al [11], in which only 50% of the teachers had knowledge regarding cause and prevention of dental caries, thus the teachers in present study had knowledge regarding the causation and prevention of tooth decay .

Around 58.6% teachers know that fluoride protects against tooth decay. Thus Knowledge about fluoride could be shared with the Teachers in school, where kids have a higher incidence of dental caries. Thus It is the role of the dentist to impart basic preventive knowledge other than doing preventive measures alone. The results were low as compared to study by Shekhar et al [3], in which 74.5 % teachers had knowledge regarding Fluoride.

In cases of avulsion or complete tooth loss 46% of the teachers knew that it can be reimplanted, whereas 54% thought that it need not be stored or preserved and can be thrown. Though the direct or indirect experience of dental trauma to the teachers is not an uncommon phenomenon they had little knowledge regarding its prevention and immediate management and was in accordance with earlier studies.[12,13]

Schools are the place where children spend most of their time, thus school teachers are considered pivotal in educating children about oral health awareness and prevention programs. Not only this but children consider their teachers as their role models Hence, in the present study an effort was made to assess school teacher's knowledge, attitude and awareness regarding Oral health by means of self-administered questionnaire.

With the aim to utilize the potential of teachers, the dental profession should attempt to encourage the inclusion of the knowledge about oral-health, diseases, their method of prevention and oral-health promotion within the curriculum of school-teachers. In Indian scenario, it's been recommended in national oral-health policy[14] that, schoolteachers should be trained in giving Oral-health Education. Implementation of primary prevention package through the school health schemes in the different urban and rural areas. Regular oral-health promotional activities in form of health education, regular dental check-up, demonstration of brushing and rinsing technique and preventive and interceptive treatment can be undertaken at school level and 95.5% teachers in our study admitted that there should be a setup of dental clinic within school premises.

Oral health is as important as general health of an individual. Children need to be constantly monitored and shaped in all aspects of life. School teachers should emphasize about healthy eating habits and food in parent teachers meeting. Furthermore, it might be appropriate to include the oral health related message in daily routine teachings as a very recent Indian study has shown that schools where teachers were trained for health education, their children had significantly lower prevalence of dental caries and mean plaque index.[15] As, results in the present study showed medium knowledge among teachers regarding role of fluoride in dental decay and how to manage cases of avulsion in school, it can be improved by providing them accurate knowledge about oral-health and preventive measures.

Recommendations: The study should be conducted on a larger sample size and Pan India, in order to get the clear picture of knowledge, attitude and awareness of school teachers .

Conclusion

Oral health is as important as general health of individuals. Oral hygiene knowledge and awareness should be incorporated in children as early as possible and the best educators for them, apart from their parent, can be the school teachers as students consider them as their role model. In the present study teachers were aware of causative agent of dental caries, however they were unaware about the role of fluoride in caries prevention. The teachers had little knowledge regarding avulsed tooth and majority of them agreed for a dental clinic in the school premises. Hence, keeping this information as baseline data further educative and motivational programs can be planned and school curriculum should include school teacher training regarding oral health promotion and prevention . The change to healthy

practice can occur by giving enough education and motivation to the children[16].

Effect of Tabata Protocol on Exertion Level and Lower Limb Explosive Strength in Recreational Footballers: An Experimental Study

Omkar Ashok Somade[1], Prasannajeet Pramod Nikam[2]

[1]Intern, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences 'Deemed to be University', [2]Assistant Professor, Department of Sports Physiotherapy, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharahstra, India

Abstract

Purpose of the Study: To find the effect of Tabata protocol on exertion level and lower limb explosive strength in recreational footballers.

Materials and Methodology: Subjects fulfilling the inclusion and exclusion criteria were included. After taking consent from, the footballers were assessed for their exertion level and lower limb explosive strength using rate of perceived exertion scale(RPE) and vertical jump height (VJH).The footballers were then asked to perform 8 tabata exercises 4 times per week total duration of session is 4 weeks. Prior to tabata exercise the footballers had to do warm up and post exercise, cool down. The entire protocol was supposed to be performed before their practice. After 4 weeks, post assessment was taken for their exertion level using the RPE scale and lower limb explosive strength using VJH. Statistical analysis was done using the paired t -test.

Result: The statistical analysis showed considerable extremely significant improvement in RPE and VJH with p value <0.0001.

Conclusion: The above study concluded that On the basis of the result of the study, it was concluded that Tabata Protocol is effective treatment protocol on recreational football players. Lower limb explosive strength and exertion level was improved, both clinically and statistically.

Keywords: *Footballers, RPE, VJH, Lower limb explosive strength, Exertion level.*

Introduction

In the 1950s, high interval intensity training (HIIT) was introduced by Reindell and Roskamm.[1] High –intensity interval training is an exercise program characterized by relatively short bursts of vigorous activity, with periods of rest or low- intensity exercise for recovery.[2] Safe and effective high intensity interval training involves repeated exercise at a high intensity for 30 seconds to several minutes, with 1-5 minutes of recovery (either no or low intensity exercise) in between.[3,4] HIIT is relatively a difficult program for the subjects to perform. One of the merits of HIIT is that it is time efficient and enhances performance and improves overall health.These are identical to the benefits obtained from more traditional low-medium intensity, long duration continuous training [5,6,7]

Football, one of the most multifactorial sport requires an amalgam of body composition, strength, power, quickness, reaction time, speed, agility and endurance. [8]

Muscular strength training has increased available force of muscle contraction in appropriate muscle groups as a result of these explosive performances.[9,10] Use between both lower and upper limb decreases physical demand of the specific part of the body.[11]

Tabata is one of the best and effective HIIT method. It is time saving as well as Comparitively more intense[12]. The popularity of high intensity interval training has rised up in recent times. Tabatatraining, a kind of HIIT,was found out by Japanese scientist Izumi tabata in 1996. The session goes as follows,20 seconds exercise bouts,10 seconds rest and is continue for 4 minutes. Tabata training as grown up to include various exercises perform between the classic 20-10 pattern.[13]

Original Tabata Protocol:

Warm up -5 minutes.

Ultra high intensity exercise- 20 seconds

Rest- 10 seconds

Duration:- 4 minutes

No of Intervals-8

Cool down- 2 minutes [12]

Tabata protocol includes 20-minutes of exercises. It is divided into four segments. Each segments consist of 4 different exercises and It last for 4 minutes:-

1ST segment includes one minute of high knee run followed by plank punch for another one minute, Jumping Jacks for third minute and side skaters for last one minute.

2nd segment includes one minute of Jump Rope followed by In\out Boat for another one minute,Line Jumps for 3rd minutes and push-ups for last one minute.

3rd segment includes one minute of Burpees followed by Russian Twists for another one minute squats for 3rd minute and Lunges for last one minute.

4th segment includes one minute of Mt. Climbers followed by Push-ups for another one minutes Split-Squat for 3rd minute and Box Jumps for last one minute.[13]

Explosive Strength: In several studies, effect of HIIT on explosive strength (power) is examined using various jump tests. Explosive strength is the ability to attain maximal muscle contraction in short time. The jump tests used in assessment of lower limb are Counter movement jump (CMJ); drop jump (DJ); Standing broad (long)jump (SBJ); squat jump (SJ) and vertical jump (VJ).

Jumping ability is a useful assessment tool to assess explosive strength.[14] Thus, the motto of this study is to find out most effective treatment protocol in recreational football players. In this research, if tabata exercises are effective than this programme can be used as a routine treatment for professional footballers.

Materials and Methodology

After ethical clearance, the footballers were screened for their inclusion and exclusion criteria. Accordingly, 23 footballers were selected. For assessment of exertion level and lower limb explosive strength, RPE and VJH were used. The footballers were asked to perform exercises prior to their practice. The exercise protocol was as follows-

Warm-Up Exercises:

- Straight Leg March
- Butt Kicks
- Power Shuffle(Step Slide)
- Jogging with Squats.[15]

Tabata Protocol:

1. **Burpees:**
   - Feet shoulder width apart with hands by your side. 1st
   - Bend knees while pushing your hips back such that your body is in a squatting position.
   - Move into a squat position with your hands on the ground. 2nd
   - Kick your feet back into a plank position with your arms extended. 3rd
   - Return back to squat position such that your hands are on the ground. 4th
   - Jump up and extend your arms into the air.
   - Come back to standing position.
2. **High knee run:**
   - Stand tall with your legs shoulder apart.
   - Relax your upper body
   - Assume a running posture

- Run on the spot, such that you bend your knees as thighs you can (90-degree angle from your thighs to your ankle)
- Keep your hands relaxed, elbows bent and shoulder down while swinging your arms back and forth

3. **Push-Ups:**
   - Go in prone position.
   - Hands by your side at chest level.
   - Raise your upper body by keeping your legs straight with the arms extended.
   - Repeat lowering and raising at a steady pace out.
4. **Squat:**
   - Stand straight with feet shoulder-width apart
   - Bend your knees into a squat position.
5. **Mountain Climbers:**
   - Begin in plank position with your abs pulled in.
   - Bending right knee, bring it towards your arms while keeping the other straight.
   - Quickly bring the left knee forwards, simultaneously taking back the right one.
   - Continue to Switch Knees. Pull the knees simultaneously in a "running" motion
6. **Lunges:**
   - Stand with feet shoulder width apart.
   - Position one leg forward with knee bent and foot flat on the ground while other leg is positioned behind.
   - Repeat with the other leg.
7. **Side Skaters:**
   - Start in a small squat. Jump sideways to the left. Bring your right leg behind your left.
   - Reverse direction. This completes one rep.
8. **Jump Rope:**
   - Choose a rope that reaches upto your shoulders when it is folded in half.
   - Hold the rope's handle in each of your hand. extend your hand and forearm at a 45 degree angle.
   - Step over the rope.
   - Swing the rope over your head by moving your wrist.
   - Stand on your tip toes and when the rope is coming towards the front of your feet hop over it by pushing off the balls of your feet.[13]

Cool Down Exercises:

Standing Quadriceps Stretch

Standing Calf Stretch

Standing Hamstring Stretch

Seated Cross-Legged Gluteus Stretch.[15]

After a duration of 4 weeks, the footballers were again assessed for their exertion level and lower limb explosive strength using RPE scale and VJH. Statistical analysis was done using the paired t test and confirmed with instat software.

Results

1. Rate of Perceived Exertion Scale

Interpretation: The pre-intervention RPE was 11.913±2.109 and post intervention RPE was 8.783±1.906. The P value was<0.0001 which was statistically considered extremely significant (t=10.543) This shows improvement in Rate of perceived exertion scale.

The analysis was done using 'paired t test'.

2. Vertical Jump Height

Interpretation: The pre intervention VJH was 31.826±3.473 and post intervention was 34.957±3.140. The P value was<0.0001 which was statistically considered extremely significant (t=8.501)This shows improvement in Vertical jump height.

The analysis was done using 'paired t test'.

Discussion

The study Effect of Tabata protocol on exertion level and lower limb explosive strength in recreational footballers" was conducted to find out the effect of 4 minutes of Tabata protocol i.e., fat burning workout protocol. Football,one of the most multifactorial sport requires an amalgam of body composition, strength, power,quickness, reactiontime, speed agility and endurance.[8] The most common lower limb injuries

occur in ankle. The treatment plan is designed for patient to improve exertion level and lower limb explosive strength. Previous study shown that HIIT exercise has maximize strength gains without an increase in body mass.[16]

Football players lower limb strengthening is important because all activities done by lower limb. Recreational footballers are unaware of importance of exercise. The objectives of the study were to determine the effect of 4 minutes of tabata protocol.

The study was conducted in Karad. In this study 23 Samples Size Were taken. They were selected on their inclusion and exclusion criteria. Inclusion criteria was both male and female,15-21 age group. Individual who play football as a recreational activity for at least 1-2 hours/day. Exclusion criteria was any previous history of on -field/off-field injuries, any musculoskeletal or neurological disorders, any previous history of surgeries, Subject not willing to participate. A prior written consent was taken from football players. After which they assessed for exertion level and lower limb explosive strength using RPE scale and VJH.

Before giving the treatment, Pre test of RPE scale can be done with the help of 6 minute walk test. In this test ask the subject to walk 6 min in 100 meters yard and time should be noted with the help of Stopwatch and Pre test of Vertical Jump Height can be done by asking the Subject to stand on wall side and reach up as high as you can with the hand closest to the wall. Make note of how high you can reach. Stand little away from the wall and jump high as possible using both arms and legs to assist in projecting the body upwards. With the help of chalk mark a point, as high as you can reach. Pre values of RPE, VJH can be collected and treatment can be given.

Prior to the treatment Subject participates Warm up program program so as to prepare the body for activity therby preventing injuries. The most common means for pre-activity warm up is the static stretch. Warm –Up exercise include: Straight leg March, Butt Kicks, Power Shuffle, Jogging with Squats (total duration 5 min). [15]

Recreational footballers 4 minutes of tabata protocol given total duration 4 weeks.8 tabata exercises given to footballers as per guided.4 times per week treatment session can be done. Each exercise performed for 30 seconds.8 exercise include: Burpees, High Knee Run, Push Ups, Squat, Mountain Climbers, Lunges, Side Skaters, Jump Rope.[13]

This was followed by Cool down exercise given Cool down exercise include:-Standing quadriceps Stretch, Standing Calf Stretch, Standing Hamstring Stretch, Seated Cross-Legged Gluteus Stretch.(total duration 2 min)[15]

Post test can be done and Post values can be Collected. Pre and Post value Comparison can be done. Statastical analysis can be done with the help of Outcome measures Paired t-test can be used.

The results of the present study supported our hypotheses that tabata protocol improve exertion level and lower limb explosive strength . The mean RPE pre intervention was 11.913 which decreased to 8.783. The p value was found to be($p<0.0001$)which was extremely significant. The mean VJH pre intervention was 31.826 which increased to 34.957. The p value was found to be($p<0.0001$) which was extremely significant. This study showed that RPE ($p=<0.0001$) considered Extremely significant. VJH ($p=<0.0001$) considered Extremely Significant. The results of the present study show that footballers exertion level and lower limb explosive strength show substantial progression.

The present study was a relatively short training intervention (only 4 week) and Longer training intervention is needed to observe improvement of professional footballers.

A Study to Assess the Effectiveness of Stress Management Training on Stress among Mothers of Mentally Disabled Children

P. Vijayasamundeeswari[1], K.Sathiya[1], R. Poongodi[2]

[1]Lecturer, Department of Paediatric Nursing, [2]Asst. Professor, Department of Community Health Nursing, Sri Ramachandra College of Nursing, Sri Ramachandra Institute of Higher education and Research

Abstract

Background: The birth of a child with mental retardation could lead to deep impact on families, thus parents of children with special needs are facing more problems than parents of normal children which affect their psychological well-being[1,2]. The continuing care of children with mental retardation is often stressful for parents. Researchers have indicated that parents of children with mental retardation are generally at risk for a variety of emotional difficulties . Keeping this in view the investigator aimed to assess the effectiveness of stress management training on stress among mothers of mentally disabled children.

Method: 50 mothers were selected randomly based on the inclusion exclusion criteria. Quasi experimental design was adopted for this study. 10 session of 60 minutes stress management training was given to the mothers after the pre test.

Results: The findings of the study depicted an evidence of significant difference in the pre test mean score of 25.29 and post test mean score of 14.38 with mean difference 10.91. It was highly significant at $p<0.001$ level .**Conclusion :** stress management training is effective in improving mental health, stress and social interaction among mothers of mentally disabled children.

Keywords: *Stress management training, mentally disabled children.*

Introduction

The birth of a child with a disability affects the dynamic and interaction among family members which could leads to crisis within family. Specially issue of mental retardation in children is very serious because family with mental retarded children have problems in parental system, marital relationships, sibling relationships, even it affects their external system such as friend, family, neighbors, school and will cause more pressure within the system, at this point emotional state and physiological thoughts become abnormal then leads to vulnerability in cognitive activities which outcome of these behavioral problems will bring out depression and anxiety[3]. Regarding to this issues affiliates could internalize their stigma and affect their life, so they might face with contagious stigma which is complex phenomenon. The birth of a child with mental retardation could lead to deep impact on families, thus parents of children with special needs are facing more problems than parents of normal children which affect their psychological well-being[4,5]. This kind of birth is one of the most stressful events among individual's life .Some factors such as advances in medicine and technology, effect mental retarded children to live longer and

healthier. The continuing care of children with mental retardation is often stressful for parents [6].

The effects on family unit can be economic, social and emotional in nature. Researchers have indicated that parents of children with mental retardation are generally at risk for a variety of emotional difficulties.[7] The cumulative impact of daily hassles and difficulties in dealing with disabled children represent significant stressors that may subsequently affect parents and family functioning. In particular, a great deal of evidence points to associations between the severity and frequency of behavior problems of children with intellectual disabilities and parental stress and psychiatric problems such as depression and anxiety.[8]

Stress management increases the ability of individual in order to coping with stressful situation to reduce the level of stress. This method of intervention consist of elements such as raising awareness about stress, relaxation training, identifying inefficient thoughts, cognitive restructuring, problem solving, anger management, self management and planning activities[9] interventions are necessary because the level of psychological well-being of parents directly associated with positive and effective interaction between them[10]. Keeping this in view the investigator has taken up this study to assess the effectiveness of stress management training on stress among mothers of mentally disabled children.

Conceptual Framework: The conceptual framework for this study was adopted from Ernestine Wiedenbach's "THE HELPING ART OF CLINICAL NURSING" (1964). Wiedenbach's model focuses on the concept of implementing need based care.

Method

The Sample and Sampling Present study is quasi-experiment designed as pre-test and post-test with control group. Samples consist of all parents with mental retarded children from city of Chennai, Quasi Experimental design was adopted for this study. population was mothers who attended vidhya sudha special school and the sample size was 50 mothers that were selected by purposive sampling technique .

Research Tools: It has three sections.

Section A: Consists of Demographic variables of mothers, age education, income,occupation and place of residence .

Section B: Consists of Demographic variables of Demographic variables of child age, sex of the child and diagnosis of the child

Section C: Parental Stress Scale by Berry and Jones (1995) . It has 18 item self report 5 – Point scale (strongly disagree, disagree, undecided, agree, strongly agree.)

Score Discription: Parental stress score items 1, 2, 5, 6, 7, 8, 17 and 18 should be reverse scored as follows: (1=5) (2=4) (3=3) (4=2) (5=1). low score to signify a low level of stress and a high score to signify a high level of stress. Overall possible scores on the scale range from 18 – 90. The higher the score the higher the measured level of Parental stress

Sampling criteria:

Inclusion criteria:

- Mothers with mentally disabled children
- between the age group of 20 to 45 years.
- Who come regularly to school
- who are willing to participate in the study

Exclusion Criteria:

- Who cannot understand and follow Tamil or English.
- Who have severe mentally disabled children.
- Who have undergone any complementary therapies

Introducing the Intervention Program: After running the pre-test on the both groups, experimental group attended in stress management program by using cogni- tive-behavioral method and after intervention, test scores were collected. Program of stress management by using cognitive- behavioral method includes 10 session of 60 minutes was performed as follows: In general, each session consists of two parts, first steps contains techniques of stress management and second part includes relaxation exercises.

First Session: Describe the factors of causing stress, response to factors of causing stress, awareness of the physical effects of stress and its possible consequences on health-muscle relaxa- tion for 16 groups of muscles.

Second Session: Stress and awareness (of automatic thoughts and physical sensations)—muscles relaxation for 8 muscles.

Third Session: Describe the relationship between

thoughts and emotions-diaphragmatic breathing, muscle relaxation for 4 groups of muscles.

Fourth Session: Identification of negative thinking and cog- nitive distortions-breathing, illustration and passive muscle re- laxation.

Fifth Session: Replacement of logical thoughts—Self-training for being heaviness and heat.

Sixth Session: Learn to deal effectively—Self-training for heart rate, respiration, abdomen and forehead.

Seventh Session: Implementation of effective coping re- sponse—Self-training with illustration and self-induction.

Eighth Session: Anger management training and mantra me- ditation.

Ninth Session: Gary expresses training—Counting breath meditation.

Tenth Session: Social Support—Overview of program and personal stress management program.

The presentation of material in each session was first to re- view the material of last meeting, then materials of that session were presented and at the end of that session the new materials were reviewed and finally new task has been given to them. After completing program, post-test were administrated to both groups in order to determine the level of stress

Results

Table 1: Frequency and Percentage Distribution of Mothers According to Demographic Variables (N=50)

Discussion

A family who has a child with an mentally disabled, experiences many challenges such as repeated physical and emotional crises, interactive family issues, ruined schedules and additional expenses, which can create financial burden and emotional distress for a family. Having a child with mentally disabled often requires a reorientation and reevaluation of family goals, responsibilities and relationships[11,12]. A significantly high proportion of parents of children with mentally disabled depression or both, needing mental health

services and support. Nearly 60% of the mothers were moderately depressed . In a study done in Turkey, Firat et al. reported high rates of depression in mothers of children with autism (72.5%) and in mothers of children with mental retardation (44.7%)[13]. The high level of stress or mental health problems experienced by parents of children with mentally disabled could be related to subjective factors such as feeling social isolation and life dissatisfaction[14],[15].

Parents of these children may struggle with a multitude of emotions interchangeably over years and often have feelings of guilt that somehow they caused the child to be disabled, for logical or illogical reasons [16].Other factors related to parenting a child with an mentally disabled that may negatively impact parent mental health may include disappointment that their child will not reach the career ideals they had envisioned or feelings of embarrassment, shame and isolation. .

Conclusions

There was a high rate of stress among parents of children with mentally disabled in this study. Mental health providers need to be aware of these issues, so appropriate mental health screening can be utilized among the care givers of children with mentally disabled.

Educational activities for parents on parenting a disabled child, the availability of services and how to utilize them. All these services should start once the mentally disabled child is born to help the parents in coping and should be extensively provided form others at more risk to develop psychiatric morbidity, such as mothers of children with multiple disabilities and chronically ill, as well as mothers of more than one disabled children and those with preschool age disabled children.

Acknowledgements: The authors are grateful to the mothers of mentally disabled children at special school who took time to participate in this study. Authors' also thank the management for giving the opportunity to conduct the study.

Financial or Other Competing Interests: This research paper was presented and won the best paper award in the 18th Annual National Conference of ISPN-2019 at Tezpur, Assam.

Conflicts of Interest: There are no conflicts of interest.

Ethical Clearance: Got from intuitional ethics committee (No- IEC-PhD/12/RR/2012).

Etiological Factors of Failure in Endonasal Dacryocystorhinostomy

Tripti[1], Abhay D. Havle[2], Ganesh M. Vihapure[3], Swapna A. Shedge[4]

[1]Resident, [2]Professor, [3]Asst. Professor, Department of Otorhinolaryngology, [4]Asst. Professor, Department of Anatomy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, 415110; Maharashtra, India

Abstract

Background: External dacryocystorhinostomy was first performed by Addeo Toti in 1904. Before, in 1893 Caldwell did mention about endonasal approach in lacrimal surgery. In 1989, the first endonasal dacryocystorhinostomy (DCR) performed by McDonogh and Meiring. The knowledge about etiological factor of failure of DCR would immensely help in its prevention.

Aim: To find out the causes of failure of endonasal DCR.

Materials and Method: All the cases having epiphora following endonasal DCR surgery which completed minimum one year period irrespective of their gender were included in the study. A total of 50 cases from otorhinolaryngology and ophthalmology having epiphora were enrolled in the study. All cases were subjected to diagnostic as well as therapeutic endoscopy using '0' degree endoscope, causes like deviated nasal septum, intranasal synaechia, cicatricial closure as well as inadequate size or non- dependant position of neo-ostium, inadequate sac marsupialization, etc. leading to failure were searched and corrected. All cases were followed for six months.

Results: There were 12 male and 38 female, epiphora was commonest symptom in all cases and the least common was redness and swelling of eyelid in 1.The most common etiological factor for failure of endonasal DCR was inadequate ostium size in 41, followed by inadequate sac marsupialization in 31, cicatricial closure of ostium in 26, intranasal synechia and ostium malposition in 18 each, ostium stenosis in 13, common canalicular obstruction in 11 and deviated nasal septum in 8 cases.

Conclusion: The most common aetiological factor responsible for failure of endonasal DCR was inadequate ostium size whereas; the least common was malpositioning of neoostium. The number of female having failed DCR was more than three times higher than male.

Keywords: *Endoscopy,Lacrimal apparatus, Lacrimal duct obstruction.*

Introduction

Endonasal dacryocystorhinostomy (DCR) is procedure for obstruction in lacrimal drainage system by way of nasal approach, with the help of a nasal endoscope. In 1904 the surgical modality by way of external dacryocystorhinostomy was first performed by Addeo Toti.[1] Before, in 1893 Caldwell mentioned endonasal approach in lacrimal surgery but due to narrowness of cavity it did not come in to practice.[2] With the development of the rigid fiberoptic endoscope the first modern endonasal endoscopic DCR procedure

was described by McDonogh and Meiring in 1989.[3] Various causes of its failure are known like obstruction of the nasal ostium, canalicular obstruction, functional epiphora, granuloma formation in the nasal ostium etc. The precise knowledge of such causes would immensely help in prevention of failure in endoscopic DCR.

Objective: To find out the causes of failure of endonasal DCR.

Materials and Method

All the cases having epiphora following endonasal DCR surgery which completed minimum one year period, irrespective of their gender were included in the study. All pregnant or lactating mothers, previous nasal injury at ostium site, neoplastic lesions of nose and lacrimal apparatus and known cases of immunodeficiency were excluded from the study.

A total of 50 cases from otorhinolaryngology and ophthalmology OPD of tertiary care teaching hospital, as per set inclusion and exclusion criteria and willing to participate were enrolled in the study. In all cases demographic characteristics, clinical history and past medical history etc were recorded. The nose and eye examination for any obvious deformity, turbinate hypertrophy, nasal polyposis, watering or purulent discharge in the medial canthal area etc. was carried out in all cases. Regurgitation on pressure over lacrimal sac (ROPLAS) test was done in all cases for diagnosis of nasolacrimal duct (NLD) block. Also probing and syringing was carried out for testing the patency of tract. Further, all cases were subjected to imaging and laboratory tests like dacryocystography, CT-PNS and routine CBC, BT, CT, PT, urine, BUN, creatinine and blood sugar. Both diagnostic as well as therapeutic nasal endoscopy was performed under anaesthesia using '0' degree endoscope in every case. Diagnostic nasal endoscopy (DNE) was done to note various etiological factors in nasal cavity like, deviated nasal septum, intranasal synaechia and non- dependant neo-ostium of previous surgery. At revision endoscopy as a part of corrective surgery additional causes like inadequate size of ostium, inadequate sac marsupialization, cicatricial closure of ostium etc. leading to failure were searched and corrected. After revision surgery during immediate follow up the crust were looked for and removed. Patency check of new stoma was made in all cases by syringing weekly for 1 month, monthly for 3 months and then at 6 month.

Statistical Analysis: Using statistical analysis the frequency distribution of collected data was obtained with the help of SPSS (Statistical Packaging for Social Sciences) IBM, INDIA software version 22.0.

Observation and Results

Amongst 50 cases, there were 12 male (24%) and 38 female (76%) in the ratio of 1: 3.16. All study participants were between age group of 20-70 years (table-1). Most of the cases 15 (30%) were of age between 51-60 years and the least 5 (10 %) belonged to the age group of 20-30 years. Amongst all cases the commonest presenting symptom (table-2) was watering of eyes in 50 (100 %), followed by pain in lower corner of the eye in 38 (76 %), swelling at medial canthus in 33 (66 %) and lacrimal abscess in 2 (4%) cases, whereas the least common symptom was redness and swelling of eyelid consequent to preseptal cellulitis in 1 (2%) case. In all cases using dacryocystography and CT-PNS the cause of failure noted was common canalicular obstruction, deviated nasal septum in 11 (22%) and 8 (16%) cases respectively while in 31 it could not be ascertained. At DNE in all cases of revision endonasal DCR the most common etiological factor for failure noted was inadequate ostium size in 41 (82 %), followed by inadequate sac marsupialization in 31 (62 %), cicatricial closure of ostium in 26 (52 %), intranasal synechia and ostium malposition in 18 (36 %) each, ostium stenosis in 13 (26%) -(table-3). The mean duration between first surgery and revision surgery amongst all cases was 5.08 years ± 2.23 years. The mean duration of symptom free period between two surgeries was 8.42 months ± 3.38 months.

Table 1: Age wise distribution of cases.

Years of Age	Number of subjects	Percent
20-30	5	10
31-40	9	18
41-50	10	20
51-60	15	30
61-70	11	22
Total	**50**	**100**

Table 2: Distribution of cases according to their symptoms

Signs and Symptoms	Number of Cases	Percent
Watering of eyes	50	100
Local pain	38	76
Swelling of medial canthus	33	66
Lacrimal abscess	2	4
Redness and swelling of eyelid	1	2

Table 3: Distribution of cases according to Causes of failed DCR

Causes of failed DCR	Number of Subjects	Percent
Cicatricial closure of ostium	26	52
Common canalicular obstruction	11	22
Intranasal synechia	18	36
Ostium stenosis	13	26
Deviated nasal septum	8	16
Inadequate ostium size	41	82
Ostium malposition	18	36
Inadequate sac marsupialization	31	62

Discussion

This study of failed DCR cases stressed up on finding different etiological factors such as opening of ostium, site of ostium, various other intranasal and septal pathologies. In study by Dave TV et al the majority of the cases are females 66.6% and males 33.3%.[4] and in the study of Baek JS et al, out of the total 61 cases, 46 are female i.e. 75% of the sample and the overall mean age is 54 years.[5] The percentage of gender distribution of participants in this study was 24 and 76% amongst male and female respectively in the ratio of 1: 3.16. The majority of the study participants belonged to the age group of 51-60 years i.e. 15(30%) and the least in 20-30 years i.e. 5 (10%). Dacryocystitis is more common amongst females due to narrow lumen of the bony canal and it often results in partial or complete closure of the NLD.[6] Acute dacryocystitis is more common in 5th decade.[6] Acute dacryocystitis presents with complaints of local pain, watering and purulent discharge from eye, swelling of the lacrimal sac region and occasionally there may be pre septal cellulitis and lacrimal abscess. In the similar study by Dave et al the epiphora is commonest presentation in 100% of cases.[4] The study by Goyal R et al, persistent watering from affected eye in 44 cases, regurgitation of pus from sac in 34, mucocele in 18 and pyocele and fistula formation in 8 each.[7] In majority of the cases of this study the clinical presentation was epiphora in 50 (100%) and it was in accordance with above two studies, pain in lower corner of the eye in 38 (76%), swelling at medial canthus in 33 (66 %) and lacrimal abscess in 2 (4%) cases, whereas the least common was redness and swelling of eyelid consequent to preseptal cellulitis in 1 (2%) case. In study by Dave TV et al, majority of previous DCR cases are having inadequate ostium size (82%), commonest cause of failure is insufficient osteotomy 85.1% followed by inadequate marsupialization of sac 77.7% and cicatricial closure of the ostium 55.5%.[4] In this study the causes leading to failure of DCR were inadequate ostium size in 41 (82 %) cases, followed by inadequate sac marsupialization 31 (62 %), cicatricial closure of ostium 26 (52 %) and it was in accordance with above two studies. Further, in this study the intranasal synechia and ostium malposition in 18 (36 %) each, ostium stenosis 13 (26%), common canalicular obstruction 11 (22%) and deviated nasal septum 8 (16%) were the additional causes.The study conducted by Choussy et al revision endoscopic DCRs in 17 patients and reported ostium scarring in 13 (76.47%) patients and improper ostium site in 3 (17.64%) patients.[8] In this study the commonest cause of failure was inadequae ostium size in 41 (82%) cases.Hull et al in their study of failed endonasal DCR found 14 (74%) cases with failure due to ostium blockage as a result of scarring and the least common cause was high ostium 1(5%).[9]

In study by Goyal R et al, the patency of NLD is 85.10 %, whereas, partial block and clear fluid regurgitation in 06.38 % during 12 months follow up after surgery. In this study the NLD patency was confirmed by sac syringing at all follow ups after 1 week, 1 month and 3 months and 6 months post-operatively. Our findings was not in accordance with the study by Goyal R et al which could be due to almost double the period of follow up and sample size in their study.[7] In the study by Goyal R et al, during follow up over period of 1 year amongst their cases the complications are scarred and fibrosed ostium in 08, intranasal synechia formation in 07, ostium site granuloma with narrowing in 06, whereas common canalicular duct obstruction in 1.[7] Amongst all cases in this study, intra-operative complication were hemorrhage in 4 (8%), post-operative epistaxis 3 (6%) and local infection in 1(2%). However, no such complications mentioned by Goyal R et al were noted in this study.

Amongst 31 out of 50 cases of failed endonasal DCR in this study at dacryocystography and CT-PNS

the cause of failure could not be ascertained whereas, the common canalicular obstruction, deviated nasal septum was found in 11 (22%) and 8 (16%) cases respectively.

Conclusion

The aetiological factors responsible for failure of endonasal DCR noted being many, the most common noted in this study during DNE was inadequate ostium size in 41 (82%) followed by inadequate marsupialization of sac 31 (62%), cicatricial narrowing of ostium 26 (52%) and intranasal synechia and ostium malposition in 18 (36%) each, ostium stenosis in 13 (26%). The pre-operative dacryocystography and CT-PNS per say in failed cases of DCR could not ascertain the cause for failure in 31 (62%) cases. The total number of female having failed DCR was more than three times higher than male (F: M -3.16 : 1).

Summary: The commonest aetiological factors for failure of endonasal DCR in this study was inadequate size of ostium followed by inadequate marsupialization of sac, cicatricial narrowing of ostium and intranasal synechia around ostium site whereas, the least common was malpositioning of neo ostium. The total number of female having failed DCR was more than three times higher than male. The findings of the present study suggests preoperative work up like paranasal sinus-CT scan and dacryocystography should be routinely undertaken for discovering the intranasal structural abnormalities so that the failure rate of endonasal DCR can be minimised. Meticulous endoscopic evaluation must be included as a part of preoperative work up in all cases for preventing failure of DCR.

Acknowledgements: We sincerely thank the departments of ophthalmology, radiology and anesthesiology for their cooperation during management of cases in this study. We are thankful to institutional research department for rendering financial support during the study.

Conflict of Interest: None.

This study was undertaken after prior ethical clearance from institutional ethics committee, vide letter No. KIMSDU/IEC/03/2017 dated 23/11/2017.

Cerebellar Dysfunction a Rare Complication of Dengue

Bharat Bhushan Singh[1], Gurnoor Singh[2], Divya Nijhawan[3]

[1]Junior Resident, [2]Junior Resident, Department of Pediatrics, [3]Junior Resident, Department of Radiodiagnosis, Maharishi Markandeshwar Institute of Medical Sciences and Research, Maharishi Markandeshwar (Deemed to be) University, Mullana, Ambala, Haryana

Abstract

Dengue is a benign syndrome caused by several arthropod-borne viruses transmitted to humans by aedes aegypti mosquito. Clinically the disease may present as mild viral fever which may get complicated by the development of hemorrhage and shock. Involvement of liver, kidney and other organs are well known complications of dengue. In recent times due to modification in virological properties of dengue virus an increased number of neurological complications are increasingly reported. CNS manifestations in dengue are rare but can have deleterious complications like encephalopathy, meningitis, cranial nerve palsy, post infectious acute disseminated encephalomyelitis, cerebellar syndrome and transverse myelitis. Here we present a case of Cerebellar dysfunction, a rare complication of dengue.

Keywords: *Dengue fever, neurological manifestation,cerebellar dysfunction, neuroimaging in dengue.*

Introduction

Dengue fever is an arboviral infection, commonly transmitted to humans by Aedes aegypti mosquito. Globally 50 million dengue infections are reported annually. According to the WHO case fatality rate of dengue is 5%.[1] Clinically the disease presents as common viral fever which gets complicated with the development of bleeding manifestation and shock. CNS involvement in dengue infection was thought to be less common. However, in recent years neurological manifestations of the dengue infection have been increasingly reported but their exact incidence remains unknown. Neurological manifestation has been reported in the 25 countries spanning all the continents and involving the age group from 3 months to 60 years.[2] High body temperature, elevated hematocrit, thrombocytopenia and transaminitis are reported to be independent risk factors for neurological complications.[3] Autoimmune reaction and metabolic alterations has been demonstrated in most neurological complication of dengue fever cases. Common neurological complaints in dengue fever include complications due to involvement of the central nervous system like encephalopathy, meningitis, cerebellar syndrome transverse myelitis and due to involvement of peripheral nervous system such as GBS, hypokalemic paralysis and myositis.[4] Here we present a rare case of dengue infection with cerebellar involvement.

Case Summary: A 15-year-old female child was admitted to PICU at MMIMSR, Mullana (Ambala) with a history fever for 5 days, vomiting and melena for two days with active nasal bleed at the time of admission. The patient was referred from a nearby private hospital as a case of fever with thrombocytopenia with Hb 9.8g%, PCV 45%, TLC 2300 cells/mm^3 (48% PMN) and platelets 45000 cells/mm^3. On examination, the patient was hemodynamically unstable with tachycardia, feeble pulses and hypotension.The patient was conscious of GCS 15/15 and no signs of meningeal irritation. The patient was probably kept under-diagnosis of dengue shock syndrome, i/v lines were established samples were

Corresponding Author:
Gurdeep Singh Dhanjal
Professor, Department of Pediatrics, Maharishi Markandeshwar Institute of Medical Sciences and Research, Maharishi Markandeshwar (Deemed to be) University, Mullana, Ambala, Haryana

sent. The patient was treated as per the WHO guidelines of Dengue shock syndrome. The patient responded well to fluids. Blood investigations of child showed Hb 9.1 gm%, TLC 4600 cells/mm^3 (54% PMN), Platelets 30000 cells/mm^3, transaminitis (SGOT 566 IU/dl and SGPT 205 IU/dl), CRP 37mg/L, Dengue Serology positive for NS1 antigen, Ig M and IgG. After the patient was hemodynamically stable complete neurological examination was done which revealed signs of impaired cerebellarfunction i.e. patient was not able to perform dysdiadochokinesia, finger-nose test and finger-finger nose test. The patient had ataxic gait, pendularknee jerk and micrographia. CEMRI showed features of dengue encephalitis with marked diffuse restriction in frontal parasagittal region, midbrain, right cerebellar folia and punctate hyper-intense foci in subcortical white matter and more in the frontal region.

Figure 1: DWI axial view showing diffusion restriction in high frontal parasagittal region

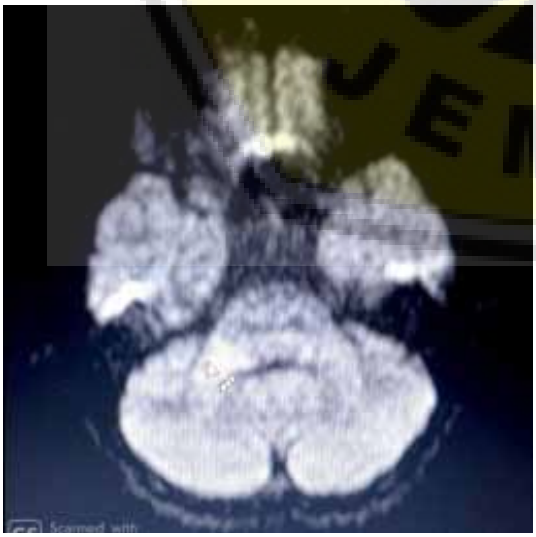

Figure 2: DWI axial view showing marked diffusion restriction right cerebellar folia

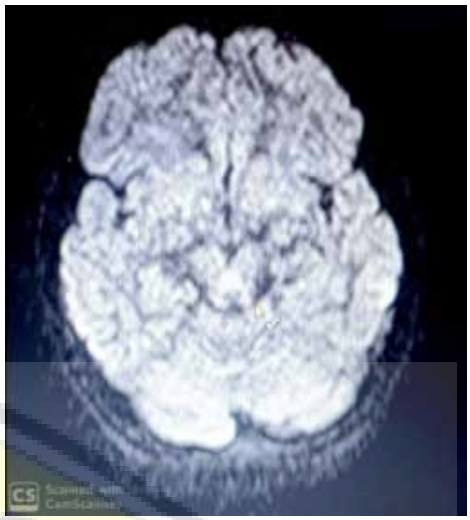

Figure 3: DWI axial view showing diffuse restriction in midbrain

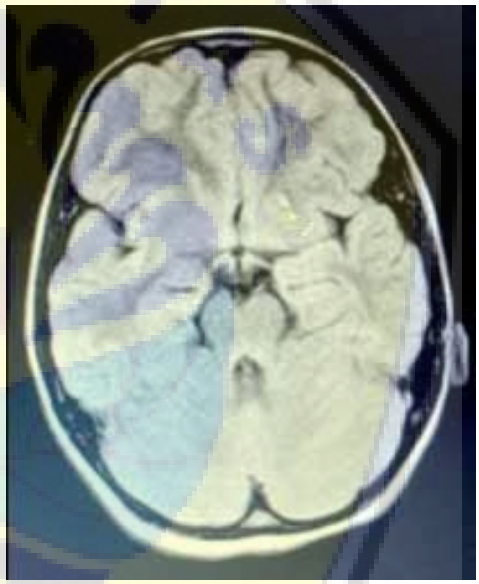

Figure 4: Flair axial image showing small punctate hyper-intense foci in subcortical white matter and more in the frontal region.

Lumbar puncture showed five cells, Glucose 140mg/dl and protein 82 mg/dl. CSF culture was sterile.

The patient was regularly monitored for progression of symptoms patient was discharged on the 10^{th} day of hospital stay with improvement in cerebellar function and advised follow up. The patient came in OPD after two weeks with further improvement in cerebellar function.

Discussion

With the availability of better imaging tools, neurological complication and its neuroimaging

evidence of dengue fever are increasingly reported. Dengue fever may lead to neurological complications involving both the central nervous system and the peripheral nervous system. A possible mechanism of neurological complication in dengue has been proposed due to direct invasion of the virus, autoimmune reaction and metabolic alterations. Weeratunga et al in 2014 have described cerebellar syndrome in dengue consisting of bilateral vertical and horizontal nystagmus with dysarthria bilateral limb and gait ataxia with normal CSF and hyperdense lesion on MRI. Low-grade inflammatory response was proposed as the cause of cerebellar symptoms.[5] A study done by Vinay et al on neuroimaging of 8 dengue cases had found cerebellar involvement in all the cases. Involvement of the brainstem was noted in four cases, thalamus in six cases, basal ganglia in two cases, internal capsule in three cases, insula in one case with frontoparietal regions being most commonly involved.[6] Varicella-zoster, Epstein Barr virus, mumps, measles and rubella are other important causes of acute cerebellar involvement.[7] Patel et al have also reported a similar case of cerebellar involvement along with dengue.[8] Our case presented with a sign of cerebellar dysfunction with clinical, lab investigations suggestive of dengue and MRI findings suggestive of dengue encephalitis.

Conclusion

Our case reports one rare case of cerebellar dysfunction in dengue which will help in the widening spectrum of neurological complications of dengue. Detailed neurological examination should be done in severe cases of dengue so that neurological manifestation is not missed.

Ethical Clearance: Consent taken from parents of case.

Empathy and Interpersonal Relationship among Institutionalized Children

Jincy V.V.[1], Suja M.K.[2]

[1]Ph.D. Scholar, [2]Associate professor, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Abstract:

Background: The arena of child vulnerability is taking complex shapes in the new socio-cultural situations .Institution children are those who deserve special care and attention in order to fulfil their basic and secondary needs both with equal importance, which later on make an impact if it's not satisfied. As humans are called as social being there are some expected qualities which makes us to be connected with each other in appositive way both in family and society. Empathy thus makes the people to be connected which further leads to form an interpersonal relationship.

Aim: The aim of the study was to assess the level of empathy among the participants and to assess the level of interpersonal relationship also the correlation between empathy and interpersonal relationship among institutionalised children.

Materials and Method: A total of 214 subjects aged 12-18 years were selected for study based on lottery method of Simple random sampling. The study was based on the Questions pertaining to socio-demographic profile of age, gender, mother tongue,good friendship in the institution, educational qualification, situation before being in the institution, interest in education and time period for being in the institution. The data collection was done in an interview schedule. The standardised tool used in the study was, the Self-esteem scale developed Life Skills Assessment Scale (LSAS) by A. Radhakrishnan Nair, R. Subasree & Sunitha Rajan.

Results: The result shows that there is significant difference between the variable, having good friendship in the institution and Empathy also there is a positive correlation between Empathy and Interpersonal relationship.

Conclusion: The result led to a conclusion that both empathy and interpersonal relationship has a common feature as both has difference in level of measurement among children by analysing its level through different socio demographic variables also there is a correlation between Empathy and Interpersonal relationship.

Keywords: *Empathy, Interpersonal relationship, Institutionalized children.*

Introduction

A study with focus on child institutionalization deserves higher research attention due to the fact that there are a growing number of children who are being seeking this service. The arena of child vulnerability is taking complex shapes in the new socio-cultural situations .Institution children are those who deserve special care and attention in order to fulfil their basic and secondary needs both with equal importance, which later on make an impact if it's not satisfied. Interpersonal relationship is a process which grow and develop throughout our life which forms its basement during the first few years

Ph.D. Scholar, Department of Social Work, Amrita School of Engineering, Coimbator, Amrita Vishwa Vidyapeetham, India
e-mail: jincyjo11@gmail.com

of child's life and later enrich in different stages of developments .Interpersonal relationship is a process which extends in wide range which has to start from ones very close circle such as family, dears and nears and extends to society. As humans are called as social being there are some expected qualities which makes us to be connected with each other in appositive way both in family and society. Empathy and interpersonal relationship can be called as the basic element among them .Empathy always helps to be connected with others and as a result the tendency of caring will also be developed.[1] Empathy thus makes the people to be connected which further leads to form an interpersonal relationship.

Materials and Method:

This is a descriptive research conducted among 214 children from different Institutions for Children at Kannur district .Kerala, India. The samples selected for the study were under the age group of 12-18 years. The sampling technique adopted for the selection of the respondent subjects was by lottery method under Simple random sampling method.

The tool of data collection used for the study was an interview schedule that included questions pertaining to socio-demographic profile and standardised Life Skill Assessment scale developed by A. Radhakrishnan Nair, R.Subasree & Sunitha Rajan[2]. Among the 10 components of life skill the components empathy and interpersonal relationship was assessed, the component empathy and interpersonal relationships have 11 items each.

Statistical Analysis: ANOVA Test for Comparing Empathy and interpersonal relationship score is based on educational qualification, situation before being in the institution, interest in education and time period for being in the institution. The independent sample T-test was used to compare Empathy and Interpersonal relationship with age, gender, mother tongue and about good friendship in the institution. Chi-Square Test was used to test the correlation between Empathy and Interpersonal relationship.

Result

The Empathy score was compared by with educational qualification, situation before being in the institution, interest in education and time period for being in the institution by using ANOVA (Table-1). The independent sample T-test was used to compare Empathy with age, gender, mother tongue and about good friendship (Table-2). The empathy score was high among male children,children who are 12-15 years old, children who are in secondary schools, whose mother tongue is Malayalam, those who were studying before being in the institution and those who are interested in studies, also among the children those who are being in the institution for1-5 years and the children those who are having good friendship in the institution. There is a significant difference between the variables having good friendship in the institution and Empathy

	No	5	36.60	6.02			

Table 5: Correlation between empathy and interpersonal relationship

Chi-Square Test:

		Interpersonal Relationship						Total	
		Low (<= 30)		Moderate (31-36)		High (>=37)		No.	%
		No.	%	No.	%	No.	%		
Empathy	Low (<= 29)	17	31.5	30	55.6	7	13.0	54	100.0
	Moderate (30-35)	25	24.8	59	58.4	17	16.8	101	100.0
	High (>=36)	10	16.9	30	50.8	19	32.2	59	100.0
Total		**52**	**24.3**	**119**	**55.6**	**43**	**20.1**	**214**	**100.0**

Interpersonal relationship was compared with educational qualification, situation before being in the institution, interest in education and time period for being in the institution by using ANOVA (Table-3). The independent sample T-test was used to compare Interpersonal relationship with age, gender, mother tongue and about good friendship in the institution (Table-4). There is no significant difference between any of the variables and interpersonal relationship. But the interpersonal relationship score was high among children under the age group 12-15, among boys, those who are in secondary school, children whose mother tongue is Malayalam, those who were studying before being in the institution and those who are in interested in studies, also the interpersonal relationship is high among the children those who are being in the institution for 1-5 years and the children those who are having good friendship in the institution.

The correlation test also agrees that there is a positive correlation between empathy and interpersonal relationship. The children who have low level of empathy are also having low level of interpersonal relationship. Those who are having moderate level empathy shows moderate level of interpersonal relationship and children having high level of empathy shows high level of interpersonal relationship, which is significant at 1% (Table-5).

Discussion

Mathies Allemand et al in their study states that during adolescent years there is a tendency of increase in empathy, the present study shows that there is no significant difference between empathy and age even though among 1-18 years old children who are 29% among total respondents and other children who are below that also having same level of empathy[3].

The present study shows that female children are empathetic than male children, which comes only 45% among total respondent,Loren Toussaint and Jon R. Weeb In their study among 127 respondents states that females are more empathetic than males[4].

Suk Chun Fung in his study states that education is a significant factor of humans empathy same as this in the present study also the respondents having empathy are secondary school children (53%) comparing with primary school children[5].

The present study shows that the empathy is comparatively less among the children who were wandering (13%) before being in the institution than those who were working (2%) and studying (84%), this result shows that the children who are not getting proper parental care, love and attention without fulfilling their basic needs are lacking empathy as emphasised in the study of Paulina Akpan-Idiok and Aniebietabasi in their study which states that family type, good parenting and home atmosphere influences child's social adjustment[6] .

Ravneet Kaur et al in their study states that the children who were being in the institutionalised for 1-5 years have more empathy but in the present study the children who are having empathy are those who are institutionalised for above 10 years, the respondents who are being in the institution more than 10 years are only 18% among total respondents[7].

Aarti Thakkar et alin their study states that compared to the attachment of institutionalised children between their inmates, care givers and mentors, it shows that the

children are more attached and have understanding with their inmates as like in the present study the children those who don't have good friendship in the institution have empathy than those who have good friendship in the institution, that's only 2% among total respondents[8].

According to the present study all the children are having moderate level of Interpersonal relationship, which can be supported by the study of Kim Maclean et al which states that even though less optimal development which includes intellectual, physical, behavioural and social development, which is one of the risk factor of institutionalisation, it may not lead a child to psychopathology during their process of development[9].

The present study shows that both male(55%) and female(45%) children have, interpersonal relationship, Rebecca A .Colman and Cathy Spatz Widom in their study states that during adulthood both males and females are incapable to form a healthy interpersonal relationship as they were exposed to physical abuse or neglect during their childhood[10].

The present study shows the result, higher secondary school students (30% of the respondent)have interpersonal relationship than secondary and primary school students,which can be supported by the study result of R.Steve Mc Callum and Bruce A, Bracken which states that there is a increased risk of dropping out of school,criminality and even marital maladjustment among children who are having poor interpersonal relationship which means once the interpersonal relationship is developed the rate of adjustment problems also decrease thus they continue the education[11].

The present study says that the children who were wandering and working before coming to the institution have interpersonal relationship than the children (84%) who were studying before being institutionalised have interpersonal relationship but in the study of S.N .Maduet al which states that as the street children have lower purpose in life the quality of interpersonal relationship is also low than non-street and part –time non street children[12].

David Zandvliet et al in their studies concluded that the self-interest of the students in learning is promoted by among students once they feel they are connected with their teachers which makes them to believe that they are competed and experience and thus they experience a substantial support of autonomy from their teachers, in the present study also as mentioned in the above study majority the children who are interested in studies or to get training in any type of vocation have interpersonal relationship than those who are not interested in studies[13].

Robert Winston and Rebecca Chicot in their study reported that if children have insecurity feeling about their attachment to their primary caregivers which effects the child to form and maintain healthy relationship throughout life, in the present study it states that for children who are being in the intuition for 1-5(64% of respondents) years and 6-10(18%) years have low level of interpersonal relationship as it is said in the above study as they are comparatively younger than others[14]. The present study states that even if the children don't have good friendship in the institution the interpersonal relationship is high among them (2% of the respondents), but on the other hand in the study of Kwame S.Sakyiand et al in their study they concluded that the psychological difficulties in later stage of development is associated with childhood friendship such as those who are having at least one good friend may reduce the psychological difficulties in young adulthood[15].

The present study shows that there is a positive correlation between empathy and interpersonal relationship, also the study of Ruiying Li, Tao Jianget al states that selfless concern about others is the outcome of good interpersonal relationship[16].

Conclusion

The research states that many of the socio demographic variables have influence on both empathy and interpersonal relationship among institutionalised children even though it's very slight. The study also reveals that there is relationship between empathy and interpersonal relationship.

Ethical Clearance: Ethical clearance was obtained before commencing the study.

Assessment of Root Canal Morphology of Mandibular Premolars in North Indian Population Using Different Techniques: An in-Vitro Study

Rajan Dhawan[1], Chitral Chugh[2], Shivani Dhawan[3], Jayata Dhawan[4], Surya Dahiya[5], Jasmeet Kaur[6]

[1]Professor in Department of Conservative Dentistry and Endodontics, [2]Conservative Dentistry and Endodontics, Consultant Endodontist (Chandigarh), [3]Professor in Department of Periodontics, Maharishi Markandeshwar college of Dental Sciences and Research Mullana (Ambala), [4]Senior lecturer in Department of Pedodontics, [5]Reader in Department of Conservative Dentistry and Endodontics, Maharishi Markandeshwar College of Dental Sciences and Research, [6]Senior Lecturer in Department of Conservative Dentistry and Endodontics, Geetanjali Dental Research Institute, Udaipur

Abstract

Introduction: Mandibular premolars have shown higher percentage of root canal failures. The aim of this study was to explore numerous variations in canal morphology seen in mandibular premolars for localization and negotiation of canals as well as their subsequent management in the studied population.

Materials and Method: 400 human mandibular premolars in North Indian population were taken and analyzed to record the canal configuration using Spiral CT and Clearing techniques.

Statistical Analysis: The comparison of different types by Vertucciwas done using Wilcoxon and Mann Whitney test and found to be significant with Spiral CT.

Results: Spiral CT is better in visualizing root canal anatomy as it had shown the presence of Type VI, Type VII and C-shaped canals.

Conclusion: A good understanding of external and internal root anatomy helps to reduce the number of missed roots and root canals during treatment, thus increasing the rate of favorable outcomes following root canal treatment.

Keywords: *Mandibular premolars; Root canal; Clearing technique.*

Introduction

The internal anatomy of root canal exhibit lateral, accessory or diverse canals, fins and isthmuses which harborbacteria, tissue and necrotic debris, obscures cleaning and shaping procedures. Failure of knowledge of these variations in canal configurations leads to incomplete cleaning and shaping, thus leading to failure of root canal treatment.[1]

Mandibular premolars are morphologically similar and generally have single root canal but it is often seen that they are not as simple as it looks on a plain radiograph.[2] **Ghiasi J et al**, stated that variations in canals of these teeth make them the most difficult one out of all other teeth to treat endodontically because of high failure rate and flare ups.[3]

Corresponding Author:
Dr. Shivani Dhawan MDS
Professor in Department of Periodontics, Maharishi Markandeshwar College of Dental Sciences and Research Mullana (Ambala)
Phone No.: 7206310000
e-mail: endorajan@gmail.com

Root canal system of mandibular first premolar is wider buccolingually than mesiodistally and has large buccal horn and rounded small lingual horn.[4]

Mandibular second premolar is almost related to mandibular first premolar apart from that the lingual pulp horn is larger, root canal and roots are frequently more oval than round, buccolingually wider pulp chamber and number of canals canbe 2, 3 or 4.[4]

In vitro method of studying root canal anatomy include direct observation, microscopic observation, macroscopic sectioning, microscopic sectioning, dye filling, decalcification, filling and clearing, radiography, contrasting media (hypaque) and cone beam tomography and Spiral CT(Spiral computed tomography). [5]

Spiral CT acquires a raw projection data with a spiral-sampling focus in a relatively short period, by employing a translation of the subject through the X-ray source, with continuous rotation of the source-detector assembly. Without any additional scanning time. These data can be viewed as conventional transaxial images, multiplanar and three-dimensional reconstructions.[6]

Staining of the root canals followed by tooth clearing is a gold standard for evaluation of root canal morphology as it analyses the root canal anatomy and depicts the 3D view of pulp cavity in relation to the exterior of the tooth.[7, 8,9]

Data on root and canal morphology of mandibular premolars from indigenous Indians is scarce and till date there is no sufficient published data on root canal morphology of North Indian population. Therefore, the aim was to evaluate the canal morphology of mandibular premolars in North Indian population using two different techniques.

Materials and Method

This in-vitro study was conducted in Department of Conservative Dentistry of M.M.C.D.S.R. college Ambala. 400 mandibular premolar teeth from various colleges were collected. Teeth with fracture, metallic restoration, deep caries and incompletely formed apex were excluded. Teeth were cleaned with ultrasonic scaler and stored for 30 minutes in 5.25% NaOCl for debridement of organic debris. Samples were then stored in normal saline till usage.

Spiral CT Evaluation: Two 2"x2" thermocol sheets were taken each holding 200 teeth for evaluation which were arranged in rows of 20 and columns of 10. A 64-slice spiral CT scan (5th generation SIEMENS SOMATO DUO) was used. A section thickness of 0.6mm and a section position of 0.3mm were obtained at 120kVp and 190m A. The software used to view the scanned teeth was SIENETS Sky-DICOM CD Viewer. Canal patterns were observed in the cross section views of Spiral CT. **(Figure 1).**

Clearing Technique: Access cavity preparation was done with air-rotor using endo access bur and canals were negotiated using 8 and 10 K files. The shape of canal orifices was observed with naked eye. The samples were placed in 2.5% sodium hypochlorite for 2 days. After 2 days, teeth were washed in running water for 2hrs and then placed in 5% Nitric acid for decalcification for next 3 days at 37°C.

The Nitric acid was changed every day and samples in container were agitated several times a day. After decalcifications, these samples were washed in running water for 2 hrs and submitted for dehydration in 70% ethyl alcohol solution whole night, followed by 90% solution for one hour and rinsed thrice with 100% ethyl alcohol for consecutive three hours. At the end of this period, no opacity remained in this sample.

The samples were kept in methyl salicylate for 3 days for completion of clearing procedure. After the procedure, the samples were washed and dried. Then Indian ink dye was injected into the root canals with the help of 27-gauge needle. Once the dye was dried, root canal morphology was analyzed to record the canal configuration and photographs were taken. (Figure 2).

Root canal patterns were evaluated using Vertucci's classification.

Type I- A single canal extends from the pulp chamber to the apex.

Type II- Two separate canals leave the pulp chamber and join, short of the apex, to form one canal.

Type III- One canal leaves the pulp chamber and divides into the root; two then merge to exit as one canal.

Type IV- Two separate, distinct canals extend from the pulp chamber to the apex .

Type V- One canal leaves the pulp chamber and divides short of the apex into two separate, distinct canals, with separate apical foramina.

Type VI- Two separate canals leave the pulp chamber, merge in the body of root and redivide short of the apex to exit as two distinct canals.

Type VII- One canal leaves the pulp chamber, divides and then rejoins in the body of the root and finally redivide into two distinct canals short of the apex.

Type VIII- Three separate, distinct canals extend from the pulp chamber to the apex

Statistical Analysis: The data was analyzed by SPSS (21.0 version). Shapiro Wilktest was used to check the normal distribution.

The comparison of types of canals was done using Wilcoxon paired t test and Mann Whitney test. It was found to be significant with Spiral CT. Type VI, type VII and C-shaped canals were shown by Spiral CT and not by Clearing technique. (Graph-1, 2) (Table-1, 2).

Discussion

The mandibular premolars show a lot of variations in the number of roots, canals and pulp cavity configurations. Serman & Hasselgreenin 547 full mouth radiographs of patients, found that 15.7%of patients had at least one first mandibular premolar with either a divided canal or a root, whereas second premolar had an incidence of 7%.[10] Rodig & Hulsmann[11] Shapira & Delivanis[12] observed 2 canaled mandibular premolars, whereas Wong[13] Holtzman[14] Rhodes[15] Macri & Zmener[16] and Sachdeva GS et al[17] observed 4 canaled mandibular second premolar.

In the present study, the canal configuration of samples were classified according to Vertucci, as it is the most accepted method.[18]

Indian ink was used for staining asit is a perfect staining substance that can be easily applied, quickly fixed, durable, inexpensive, contains no potential contaminants, doesn't stain surrounding tissues and look brighter under the microscope.[19]

Spiral CT provides a better resolution as compared with CBCT and allows clinician to observe multiple slices of tooth roots and their canal systems.[20] Mushtaq M et al successfully managed mandibular first molar endodontically with 3 distal canals with help of Spiral CT.[21]

Mandibular second molar fused with a paramolar was endodontically managed with the aid of Spiral CT by depicting the presence of very rare three independent mesial roots and one distal root.[22]

This is the first study where Spiral CT has been used and compared with Clearing technique, so direct comparison with other studies is not possible.

The results of root canal configuration evaluated by Spiral CT showed that Type I canal pattern was found in 75% and 80% by clearing technique. **Banga KSet al[18]** found 70% of Type I canal configuration in mandibular premolars, **Jain A and Bahuguna R[23]** observed 67.39%, **Singh and Pawar[24]** found 80%, **Vertucci F J et al[25]** reported the same pattern in 70% of mandibular first

premolars, **Sandhya R et al[6]** in 72%, while **ZillichR et al[26]** reported an incidence ranging from 67.2% to86.3%. Type I is the most prevalent canal pattern becausethis canal configuration is the commonest and easy to visualize through naked eye.

The Type II canal patternevaluated by Spiral CT was 10% and by Clearing technique it was seen in 7% of teeth. It was found higher in **Banga KSet al[18]** that was 11.36%. **Jain A and Bahuguna R[23]** observed in 7.97% of teeth whereas **Sandhya R et al[6]** reported 6% and **Rahimi S et al[4]** 5.6%.Type II canal was better visualized in Spiral CT through axial sections.

Type III canal patternwas seen in 4% of teeth both by Spiral CTand by Clearing technique, which is in accord with the findings of **Parekh V et al[9]** who found 5% of Type III canal configuration. **Al-Qudah AA and Awawdeh LA**[27] who reported the same pattern with 1.4% in mandibular first premolars and 1% in second premolars. **Jain A and Bahuguna R[23]** observed Type III canal pattern in 3.62% of teeth which was almostsimilar to 4% in findings of **Vertucci F J et al[25]**

Due to better dye penetration and easily visualization results were found to be same by both method.

Type IV canal pattern evaluated by Spiral CT was seen in 2% and by Clearing it was found in 3% of mandibular premolars which is in accord with **Vertucci F J et al[25],** who observed this configuration in 1.5%. **Jain A and Bahuguna R[23]** observed Type IV canal pattern in 2.89% of teeth, **Sandhya R et al[6]** in 10% and **Rahimi S et al[4]** in 22%.

This can be due to presence of two roots and of two canals in mandibular first premolars, which can be easily visualized by naked eye.

Type V canal pattern evaluated by Spiral CT was seen in 4% and by Clearing it was observed in 6% of teeth. 8% was the pattern observed by **Sandhya R et al[6]** in mandibular first premolars. **Caliskan M K et al[28]** observed same pattern in 9.32% of cases.**Jain A and Bahuguna R[23]** observed Type V canal pattern in 17.39% of teeth while **Vertucci F J et al[25]** found this system in 24% of teeth.

Type VI pattern evaluated by Spiral CT was seen in 1.8% and by clearing it was seen in 0% of teeth which was in accord with findings of **Jain A and Bahuguna R[23]** i.e. 0.72%.

Type VII pattern evaluated by Spiral CT was seen in 1.2% of teeth while 0% was seen by Clearing technique. Type VIII canal pattern was not observed by any technique. This finding was in accord with the studies done by **Rahimi S et al[4], Sandhya R et al.[6]**

Vertucci F.J et al[25] inferred that it is difficult to locate type VI VII and VIII canal pattern through clearing technique.

The differences in the incidence of canal systems in the present study and others could be attributed to racial difference, since this study was carried out on a North Indian population, **Rahimi S et al[4]** on Iranian population, **Sandhya R et al[6]** on South Indian population, **Banga KSet al[18]** on Marathi population, **Jain A and Bahuguna R[23]** on Gujarati population.

Out of 400 mandibular premolars, 2% teeth showed presence of C-shaped canals at coronal third level with help of Spiral CT that was not visualized through Clearing technique.**Lu T Yet al[29]** reported 18% incidence of C shaped canal in Chinese population. **Baisden M K et al[1]** reported incidence of C shaped canal in 14% of mandibular first premolars.C shaped canal configurations can be difficult torecognize, prepare and obturate. It occurs more often in mandibular 2nd molars.

Similar studies with large sample size and latest radiographic techniques like CBCT are needed, that would help todevelop a standardized baseline point for root canal anatomy, making endodontic therapy to be more predictive and effective.

Abstract

Aim: The aim of the present study was to assess knowledge, attitude and practice towards passive smoking among south Indian population.

Method: A cross sectional study had been conducted using a pre-validated questionnaire through google forms. The questionnaire was divided separately according to whether they were a smoker or not. The questionnaires were collected and the data were analyzed.

Result: There were total of 651 individuals of ages 15-60 years. Out of the whole analysis, there were 77% of people who knew what passive smoking was out of 76 smokers 7 were females and 69 males. Many did know the harmful effects of smoking among both smokers and non-smokers.

Conclusion: Smoking is always harmful and hence, this survey can be used to create more knowledge on passive smoking so as to make people more careful and ensure that others around them are also not affected. It should be made mandatory to create more awareness on smoking and passive smoking to have a better future generation.

Keywords: *Passive smoking, Second hand Smoke, Tobacco.*

Introduction

Smoking is a deadly habit that not only risks the life of the people addicted to it but also the people around them. WHO Report on Global Tobacco Epidemic 2011 states that 6 million people are killed annually along with a high amount of economic plunge.[1]

There is a misbelief that passive smoking is not as harmful as active smoking which is contradicted by this statement that there are a very high amount of people, including children, who die due to second hand smoking every year.[2-4] Second Hand Smoking (SHS) has been known to cause potential health disorders such as cardiovascular problems, chronic obstructive pulmonary disease and malignancies.[5-8] Middle ear disease, sudden infant death syndrome (SIDS), lower respiratory ailments are some of the dangers faced by children exposed to second hand smoking.[9,10] Some studies show that, there is a directly proportional relationship between low birth weight in infants and mothers exposed to second hand smoking.[11]

Various anti-smoking measures have been taken by the government of India to bring down the usage of tobacco products. The Global Adult Tobacco Survey 2 [GATS 2] uncovered that there are an equal number of men and women affected by passive smoking with a 52.3% of adults among them. GATS-2 has also provided information that there is relative decrease in the amount of people who undergo passive smoking.[12]

Although number of studies focus on the perception and attitudes of smokers on smoking, not many studies focus on the perception of non-smokers. This study is aimed to assess the perceptions and attitudes of smoking and also non-smoking adults towards second hand smoking.

Method

A cross sectional study was conducted from September 2017 to January 2018 on google forms with an aim to assess awareness and attitudes towards passive smoking conducted. A pre-validated questionnaire was used which consisted 10 questions to assess the knowledge about tobacco and its usage. The questionnaire also consisted of separate set of questions to assess the attitude of smokers and non-smokers.

Questionnaire was forwarded to the participants, on Google docs. The filled questionnaires were returned and collected data was analysed using descriptive statistics and chi square test was used to check the association of perception of passive smoking between smokers and non-smokers.

Results

The result of this study includes 651 adults of age between 15 -60 years of data were included in this analysis. The responders for smokers in which male are 69 (90.8%) and female are (9.2%). The responders for non- smokers in which male are 329(57.2%) and female are (42.8%)

Perception of Non-Smokers: Most of the non-smokers (75.8%) minded if someone smokes around them and some of about 24.1% don't mind if they smoke around them. About 85% of non-smoker walk away when someone smokes around them and people of about 15% won't walk away.

Majority of people of about 76% thought that they have right to ask people not to smoke near them and about 34% of people have thought that they have no right to ask about 56% of people asked a smoker to stop smoking in their presence. Nearly 72% of people feel a smoker should ask for their permission before they smoke around them. About 62.4% of people usually when they are in car or public transport ask people around them not to smoke and about 57.5% of people usually talk to smokers about their health risk while some of about 42.5% won't talk about it.

Perception of Smokers: Majority of people of about 60.5% won't light up a cigarette when non-smokers are around and some of about 39.5% will light up. Most of the smokers of about 72.3% attempted to quit the smoking in the past. About 84.2% of smokers plan to quit smoking later. Most of the people among smokers (92%) knew that smoking is dangerous to their health. Some people of about 34.2% had withdrawn from the smoking by the pictorial health warnings on the cigarette packs.

Table 1: Gender distribution between smokers and non-smokers

	Gender	Frequency	Percentage
Smoker	Male	69	90.8%
	Female	7	9.2%
	Total	**76**	**100%**
Non smoker	Male	329	57.2%
	Female	246	42.8%
	Total	**575**	**100%**

The percentage of people who knows about passive smoking are 77.1% and who doesn't know are 22.9% Also the percentage of people who smoke are 11.7% and who doesn't smoke are 88.3%.

The percentage of people who walk away when someone smokes around them are 75.8% and who doesn't are 24.1% and also the percentage of people who asked a smoker to stop smoking in their presence are 56% and who doesn't are 44%

The percentage of people won't light up cigarette when non-smokers are around is 60.5% and who will light up are 39.5% and also the percentage of people are planning to quit smoking later is 84.2% and who won't are 15.7%

The p-values were calculated in order to identify the significance of responses related to whether children have respiratory problems due to passive smoking and whether smoke from hookah is harmful or not proved to be significant whereas, other responses were not significant.

Discussion

Passive smoke is the smoke that fills the air in many places when a person lights a cigarette or beedi or any other smoking tobacco product and this can be inhaled by anyone.[1] The ill effects of passive smoking were

not known to the people for a very long time and were thought to have no effect on the health.[2] But, there were much harm that can happen due to it. Passive smoking can cause irritation and damage of the respiratory epithelium and had an effect similar to normal smoking.[3,4] There were not only ill effects on adults but children too had multiple complications due to passive smoking which would eventually cause a change in their lifestyle.[5] Cardiovascular ill effects are also on par with respiratory effects where endothelial damage is primary effect of toxins in the smoke to the body. These later can become complicated leading to acute coronary syndrome and other cardiovascular diseases.[6] Women during their pregnancy, on inhaling the smoke can cause damage not only to their bodies but also the baby developing in them. There can be alterations that can occur in their psychomotor development later in their life.[11] Various measures had been taken by the Indian government to cut down usage of tobacco products which relatively cuts down passive smoking.[12]

A survey was conducted to assess the perception and attitude on the ill effects of passive smoking among individuals residing in southern India. The survey was a cross sectional study and consisted of a questionnaire that questioned individuals first whether they know what is passive smoking and its ill effects and then divided them based on whether they are a smoker or non smoker. Further questionnaire was prepared to separately question smokers and non smokers. The sampling was a snowball sampling and individuals who were interested could participate as the questionnaire was forwarded to them online. In the conducted survey there were 88.3% non smokers and 11.3% smokers with a sample size of 651.

Among the individuals 77.1% were aware of what is passive smoking and was also reported in the global youth tobacco survey that 61% of school students were taught about passive smoking.

There was a higher population of males (90.8%) who have been addicted to smoking compared to the population of females (9.2%) and such an outnumbering result of males over females were also reported in study of prevalence of tobacco use in Chennai city (Kolappan et.al)[13] where the males had a higher count of 39.6% and females a much lower count of only 5%. Another similar study on prevalence and prediction of smoking and chewing tobacco (Rani et.al)[14] was showing that the incidence of smoking among males (47%) were higher than females (14%).

There was a total of 72.3% people who had attempted to quit smoking when compared to a similar study conducted on awareness, attitude and use of tobacco among medical students in Chennai (Ramkumar et.al)[15] where it was 26.9% among that population.

Advantages to our survey were that many people were more aware about smoking and passive smoking. The other advantage in the survey was that the data collection was much faster as it was circulated via internet and the reach was much further among the southern regions. The likelihood of a person after conducting such a survey on awareness can help the person to be more educated on such an issue and improve their lifestyle and the ones surrounding them.

There were few limitations to our study, the first being the method of circulation itself, where the questionnaire was provided to everyone through online circulation and there could have been chances of mix and match of personal views. Secondly, the only population that was included were the southern people of India which cannot give an idea or perception on passive smoking about the people residing in the other parts of India.

Assess Knowledge and Attitude Regarding Child Abuse among Mothers in Selected Areas of Gurugram with a View to Develop Pamphlet

Poonam Ahlawat[1], Shweta Handa[2], Shivani Sharma[3], Komal Upreti[3], Varsha[3]

[1]Lecturer, [2]Assistant Professor, [3]B.Sc. Nursing students, Faculty of Nursing, SGT University

Abstract

Childhood is the primary stage and the golden period of life. It is said that God resides in a child's heart. Abusing a child is like insulting the God you preach. Government of India study on child abuse (UNICEF) the findings of the Study on Child Abuse clearly indicate that a very large number of children in India are not even safe in their homes. It is here, in the home, that we must start tackling the problem of child abuse. Interventions are needed to bring about change in the ways family members behave towards children in the home. The latest data from India's NCBR recorded a 12% rise in number of rape related cases up from 34,651 cases in 2015 to 38,947 in 2016. Haryana, a state known to be unsafe for women and children according to NCRB report a total of 224 minor rape cases in 2015 and in 2016 the number had risen shockingly to 532. The number and rate of maltreated children continued to decline until 2012, but both began to rise in 2016. Guru gram 3,768 sexual assault cases against girls were recorded between august 2014 and September 2018. Present study aims to assess knowledge and attitude regarding child abuse among Mothers in selected areas of Gurugram.

Keywords: *Child, Abuse, Knowledge, Attitude.*

Introduction

Biologically, a Child is a human between the stage of birth and puberty[1]. A child is a tender human being which needs support in all forms for its all round development[2]. Child abuse is a universal problem with grave lifelong outcomes. According to WHO "child abuse or maltreatment constitutes all forms of physical and/or emotional ill-treatment, sexual abuse, neglect or negligent treatment or commercial or other exploitation resulting in actual or potential harm to the child's health, survival, development or dignity in context of a relationship of responsibility, trust or power".There are four major categories of child abuse: physical abuse, neglect, sexual abuse, psychological/emotional abuse.[3]

According to a report one girl in every 5 and one boy in every 10 faces sexually abuse globally[4]. A total of 7,112 cases of child rape were reported during 2011 as equated to 5,484 in 2010 depicting a growth by 29.7%. Studies propose that over 7,200 children, including infants, are raped every year and it is believed that several cases go unreported. Every 2nd child is being exposed to one or the other form of sexual abuse and every 5th child faces critical forms of it[5]. Looking specifically at the incidence of child sexual abuse against children, percentage increases in number of cases in 2016.

The latest data from India's NCBR recorded a 12% rise in number of rape related cases up from 34,651 cases in 2015 to 38,947 in 2016 [6]. Haryana, a state known to be unsafe for women and children according to NCRB report a total of 224 minor rape cases in 2015 and in 2016 the number had risen shockingly to 532. The number and rate of maltreated children continued to decline until 2012, but both began to rise in 2016. Guru gram 3,768 sexual assault cases against girls were recorded between august 2014 and September 2018[7].

Statement of Problem: To assess knowledge and attitude regarding child abuse among Mothers in selected areas of Gurugram with a view to develop pamphlet

Objectives:

1. To assess the level of knowledge and level of attitude regarding child abuse among mothers.

2. To develop and validate information booklet on child abuse.
3. To find out the association of knowledge and attitude with selected demographic variables.

Assumptions: Mothers have some knowledge and have some positive attitude towards child abuse.

There is a significance association between socio demographic variables and awareness of child abuse.

Research Approach: This research approach used for this study is non-experimental research approach. Mothers knowledge and attitude towards child abuse was assessed by structured questionnaires.

Research setting: The study was conducted the selected areas around the Gurugram.

Research design: A descriptive design was used.

Sampling technique: Convenient sampling technique was used to select a sample.

Population: The population included who are all having children.

Sample size: A sample of 100 mothers who met the inclusion criteria were selected.

Ethical Considerations: Approval from the research and ethical committee of SGT University, faculty of nursing was taken to conduct the research to assess knowledge and attitude regarding child abuse among mothers.

Description of the Tool:

Section I: The first section of the tool consisted of 5 items of selected demographic variables like age, education, religion, occupation, no of child.

Section II: It consisted of 21 multiple choice questions about awareness of child abuse.

Date collection procedure

For collecting the date, the following steps were taken, informed consent from the participants. The objectives of the study were explained to each subject and a structured questionnaire was used to collect the information via interview. The confidentially was assured.

The tool consists of three sections:

Section A: It consist of 10 questions on selected socio-demographic variables of the mothers

Section B: This section consists of 26 question regarding knowledge of mothers.

Section C: This section consists of attitude scale to assess attitude regarding child abuse. It consists of 26 items. 5 point likert attitude scale was used..

Findings: Table 1 The data collected were analyzed based on the objectives of the study. Frequency and percentage distribution of knowledge score.

Table 1: Distribution of knowledge score regarding child abuse among mothers N=100

25.	Which of following actions can help to stop child abuse?	75	75
26.	What is the function of child helpline?	95	95

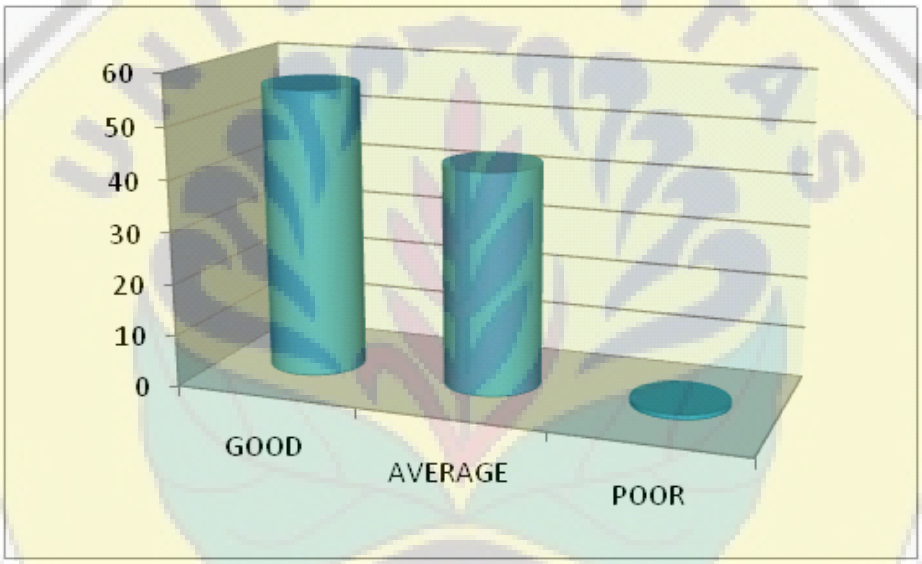

Figure I: Knowledge score of mothers regarding child abuse

Figure (I) revealed that (56%) of mothers had good knowledge regarding child abuse, (43%) had average knowledge and only (1%) of mother had poor knowledge regarding child abuse. The next objective is to assess the attitude regarding child abuse (pie chart 1).

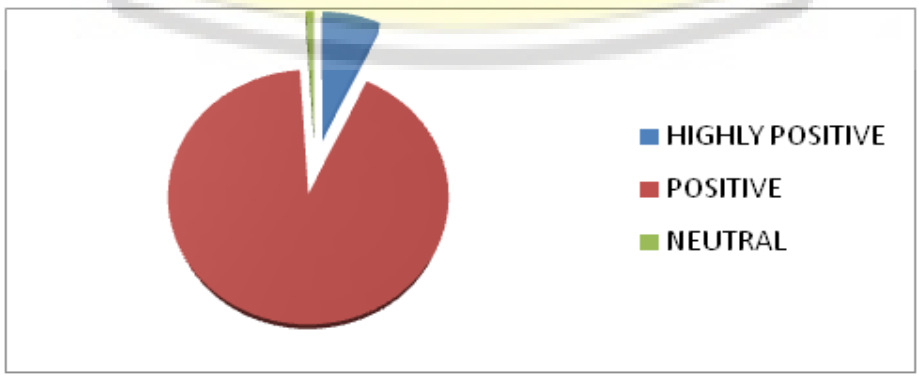

Figure II: Attitude Score od mothers regarding child abuse

Pie chart i.e. figure (II) depict that (92%) of mothers had positive attitude, (7%) had highly positive attitude and (1%) had neutral attitude towards the child abuse.

Third objective of the study was to find the association of Knowledge and attitude regarding child abuse and it was found that age of the mother was significantly associated.

Discussion

Children are one of the greatest gifts to humanity and their abuse is one of the cruelest crimes imaginable. It is a violation of their trust and an ugly breach of our promise to protect the innocent. Reliable estimates are hard to come by since this is a secretive form of abuse, often causing victims to suffer in dark and claustrophobic silence. We urgently need legislation that specifically addresses child abuse with its all form. The necessity for such a law is underlined in government data which shows that more than half of India's children have been subjected to such abuses. Regarding Child abuse, two institutions play a very important role in a Childs life: there is protection and there is prosecution. Protection is the job of the parent. Prosecution is the job of the state. Different studies and their reports indicate that there is a traditional conservative family and community structure that does not talk about this topic. This silence encourages the abuser so that he is safe to sexually abuse. So, there is always a need to discuss with the family members regarding child abuse. With no information being available about child abuse, many children are growing up not knowing their rights have been violated.

Conclusion

Child abuse is one of the dark realities that routinely inflict our daily lives but in majority of cases it goes unnoticed and unreported as well. Merely enacting legislation will not be enough unless it should be followed by strict enforcement of the law with well defined accountability. Parents, family members, teachers and others in the community individuals play a vital role to protect children from sexual exploitation and abuse. As we all know that children are the country's greatest human resource and directly measure for country's social progress. So, sensitizing parents regarding child abuse and having a positive attitude regarding available resources to prevent child abuse. It is our duty that Child Abuse should be combated as early as possible. This will help India shine bright and develop in a crime free way, as children are the leaders of tomorrow.

Fixing the Removable: A Case Report

Prabal Sharma[1], Bhumika Sharma[1], Sandeep Garg[2], Harpreet Kaur[3]

[1]Senior Lecturer, [2]Professor and Head, [3]PG Student, Department of Prosthodontics Including Crown & Bridge, MM College of Dental Sciences & Research

Abstract

Various treatment options can be planned for a completely edentulous patient including implant fixed and removable prosthesis. But, the trident factors: mastication, phonation and esthetics should be given prime consideration while doing any dental procedure so as to achieve good prognosis. Though, prognosis depends majorly on the underlying residual bone as well as the mucosa,which helps the prosthodontist to determine the choice of a suitable prosthetic treatment option for a particular patient. Various studies over the past decade have shown the advantages of a mandibular implant over denture rather than conventional denture - as the first treatment option for a completely edentulous mandible. An implant supported hybrid prosthesis is an acrylic resin complete fixed dental prosthesis and supported by implants might be a solution in extreme cases that the need of the restoration for esthetics, function, lip support and speech.

Therefore, this clinical report aims to present the esthetic and functional prosthetic rehabilitation of a mandibular ridge with implant supported fixed prosthesis.

Keywords: *Edentulous Mandible, Implants, Over Dentures, Retention, Prosthesis, Hybrid Denture.*

Introduction

Edentulism is a form of physical impairment, as the loss of all teeth causes a disability for those who wear conventional dentures (CD), they may have difficulty in performing two essential tasks;eating and speaking.[1]Thereby, it can be said that a tooth loss is a major life event for patient's confidence and functionality.[2] Most of the complete denture wearers in spite of proper denture fabrication and lab handling are not satisfied with their mandibular dentures. Redford et al showed that over 50% of mandibular complete dentures have problems with stability and retention.[3] So, to get a satisfactory stability and improved retention mandibular complete implant- supported overdentures andfixed hybrid prostheses can be planned.

While selecting between a fixed or a removable restoration all the following points should be considered prior to reach the final treatment plan: the available bone quantity and quality, the number, location and implant distribution, the available inter-arch distance and maxillary-mandibular relationship, the nature of the opposing occlusion, the expenses as well as the time frame required to assemble and maintain the prosthesis.[4]

The fixed-implant supported prosthesis can either be screw-retained orcemented over the implant abutments. The traditional screw-retained metal-resin prosthesis (hybrid denture prosthesis) is one of the most popular choices for prosthetic therapy in edentulous mandibles. The advantages of this prosthesis are its long track record of success and its retrievability.[4] Apart from the above mentioned advantages, hybrid prostheses can also replace soft tissue defects. However, lack of passive fit in the framework and distortion (which is possible to occur anytime during the fabrication) are major obstacles in the process of prosthesis fabrication.[5]

A Hybrid denture is an implant-supported fixed denture where "Hybrid" refers to the fact that fixed denture is fabricated with both metal and plastic, making

it a hybrid of the two. Therefore, it is a denture in the sense that it is fabricated same as a complete denture or partial denture, but it is supported by a metal frame that is screwed into the implants. Also known as "Fixed Detachable denture"

This article presents rehabilitation of a complete edentulous mandibular arch with an implant retained hybrid denture.

Material and Method:

Case Report : Mandibular Implant-Retained Hybrid Denture

A 46 year-old female patient reported to the Department of Prosthodontics, MM College of Dental Sciences and Research, Mullana with a chief complaint of loose lower complete denture prosthesis. The patient was unable to speak and eat properly as the lower denture was loose. History revealed that the patient was a complete denture wearer from last three years and had underwent multiple tooth extractions following dental caries and endodontic treatment. Clinical examination revealed that the patient had completely edentulous upper and lower arches [Figure 1].The maxillary arch was U-shaped, smooth with no irregularities, no bony spicules, the mandibular ridge was found to be adequate in height but was irregular. Extraoral examination revealed that there was no facial asymmetry or mandibular deviations upon opening and closing. Mouth opening was 42 mm with sufficient inter arch space. Radiographic examination of the patient showed that patient had dense compact bone in the mandibular anterior region without any pathology. As the patient expressed unwillingness to be rehabilitated with any removable treatment option for mandibular ridge and desired for esthetic and functional rehabilitation. Therefore, conventional complete denture was planned for maxillary arch and screw retained implant-tissue supported hybrid prosthesis for the mandibular arch.

Clinical Procedure:

Stage I: Implant Surgery: A full thickness mucoperiosteal flap was raised in the mandibular arch and 5 implants (Tapered self-thread, ADIN Dental Implant System Ltd, Israel) were placed in 2nd premolars and canines in both quadrants and one implant in the midline [Figure 2]. Patient was recalled after 1 week for suture removal.

Stage II : Implant Surgery: After a waiting period of 3 months, Stage II surgery was performed under local anesthesia in which cover screws were exposed and five healing abutments were placed [Figure 3]. Healing abutments were fastened to the implants to allow undisturbed soft tissue healing.

Prosthetic Phase: After 1 week, when the soft tissue has grown around healing abutments, the healing abutments were removed and impression copings were connected to the implants for the indirect impression technique [Figure 4].The tray was then loaded with putty and light body impression material (Zhermack Zetaplus Putty Impression Material)was injected around the impression copings and impression was made.Then, the tray was removed. The impression copings were unscrewed from the implants with the Hex Tool and along with the implant analogue were then incorporated into the impression [Figure 5].

The implant replicas were held in place to prevent rotation of the impression copings. A thick layer of Esthetic Mask (Detax Esthetic Mask Automix) was injected around the implant analogues and impression copings till the junction of both to simulate the soft tissue around them. The healing abutments were attached to the implants and patient was sent.

In the laboratory, impression was poured and the master cast was recovered with the Implant replicas embedded in the cast [Figure 6]. Record bases and occlusion rims were fabricated. [Figure 7]. Patient was recalled for recording of maxillo mandibular relations and after obtaining the record master casts were then mounted on a semi adjustable articulator. A verification jig was fabricated on the master cast along with the castable abutments with the help of Pattern Resin (GC Pattern Resin) which verifies and ensures that the final screw-retained framework has the optimal passive seat. After taking the jig trial in mouth,[Figure 8 a & b] the framework was waxed on the master cast and was casted later. The casted metal framework was checked in mouth and proper seating was confirmed [Figure 9].Then, metal framework was waxed up and trial was done [Figure 10]. The investing, flasking and processing procedures for the hybrid prosthesis were then completed. The prosthesis was finished and polished. The maxillary complete denture was flasked and processed by use of the maxillary master cast as any conventional complete denture. Maxillary conventional denture and mandibular hybrid denture were then delivered to the patient after

adjusments. The hybrid prosthesis was screw retained and composite resin was used to cover the screw access holes[Figure 11 a & b].Patient was advised to follow-up for any adjustments if needed.

Maintenance Phase: Patient's oral hygiene was reviewed after one month and rest were scheduled after every six months for maintenance.

Discussion

Major advantage of a fixed detachable (hybrid) denture is that it is always held securely in place and can only be removed by the dentist. The rehabilitation with hybrid dentures has been observed to achieve greater masticatory function and psychological satisfaction than with conventional complete dentures.[6] The hybrid denture is made to leave a space between the denture and the bone to enable clean easily underneath the denture without removing. So, it is recommended to visit the dentist twice a year, to assess the condition of peri-implant tissue and bone to avoid any unforeseen complications and professional cleaning is done.

Although, occlusal forces tends to increase considerably following the placement of an implant-supported prosthesis.[7]It should be kept in mind that passive fit is the prerequisite for survival of implants in bone[8] and not achieving it leads to mechanical and biological failures.[9] Jacobs et al, stated that complete edentulism can affect speech quality due to the absence of the periodontal ligaments which is responsible for speech sensation.[10] Removable overdentures are similar to the pattern of the complete dentures, whereas the bases of fixed prostheses are generally narrower, which could explain the cause of speech adaptation problems encountered by patients.[11] Various studies showed fixed prosthesis are more successful in the mandible regarding stability, ability to chew, aesthetics and ability to speak. Thereby, making implant retained fixed hybrid denture as the treatment of choice over a removable implant overdenture.

No. of implants used to support a full denture is a debatable issue. The hybrid prosthesis is ideally placed on the largest possible number of implants, but on a minimum of 4 implants.[12] In this particular case five implants were planned ie. in position A, B, C, D and E. As framework fabrication requires many steps, the cause of distortion in implant frameworks may be multifactorial.[13] The factors may include implant alignment, impression technique and materials, framework fabrication process, design configuration and clinician and technician experience.[13,14] Also, dimensional changes occur related to the chemical reactions of impression materials, dental stones and investment materials.

A hybrid restoration is indicated when the intra-arch distance is more than required for implant supported fixed prosthesis.[15] In the present case, the distance present was suitable for placement of hybrid prosthesis.

Zarb and Jansson[16] stated that fixed detachable hybrid prostheses could be designed using one of the following two method: (a) a metal framework comprises the bulk of the prosthesis and artificial teeth and a small denture base are the only non-metallic components, (b) the implant-fixed prosthesis consists mostly of an acrylic resin denture bases (wrap-around design) and artificial teeth, with a small metal framework. In the described case, the second design method was used for the superstructure.

Advantages of hybrid denture:

1. Hybrid denture restores new teeth and gums to give a proper esthetic and facial support.
2. Unlike conventional dentures, hybrid dentures are stable
3. Implant hybrid dentures cannot be removed by patients but can be removed by the dentist for maintenance if required.
4. Are much less expensive than crowns on individual implants.

Disadvantages:

1. Need to clean under the denture flanges and denture teeth may require maintenance overtime.
2. Passive fit of the metal substructure may require sectioning and soldering after initial fabrication.
3. Access holes must be present to allow for screw tightening or retrieval of the prosthesis which may compromise esthetics and occlusion.

Conclusion

Every patient has unique treatment needs. Proper diagnosis and treatment plan are important but cannot be all-inclusive. A comprehensive examination, including a thorough medical & dental history, clinical examination, dental radiographs, diagnostic impressions are some

important steps to a successful oral rehabilitation. It can be concluded that the rehabilitation of an edentulous mandible with the implant supported hybrid denture provides more satisfaction with the prosthesis, improved masticatory ability and nutrition, along with improvements in psycho-social aspects of life. Moreover, this clinical method is more conservative, feasible and reliable that does not require advanced surgery. Retention & stability were found to be good upto 12 months of review.

A Prospective Observational Study Regarding Awareness of Prescription Errors among Resident Doctors in SKNMC & GH, Pune

Prachi Jain[1], Vasundhara Bhople[2], Uma Bhosale[3]

[1]JR III, [2]Assistant Professor, [3]Professor & Head of Dept. Pharmacology, Dept. of Pharmacology SKNMC & GH Pune

Abstract

Objective: To study regarding awareness of prescription errors among resident doctors in SKNMC & GH, Pune.

Method: A prospective observational study- Questionnaire based. This study includes residents from all the clinical fields. It was conducted in Department of Pharmacology after due clearance from Institutional Ethics Committee & after taking written informed consent from resident doctors.

Results: Few residents had knowledge about recommended prescription format by Maharashtra Medical Council (MMC), number of doctors' names that can be written on a single prescription pad MCI recognized abbreviations, parts of prescription and believed that drugs could be prescribed by their brand names prior to intervention. Their knowledge improved post- sensitisation. Sensitisation made them aware about the availability of online prescription, its medicolegal use and its importance to maintain patient's and doctor's safety.

Conclusion: The study has highlighted the need to have sensitization programme for residents regarding prescription writing along with knowledge about medicolegal consequences which will further reduce the overall incidence of prescription error and promote patient's and doctor's safety.

Keywords: *Prescription error, Questionnaire, Maharashtra Medical Council (MMC).*

Introduction

Medication errors are commonly encountered in hospitals and general practice.(1)

The National Coordinating Council for Medication Error Reporting & Prevention (NCC MERP) definition of medication error is "Any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of health care professional or consumer".(2,3,4,5,6) Prescription error is an important component of medication error which is the second most common cause of patient safety incidents.(7,8)

Prescription error can be defined as an error that occurs as a result of a prescribing decision or prescription writing process which leads to unintentional significant reduction in the probability of treatment being effective and in time or increase in the risk of harm when compared with generally accepted practice"(9) There are huge variations in the types of events included under prescription error. For example, Betz and Levy include "prescribing a medication without sufficient education

Corresponding Author:
Dr. Vasundhara Bhople
C/O Dr. Avinash Londhe, Flat NO B 401, Sun Gloria, Near Matoshree Furniture, Dattanagar-Narhe Road, Pune 46
Mobile No.: 9527053739
e-mail: drvasu_18@yahoo.com

of the patient on its proper uses and effects" under prescription error.[10]

Errors in prescription writing can be further categorized as Errors of omission (when rate or dose, concentration, dosage form, duration, frequency, route omitted and when prescriber signature missing), abbreviated and non standard drug names, error prone abbreviations, symbols and dose designations, prescribing one tablet of drug when available in more than one strength of tablet, writing milligram when microgram was intended. It could arise as a consequence of insufficient training, lack of awareness of errors, polypharmacy, lack of standardization and particular care environments.[7,12,13]

Using human error theory, above errors can be broadly classified into individual factors and system factors [14] Prescribing errors are reported to affect 1-100% of all patients admitted to hospital [15] Most of the actual prescribing in hospital is done by junior doctors, although they may not be wholly responsible for all prescribing decisions. Despite comprehensive understanding of the subject, a junior doctor might face challenge initially to write prescription correctly. There have been previous studies which stated high incidence of prescription error which were mainly by residents and most of these errors were preventable. Dean et al reported that 57 % were lapses; whereas 43% of errors were mistakes or violations. This suggests that errors due to insufficient knowledge are important and educational interventions at undergraduate and post-graduate levels could address this dreaded issue [12] Sensitization programme regarding prescription errors for newly joined residents could also help, as residents keep on changing regularly. Correction of prescription error can improve the quality of prescription and also help in patient care [16] There is lack of awareness about prescription errors; present study is therefore planned to assess and improve the knowledge, awareness, attitude and perception about prescription errors amongst junior doctors which is based upon validated questionnaire to be administered before and after a planned teaching session on prescription errors. This will ultimately help to reduce prescription errors and improve prescribing.

Method

A prospective, questionnaire based, interventional study was conducted in Department of Pharmacology at Smt. Kashibai Navale Medical College & General Hospital, Pune. This study included residents from all clinical departments.

Inclusion Criteria:

All the resident doctors including junior resident of all cadres and senior residents.

Exclusion criteria:

Resident doctors who did not give consent for the study.

Incomplete questionnaires were excluded.

Study Design: A pre-validated questionnaire was designed to assess the knowledge of resident doctors. The questionnaire was viewed by faculty of pharmacology for precision and required modifications were done. This validated questionnaire includes questions on three main categories- details of prescription, measures to prevent prescription error and legal importance of prescription. Each subhead had 5 questions of which 3 were closed ended and 2 were open-ended.

The following validation criteria were used:

1. Time requirement for completion of questionnaire (10-15 min)
2. Appropriateness of questionnaire for collecting data
3. Repetition or inappropriate questions
4. Logical order of questions
5. Clear concise and ambiguous questions
6. Easy and meaningful instructions

After getting protocol approved by Institutional Ethics Committee (SKNMC No/Ethics/App/2018/415), the list of residents in clinical departments at SKNMC & GH was obtained. After getting the list, a total number of 100 residents were administered pre-validated questionnaire containing 15 questions and they were asked to fill up the questionnaire. The filled questionnaires were collected after 15 min of distribution. It was followed by an educational intervention where they were made aware of prescription related problems and method to fill the prescription as per recognized prescription format. After a week, same pre-validated questionnaire containing 15 questions was administered and they were asked to fill up the questionnaire. Pre and post educational intervention results were compared using descriptive statistics. Statistics was represented

by percentage through bar diagram which deduced percentage differences among variables pre-intervention and post-intervention.

Results

Out of the total 100 residents, 63 were females and 37 were males. Mean age of residents was 25.97 years.

Knowledge about Prescription Writing: 53% of residents had knowledge about recommended prescription format by Maharashtra Medical Council (MMC) prior to intervention and 47% of residents did not have any idea about the MMC recommended prescription format. Post-intervention, 99% of residents had knowledge about recommended prescription format by MMC.

27% of residents believed that drugs could be prescribed by their brand names,59% of residents differed in their opinion while 14% of residents responded that they did not know about it prior to intervention. Post-intervention, 15% of residents opined that drugs could be prescribed by their brand names, while according to 85% of residents, drugs could not be prescribed by their brand names.

When residents were asked about number of doctors' names that can be written on a single prescription pad, 53% of residents answered one, 30% of residents answered two, 17% of residents answered as many as you want prior to intervention. Post-intervention, When residents were asked about number of doctors' names that can be written on a single prescription pad, significant improvement was observed as 90% of residents answered correctly eg. one, only 7% of residents answered two while 3% of residents answered as many as you want.

55% of residents were aware of MCI recognized abbreviations (OD, BID, TID, QID, HS, SOS) and 45% of residents were not aware prior to intervention. Post-intervention, 75% of residents were found to be aware of MCI recognized abbreviations (OD, BID, TID, QID, HS, SOS).

When data on knowledge about parts of prescription (superscription, inscription, subscription and transcription) was analysed, 36% of residents were found to have knowledge about parts of prescription while 64% of residents had no knowledge regarding this prior to intervention. Post-intervention, 82% of residents had knowledge about parts of prescription (superscription, inscription, subscription and transcription). (See Figure 1).

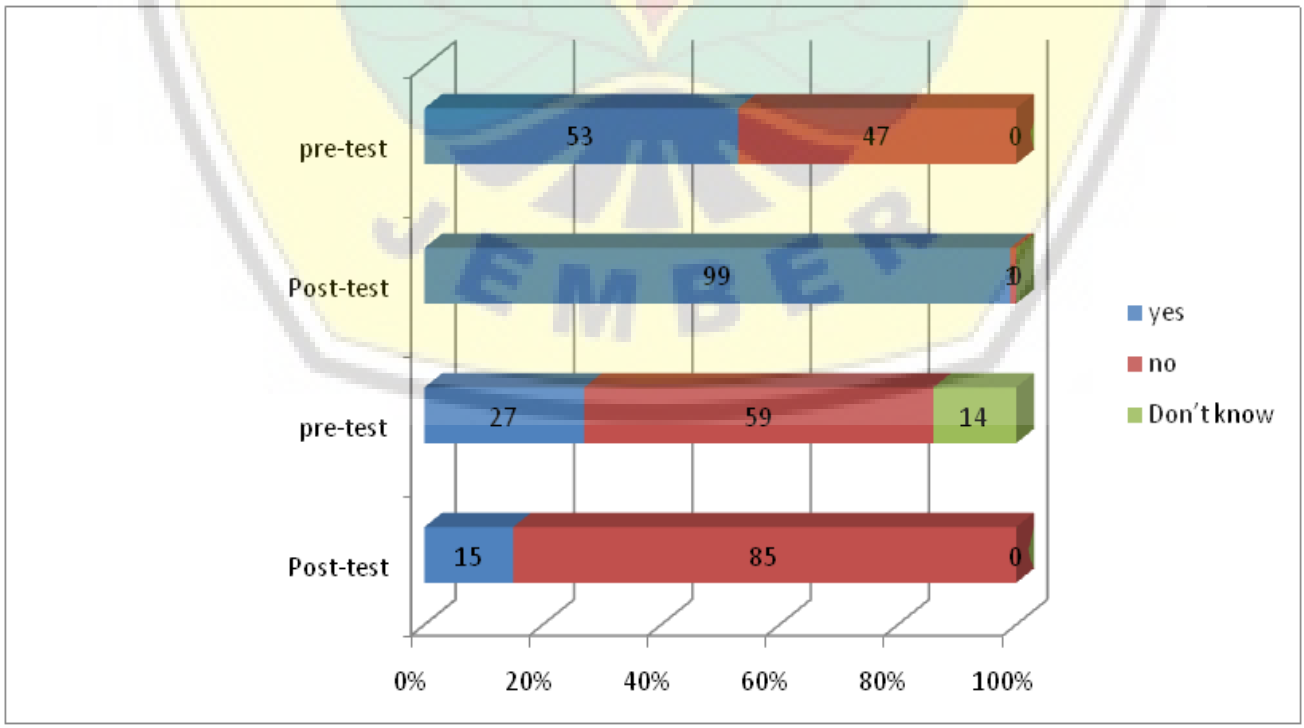

Figure 1: Knowledge about Prescription Writing

Awareness Regarding Prescription Error: Prior to intervention,70% & 50% of residents believed that computerized version of prescription would solve prescription error problem and pharmacists can help in reducing prescription error respectively, 20% & 35% of residents did not agree while 10% & 15% of residents were completely unaware of this. After intervention, 87% & 79% of residents believed that computerized version of prescription would solve prescription error problem and pharmacists can help in reducing prescription error respectively, 12% & 19% of residents did not agree while 1% & 2% of residents remained unresponsive about it.

When asked about reducing prescription error by using generic names instead of sound alike brand names,73% agreed, 14% did not agree and 13% did not know about it prior to intervention.

Post intervention, when they were again asked about reducing prescription error by using generic names instead of sound alike brand names, 97% agreed while only 2% did not agree.

77% of residents answered correctly regarding language of dosing instructions (Patient's own language) prior to intervention. Significant number of residents (82%) answered correctly post-intervention.

When residents were asked about authentication of handwritten prescription, 59% of residents answered correctly (Signature, Doctor's name, Degree, Registration number) prior to intervention.

Post-intervention, When residents were asked about authentication of handwritten prescription, 85% of residents answered correctly (Signature, Doctor's name, Degree, Registration number). (See Figure 2).

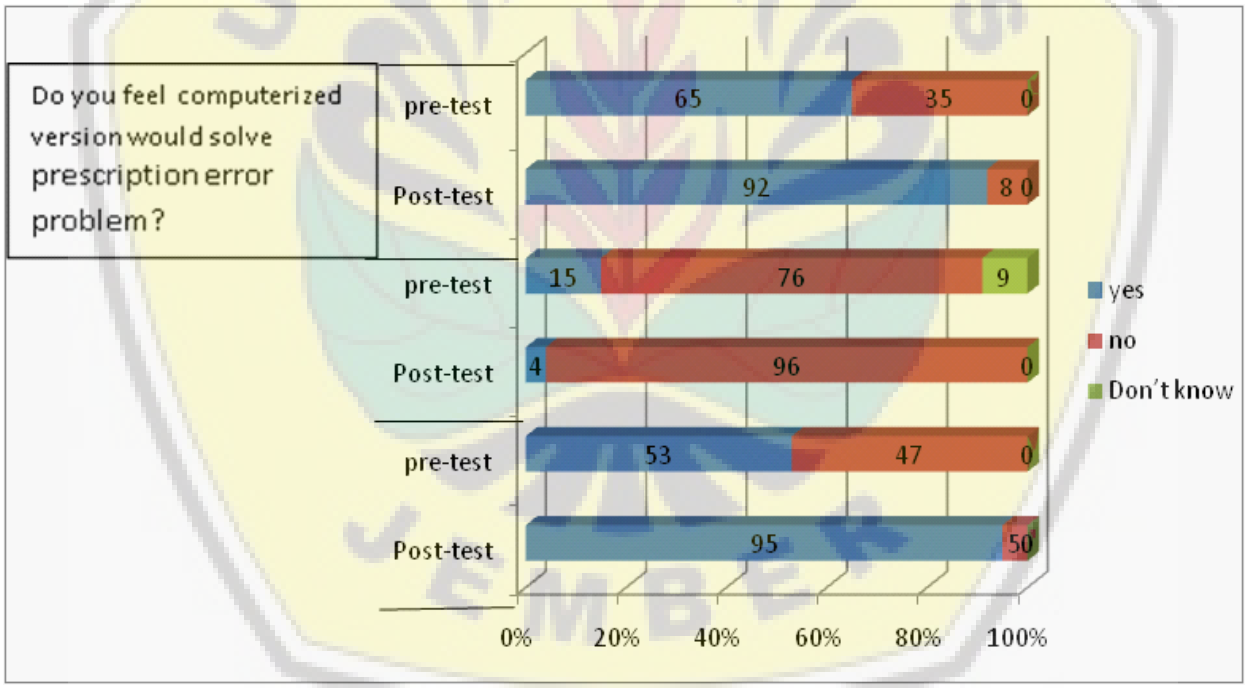

Figure 2: Awareness Regarding Prescription Error

Knowledge, Attitude and Perception Towards Prescription Error: Prior to intervention, only 65% had idea about medico-legal consequences of prescription error while 92% had idea about medico-legal consequences of prescription post-intervention.

Prior to intervention, 15 % of residents believed that advertisement is allowed on prescription, 4 % of residents believed that advertisement is allowed on prescription post intervention.

When asked about the awareness regarding prescription of certain medications by specific speciality only, 53 % of residents were aware and 47 % of residents

did not prior to intervention. Post intervention, When asked about the awareness regarding prescription of certain medications by specific speciality only,95 % of residents were aware and 5 % of residents were not.

17 % of residents were aware of medico-legal consequences while 83 % were unaware prior to intervention. 45 % of residents were aware of medico-legal consequences while 55 % were not post intervention.

When asked about medico-legal importance of maintaining record of prescription 14% of residents knew while 86 % did not prior to intervention.

When asked about medico-legal importance of maintaining record of prescription 52 % of residents knew while 48% did not post intervention. (See Figure 3).

Prescription Error:

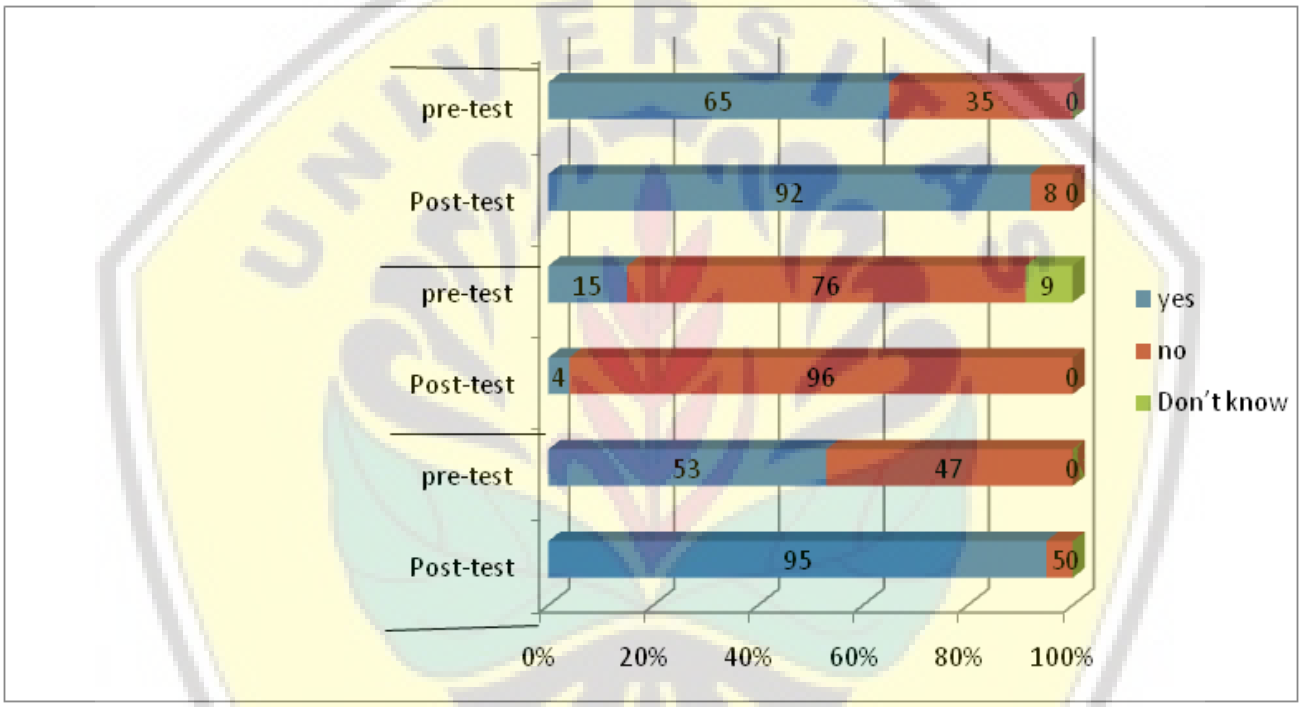

Figure 3: Knowledge, Attitude and Perception Towards

Discussion

Prescription error is the most serious of all types of medication error. It usually results in significant harm or death[17]. There is evidence of poor prescribing which includes errors, under-prescribing, over-prescribing, inappropriate or irrational prescribing by range of doctors across different setting.[7]

In the present study, an educational intervention was done to sensitize residents from clinical fields regarding prescription errors and measures to prevent them. Initially, a questionnaire covering various aspects of prescribing was administered to them to check their prior knowledge. A sensitization programme was then conducted to improve prescribing and reducing error which can help to improve patient's safety as well as doctors' safety because it has medico-legal aspects also. After a week, residents were administered same questionnaire again and both pre and post intervention data were compared.

Tesh et al include "the prescription of medication by brand (instead of generic) name" under prescription error [18] When residents were asked if drugs should be prescribed by their brand name or generic name; prior to sensitisation, many of them misbelieved that it

should be by brand name while post sensitisation, many of them answered generic name. During the teaching session, they were told the advantages of prescribing in generic name and problems associated with brand names especially Look-alike and Sound-alike (LASA) medicines and their negative impact on patient care and prescribing doctor.

On being asked about the details of prescription, most of them were not aware about recommended prescription format by Maharashtra Medical Council, MCI recognized abbreviations and parts of prescription. Their knowledge improved significantly post sensitization which was evident in the questionnaire filled by them.

Hospital pharmacists detect errors in around 1.5% of prescription items written [19]

Post sensitization, many of them started to feel that pharmacists could help in reducing prescription errors.

They also agreed that online prescription could reduce prescription errors. During the teaching session, residents were given detailed information on advantages of online prescription over the handwritten prescription as it is preserved for longer duration, it has better patient follow-up details and chances of doing prescription error becomes less likely. In addition to this, maintainence of record of prescription proves helpful for any medicolegal purpose.

Measures to reduce prescription error: The problem of prescription error has wide aspects hence a range of different corrective measures need to be taken. Junior doctors should be taught about selection and dosages of common drugs as well as drug- drug interactions and drug- disease interactions. They should be made aware of common prescribing errors. A practical test should be conducted in order to check their competence in a timely manner. Pharmacists should be trained regarding prescription errors and should also be asked to record their interventions in patient's notes. Elaborative charts and diagrams on walls of working room could prove beneficial.

Our results showed less improvement in knowledge about medicolegal consequences post- sensitization. It is therefore advisable to add certain aspects like interaction with medicolegal expert, demonstration of consequences through audio-visual aids or presenting any current scenario to the residents in the sensitization programme. This might prove fruitful and develop better understanding regarding importance of safeguarding doctors' own rights as well as promoting their safety.

Thus, sensitization as a whole can increase the knowledge regarding prescription writing and awareness about medicolegal consequences and importance of maintaining record of prescription. It would be advisable to include sensitization as a part of academic curriculum of resident doctors which will be beneficial for them as well as patients in long-term.

Conclusion

The study has highlighted the need to have sensitization programme for residents regarding prescription writing along with knowledge about medicolegal consequences which will further reduce the overall incidence of prescription error and promote patient's and doctor's safety.

Prevalence of Gross Motor Dysfunction in School Going Children with Flatfoot

Pranali Kakade[1], Mandar Malawade[2]

[1]Final Year Physiotherapy, [2]Associate Professor, Department of Paediatric Physiotherapy, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences, Karad

Abstract

Background: Arches of foot play an important role in our daily gross motor activities such as walking, running, jumping and standing and also act as shock absorber. Flat foot creates motor difficulties in activities require balance and stability as flatfoot alters the body's weight distribution and transmission mechanism. The children with flatfoot may have difficulty in lower limb gross motor function, any study has not been conducted on this topic previously, so indeed this made us to study the prevalence of gross motor dysfunction in school going children with flatfoot.

Objectives: To determine flatfoot in school going children (seven-twelve years).To determine prevalence of gross motor dysfunction in school going children with flat foot.

Method: Total 80 students were taken from different schools in this study having flat foot in age group of 7-12 years of age and both male and female students were taken. They were asses by using plantar arch index for flatfoot and were given lower extremity function scale questionnaire to fill. Later evaluation of gross motor dysfunction were done by analysis.

Result: The overall prevalence of moderately difficulty in physical activities was 8.37%, quite difficulty was 1.18%, little bit of difficulty was 16% and no difficulty was 73.5%. No significant difference were found in age wise and sex wise distribution with physical activities.

Conclusion: On the bases of the result it conclude that the difficulty is seen particularly in activities which requires dynamic stability than static stability activities in children with flat foot.

Keywords: *Flatfoot, gross motor, children, LEFS, plantar arch index.*

Introduction

Flat foot (pesplanus) is a term used for less develop longitudinal arches. The longitudinal arches consist of medial longitudinal arch and lateral longitudinal arch.[1] Arches are supported by intrinsic and extrinsic muscles of the sole with the plantar ligaments, plantar aponeurosis and shape of the bones. The ligaments which mainly takes part are spring ligament, interosseous ligament, long plantar ligament and short plantar ligament. [1] In pesplanus, the spring ligament and muscle tendons are stretched out so that the individual losses the function of medial longitudinal arch of foot during weight bearing, due to the displacement of the head of talus bone medially and distally from the navicular bone. The flatfoot can be diagnosed by various method, such as x-rays, clinical diagnosis and foot print analysis. Footprint analysis is a quick, simple, cost effective measure and is also readily

available method. Here measurements for footprint diagnosis is used by plantar arch index.[2]

Flatfoot in infants are consider normal because infants are born with flatfoot. The arch of the foot starts to develop around age of three to five years of life.[3] Flatfoot deformity may be classify as: 1) pathological 2) physiological. The pathological flatfoot is also called as rigid flatfoot and is characterised by a fixed arch that is not modified with weight bearing or non-weight bearing activities. The physiological flatfoot is also called as flexible flatfoot and is characterised by a normal arch without support and flattening of arch during standing or weight bearing activities.[3,4]

The risk factors for flatfoot are: lower age, overweight and obesity. In obese children the cause for flat foot may be the presence of plantar fatty pad under the medial longitudinal arch and also the excessive and continuous loading of foot by body weight.[4, 10] The arches of the foot play an important role in daily physical activities such as fast walking, running and jumping. and it also helps in weight bearing and body weight transmission to the ground.[5] Gross motor activities involve the large body movements. In typically developed child, by age of six month the child can bear almost all his weight when made to stand. By age of 12 months child can stand without support, by 15 month he walk alone and he runs by the age of 18 months. By age of two year child can walks up and downstairs (two feet per step) and also jumps. By age of four years child can hops on one foot and can go downstairs by alternate feet on steps.[6] In flatfoot the load distribution mechanism of body changes from lateral column to medial column of the foot, which may cause alteration in gross motor activities of lower limb in children with flatfoot.[4]

Material and Methodology

This was a study to find prevalence of gross motor dysfunction in school going children with flat foot. The study was carried out in Krishna College of physiotherapy, karad. An approval for the study was obtained from the protocol committee and ethical committee of KIMSDU. Individual were approach and those fulfilling the inclusive criteria were selected. The purpose was explained and written inform consent was taken prepared in accordance with the Helsinki Declaration from the children and their guardian those who are willingly to participate. The 80 students were taken from different schools in and around areas of karad for study. The inclusive criteria was both male and females in age group from seven-twelve years with flatfoot. The exclusive criteria wasindividual with any recent injury to lower limb, fracture of ankle joint, metatarsal joints or any bones of foot, gait abnormality due to any other causes than flatfoot and paresis or paralysis of lower limb. The participants were assessed for flatfoot by using footprints. The staheli plantar arch index was used to diagnose the flatfoot by footprints. The principle of these index is that the height of the arch is related to footprint. The PI was measured by dividing the width of central region by width of heel region on footprint, it is calculated as: a line drawn tangent to the medial of forefoot edge and heel region, then a perpendicular line drawn medially to laterally from the midpoint of tangent line in central region of footprint (A) and similar another perpendicular line drawn from heel region (B). The PI was then calculated by dividing value A with value B. The PI more than 1.15, was consider as flatfoot.[2, 7]Further subjects with flatfoot were evaluated for gross motor function of lower limb by using lower extremity function scale questionnaire.[8] It has total 20 day to day activities of lower limb with maximum 80 points. The candidates were divided in age wise group as 7-8 years, 9-10 years and 11-12 years and in gender wise group as male and female. The total score was calculated and statistical analysis and interpretation was done for each candidate to find out the prevalence of gross motor dysfunction in school going children with flat foot.

Statistic Analysis: For sample size following formula was used

$n=4pq\div L^2$

(p= 74%, q= 26% and L= 10%)

$= 4\times26\times74\div10\times10 = 76.96$

n= 80

The paired T test and two-way ANOVA were used for analysis of data. Statistical analysis of the recorded data was done by using the software SPSS version 20. The p value is less than 0.001 which is significant but in the age group of 7-8 years, 9-10 years and11-12 years the p value is more than 0.05 which is not significant and also in the gender wise group the p value is more than 0.05 which is not significant.

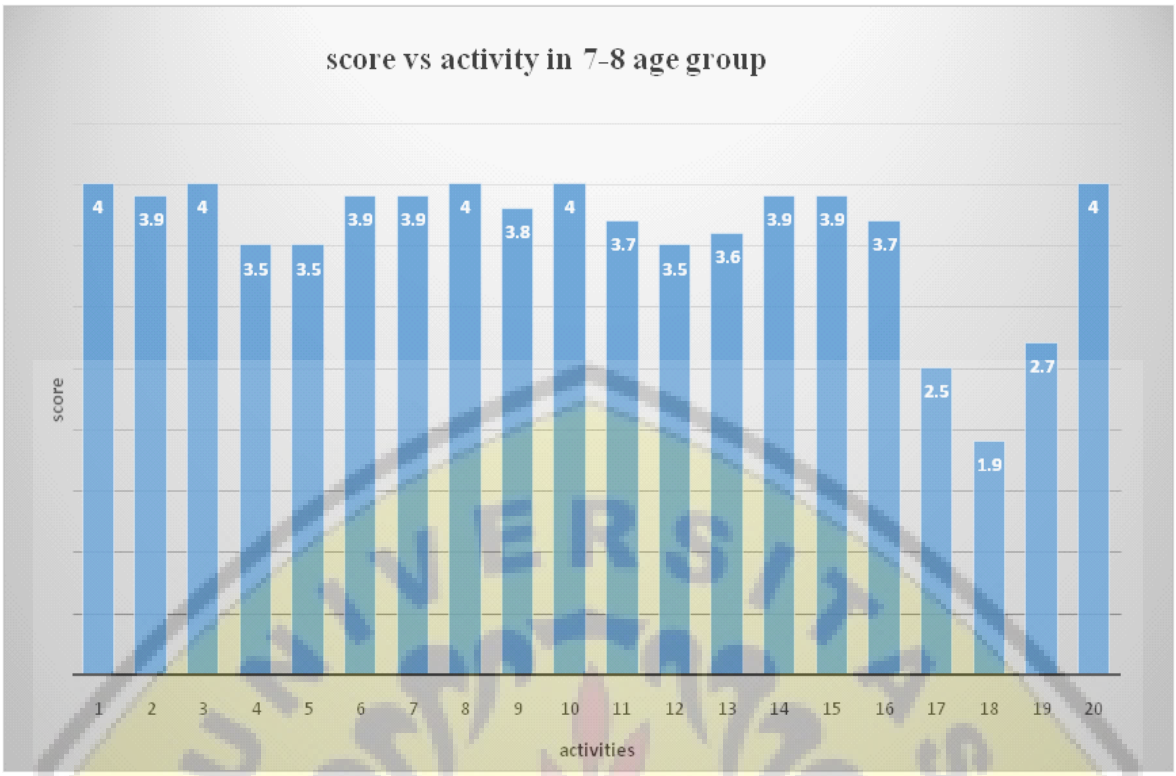
Result

The overall prevalence of moderately difficulty in physical activities was 8.37%, quite difficulty was 1.18%, little bit of difficulty was 16% and no difficulty was 73.5%. No significant difference were found in age wise and sex wise distribution with physical activities.

Table No. 1: 7-12 Year Children with Flat Foot

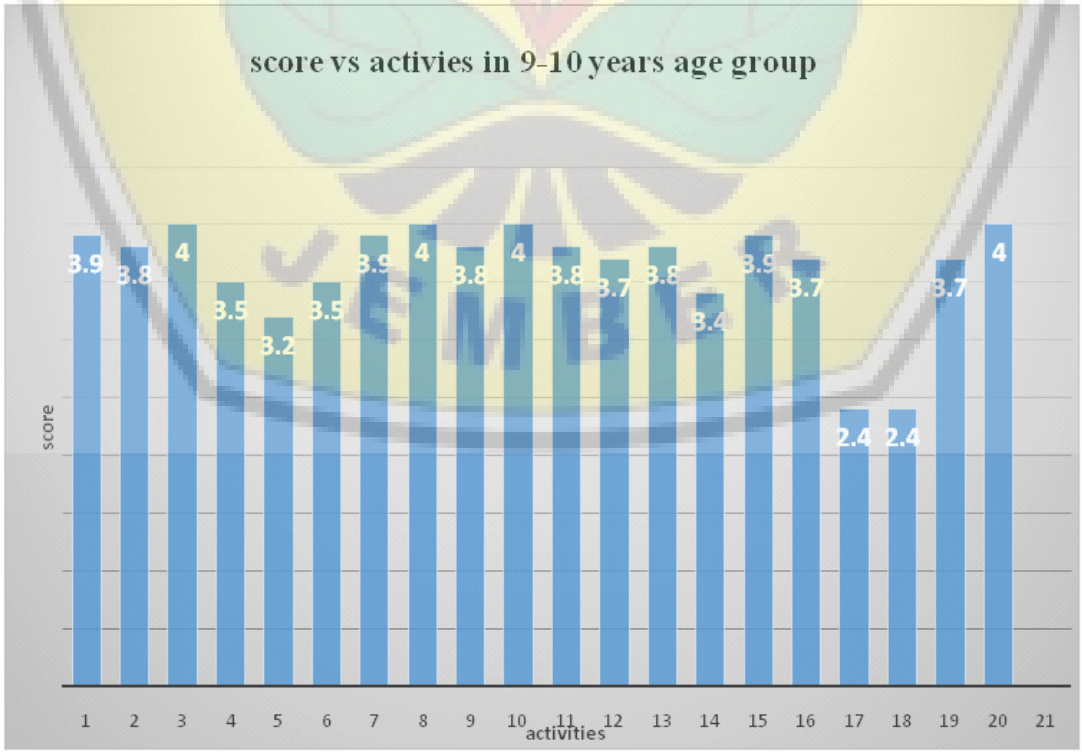
Activities	Mean	Median	SD	P Value
Activity 1	3.9	4	0.24	<0.0001
Activity 2	3.8	4	0.33	<0.0001
Activity 3	4	4	0.00	-
Activity 4	3.6	4	0.60	<0.0001
Activity 5	3.3	4	0.79	<0.0001
Activity 6	3.6	4	0.59	<0.0001
Activity 7	3.9	4	0.30	<0.0001
Activity 8	4	4	0.00	-
Activity 9	3.8	4	0.34	<0.0001
Activity 10	4	4	0.00	-
Activity 11	3.7	4	0.48	<0.0001
Activity 12	3.6	4	0.64	<0.0001
Activity 13	3.7	4	0.49	<0.0001
Activity 14	3.4	4	0.69	<0.0001
Activity 15	3.9	4	0.15	<0.0001
Activity 16	3.7	4	0.53	<0.0001
Activity 17	2.4	3	0.74	<0.0001
Activity 18	2.1	2	0.69	<0.001
Activity 19	3.3	4	0.86	<0.001
Activity 20	4	4	0.00	-

SD-Standard deviation, (n =80)



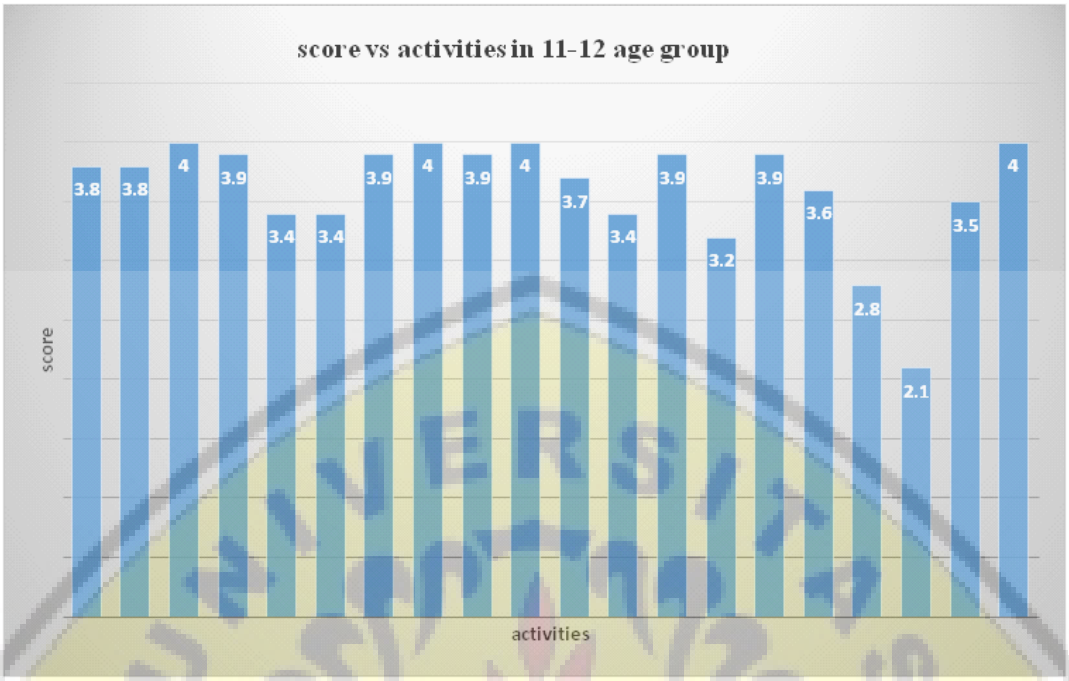
Graph No. 1: Activities in 7-8 Years Age Group

Interpretation: In age group 7-8 years the activity number 18 which is making sharp turns while running is quite a bite of difficult to 30%, moderately difficult to 43% and a little bit of difficult to 26% of candidates. and the activity number 19 which is hopping is quite a bit difficult to 10%, moderately difficult to 36%, little bit of difficult to 26% and no difficult to 26% candidates



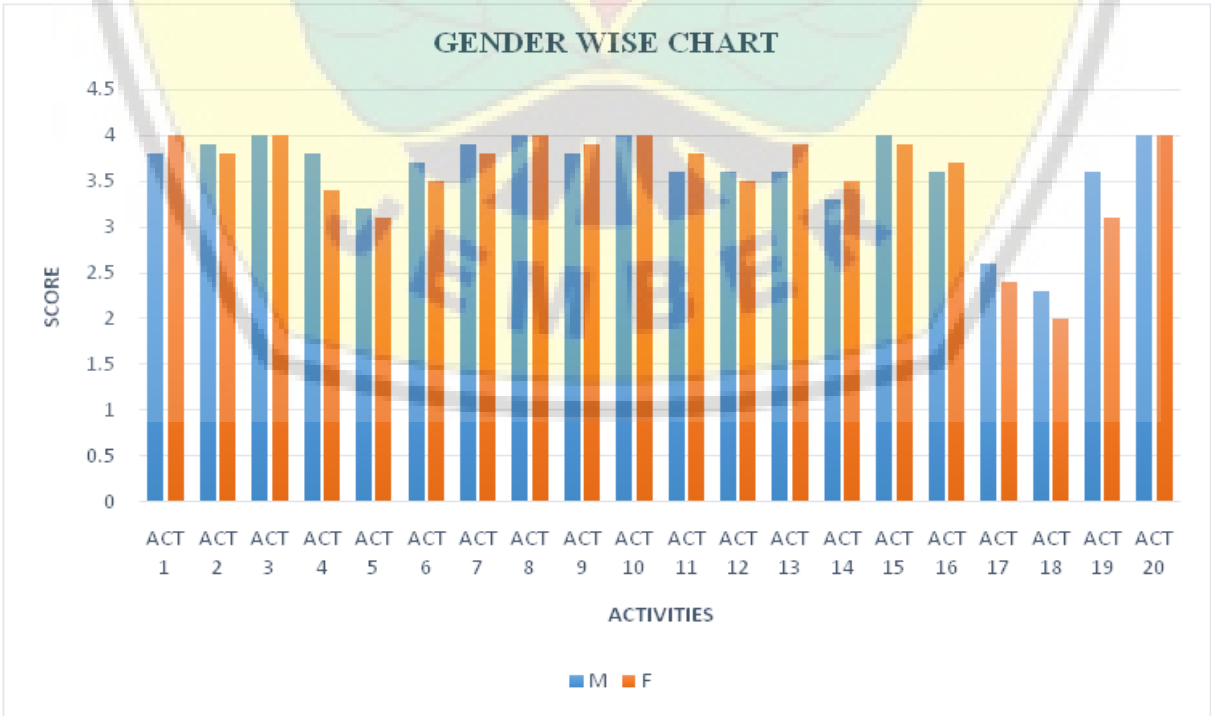
Graph No. 2: Activity in 9-10 Years Age Group.

Interpretation: In age group 9-10 years the activity number 17 which is running on uneven ground is quite a bit difficult to 11.4%, moderately difficult to 40% and little bit difficult to 45.7% candidates.



Graph No. 3: Activities in 11-12 Years Age Group

Interpretation: In age group 11-12 years the activity number 18 which is making sharp turns while running fast is quite a bit difficult to 20% moderately difficult to 46.6% and little bit of difficult to 33.3% candidates. The activity number 17 which is running on uneven ground is quite a bit difficult to 6.6%, moderately difficult to 26%, little bit difficult to 40% and no difficult to 26%. and the activity number 19 which is hopping is quite a bit difficult to 6.6%, moderately difficult to 6.6%, little bit of difficult to 13.3% and no difficult to 66.6% candidates



Graph No. 4: Gender Wise Comparision of Activities.

Interpretation: There is no significant difference seen in LEFS score of male and female candidates with flatfoot.

Discussion

The arches of foot play an important role in dynamic and static balance of individual. The arches of foot may also have a certain impact on muscle strength of lower extremity and physical performance in children. They also supports the body weight and absorbs ground reaction force during physical activities or sports. [9] In flatfoot the foot is mostly pronated which affect the stability and balance of individual. It also causes difference in body weight distribution mechanism.[10, 11] Plantar arch index is a clinical measure to measure arch height in individuals. The aim of the study was to find out the prevalence of gross motor dysfunction in school going students with flatfoot. The study was carried out and result was drawn by using plantar arch index for flatfoot assessment and lower extremity functional scale questionnaire for gross motor activities.

In this study we found that there was difficulty in some physical activities in students from 7-12 years in both males and females participants. The limitation of this study is that, study is limited to particular geographical area and with limited sample size.

According to Chang-Ryeol Lee and Myoung Kwon Kim stated that the activities of most muscle in the subjects with flatfeet were significantly different from the muscle activities in the subjects with normal feet at different gait velocities on an ascending slope. Our study supports this article as we found most of the students have difficulty while making sharp turns while running fast or running on uneven ground. This article also indicated that the abductor halluces muscle do not have proper function as a dynamic stabiliser of medial longitudinal arch.[12] This may be the reason for participants for difficulty in activities require dynamic balance as there is less activation of abductor halluces in flatfeet children which is dynamic stabiliser of medial longitudinal arch. [12, 13] Whereas, in our study we found that there was difficulty in certain physical activities in flatfoot children may be due to less activation of abductor halluces muscle and change in weight bearing mechanism in foot. According to Hyounk he found no significant difference in dynamic balance ability between normal, pronated and supinated foot groups. The study was done with group of normal, supinated and pronated foot individuals. The dynamic balance was checked by using a star excursion balance test (SEBT). [14]

The article of Zhao X, Tsujimoto T, Kim B, Tanaka K stated that there was no significant relationship was found in arch height and physical performance measure, our study do not support this statement as we found significant difference in physical performance in flatfoot children. The author also found the more muscle strength in ankle muscle of lower arch participants.[15]For this further analysis is required.

Conclusion

On the bases of the result it can be concluded that there was difficulty in performing certain physical activities to students with flatfoot. The difficulty is seen particularly in activities which requires dynamic stability than static stability activities. No significant difference was found in age wise and sex wise categories.

Conflict of Interest: The authors declare that there are no conflicts of interest concerning the content of present study.

Salivary Flow Rate and pH in Patients with Potentially Malignant Disorders and Oral Cancer

Prashaanthi N.[1], Sreedevi Dharman[2]

[1]Graduate Student, [2]Reader, Department of Oral Medicine, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Aim: To assess the salivary flow rate [SFR] and pH in patients with potentially malignant disorders and oral cancer.

Materials and Method: Salivary samples were collected from 15 healthy individuals and 15 patients with potentially malignant disorders and oral cancer (5 patients with Leukoplakia, 5 patients with Oral Submucous Fibrosis, 5 patients with Oral Cancer). Unstimulated whole saliva (UWS) was collected using the spitting method. The salivary flow rat [SFR] was evaluated with the micro pipetting technique and a portable pH meter, equipped with a microelectrode, was used to measure pH. The results were tabulated and statistically analyzed.

Results: The data analysis showed that FR and pH showed statistical significant differences ($p < 0.005$) between patients with potentially malignant disorders and oral cancer (FR = 0.34 mL/min, pH = 6.85) and the patients without oral lesions (FR = 0.61 mL/min, pH = 7.09).

Conclusion: In our study, there is a relationship between potentially malignant disorders, oral cancer and alteration of pH and SFR. Due to tobacco habits either smoke or smokeless forms can cause alterations in tobacco users which render oral mucosa vulnerable to various oral and dental diseases. Reduced Salivary flow rate and pH has a correlation with potentially malignant disorders and oral cancer.

Keywords: *Human saliva, Salivary pH, Salivary flow rate, Oral cancer, potentially malignant disorders.*

Introduction:

Saliva is produced by three pairs of major glands and numerous minor salivary glands located in the oral cavity. The parotid, submandibular and sublingual salivary glands contribute to 90% of total saliva secretions, while minor salivary glands contribute to the remaining 10%. The amount of saliva secreted by the major and minor glands is referred to as whole saliva. In the resting (unstimulated) state, approximately two-thirds of the total volume of the whole saliva is produced by submandibular glands. Upon stimulation, the parotid glands are responsible for at least 50% of the total volume of saliva from the mouth. Sublingual glands contribute to a small percentage, both in the unstimulated or stimulated states of the salivary glands.[1,2]

Changes in salivary composition and flow rates maycompromise the integrity of the soft and hard tissues in the oral cavity, because saliva functions include food and bacteria clearance, mastication and digestion, lubrication, antimicrobial defense and buffering effect.[3,4]

The buffer capacity of saliva is an important factor, which plays a role in the maintenance of salivary pH

Corresponding Author:
Dr. Sreedevi Dharman

and in dental remineralization. Bicarbonate is the main buffer that opposes acids, but is completely effective only at high salivary flow rates, because its concentration increases markedly with SFR rise. The buffer capacity of saliva basically depends on bicarbonate concentration; it correlates with salivary flow rate, as any factor decreasing salivary flow rate tends to decrease its buffer capacity and to increase the risk of caries development.[5-9]

The evaluation of the unstimulated whole salivary flow rate (UWSFR), is carried out by an easy, non-invasive and comfortable procedure, which favors its use in clinical environmental (public or private). UWSFR is the basal rate of saliva flow and it's the greatest contributor to the total salivary output during the diurnal cycle. The collection of unstimulated "whole saliva" reflects basal SFR; this fluid is present in our mouths for about 14 hours a day and its secretion provides protection to oral tissues. Moreover, several pathological and behavioral factors could influence UWSFR: e.g. oral and systemic diseases, drugs intake, nutrition, stress, sports activity.[10,11]

The aim of our study were: to determine the UWSFR and corresponding pH in a sample of 30 patients in which 15 patients were healthy individuals and 15 with oral lesions, (5 with leukoplakia, 5 with oral potentially malignant disorders and 5 with oral cancer) and to evaluate the correlation between salivary flow rate and pH in patients with oral lesions.

Materials and Method

A cross-sectional descriptive study was conducted in Saveetha dental College with patients visiting the outpatient department. The study involved 30 subjects of which 15 were healthy individuals and 15 were patients with oral lesions (5 with Leukoplakia, 5 with oral potentially malignant disorders and 5 with oral cancer). They were informed of the purpose of the studyand enrolled after giving their signed informed consent.

Inclusion and Exclusion Criteria: Individuals who have completed 35 to 55 years of age and present on the day of clinical examination were included in the study. Patients with habit of consuming tobacco both smoke and smokeless were included in the study. Patients with systemic illness, hepatic or cardiac failure, immunocomprised individuals, under hypertensive drugs were excluded from the study.

The enrolled subjects were asked to follow the protocol norms: In the two previous weeks, they had to avoid consumption of chewing gum; the day before saliva collection, they had to be relaxed and not to practice sports activity. In the sampling day participants had to be free from symptom of fever and/or cold; if they were hungry or thirsty, they could eat or drink water, but later immediately they had to clean their teeth with a provided toothpaste; during the last hour before the salivary collection, it was not permitted them to eat, to drink or to smoke.[11]

Method of Collection

The saliva was collected in morning hours to avoid diurnal variation using the spitting method. Unstimulated whole saliva (UWS) was collected for a 5 min time span: the undisturbed subject, sitting in a comfortable position, swallowed residual saliva present in the mouth before the beginning of the collection and then, with the head down and mouth slightly open, saliva was allowed to drip from the lower lip into a pre-weighed, sterile plasticcontainer. In the last few seconds of the 5 min, saliva accumulated in the mouth was spat out into the plastic funnel. No other conscious movements of the oral musculature were made during the collection.[11]

The salivary samples were measured using a micropipette determine the UWSFR, which was calculated asml/min of the collection period.

The UWSFR was reported as to mL/min; pH was immediately detected on samples by a portable pH meter equipped with a special 5 mm diameter electrode.[11]

Results

The results shows that the mean and S.D of salivary flow rate in healthy individuals were (0.61+_0.119) and in patients with oral cancer and potentially malignant disorders were (0.34+_0.106) which was statistically significant with p value<0.05. The mean and S.D of pH in healthy individuals were (7.09+_0.322) and in patients with oral cancer and potentially malignant disorders were (6.85+_0.247) which was statistically significant with p value<0.05. [table 1]

The results shows that the mean and S.D of salivary flow rate in oral carcinoma individuals were (0.26+_0.055), in patients with OSMF and Leukoplakia were (0.34+_0.089) and (0.38+_0.110). The mean and S.D of pH in oral carcinoma individuals were (6.98+_0.239) and in patients with OSMF and

Leukoplakia were (6.82+_0.239) and (6.74+_0.251). The mean and SD of individuals with potentially malignant disorders (OSMF and Leukoplakia) and oral carcinoma showed no statistical significance. This infers that the salivary flow rate and pH in patients with PMD and oral carcinoma individuals were similar. [table2] Figure 1,2,3,4 respectively, Bar graph shows the salivary flow rate and pH in patients without oral lesions, with OSMF, Leukoplakia and Oral carcinoma.

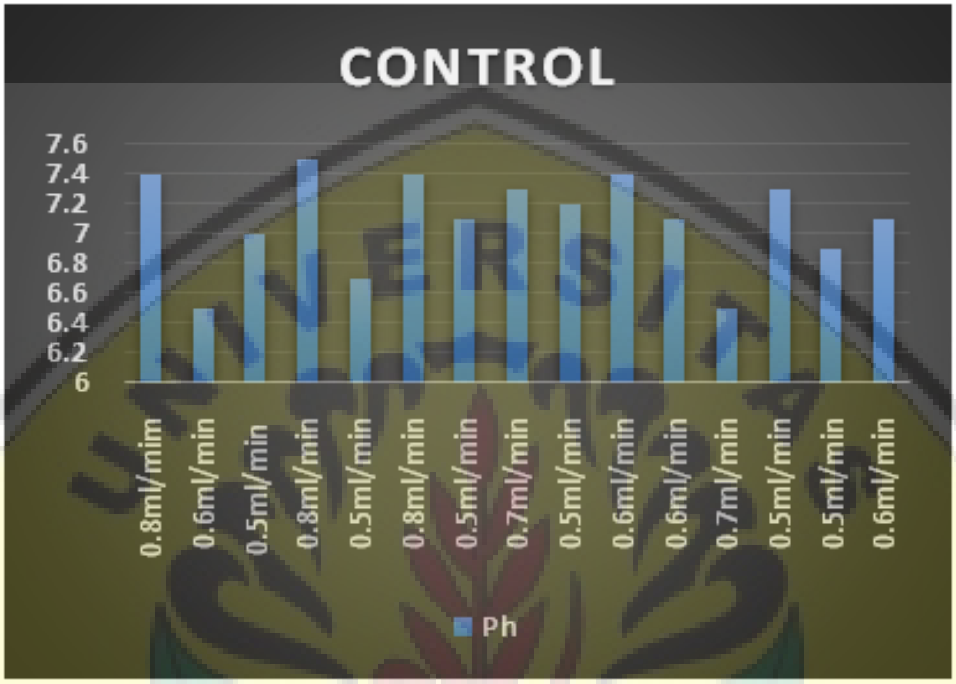

Figure 1: Graph showing the SFR and pH in patients without oral lesions

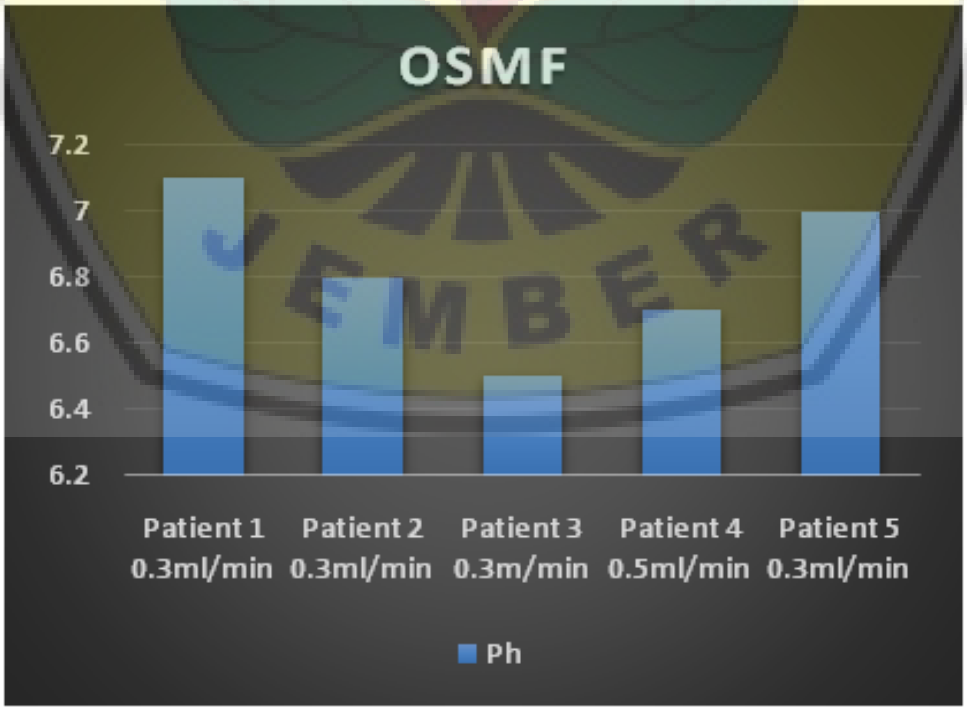

Figure 2: Graph showing SFR and pH in patients with OSMF

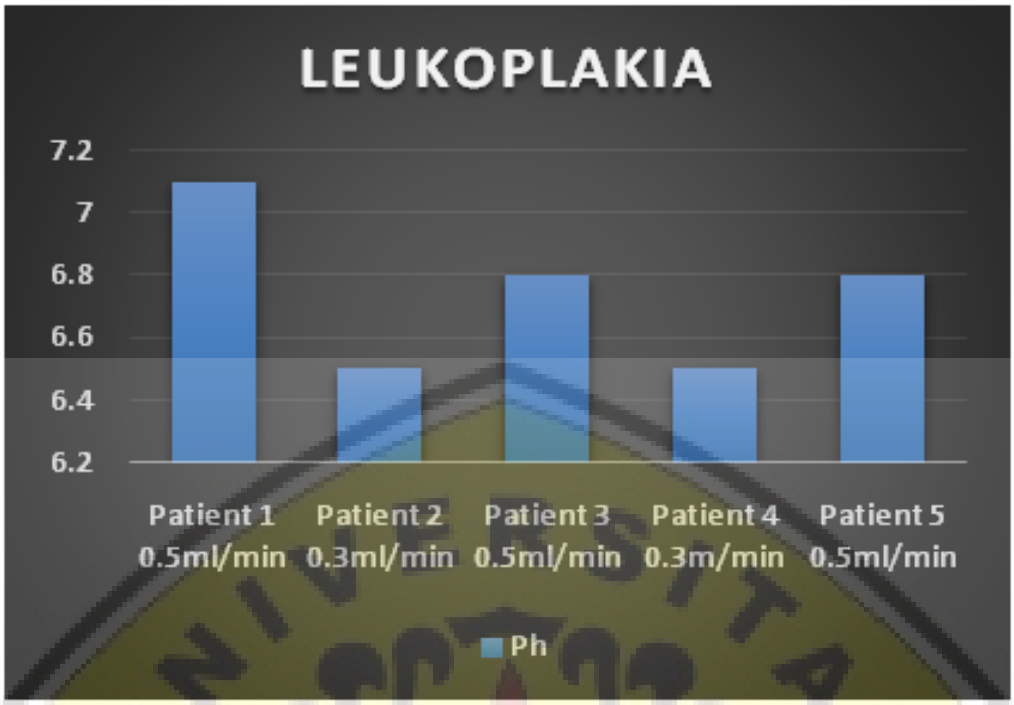

Figure 3: Graph showing SFR and pH in patients with Leukoplakia

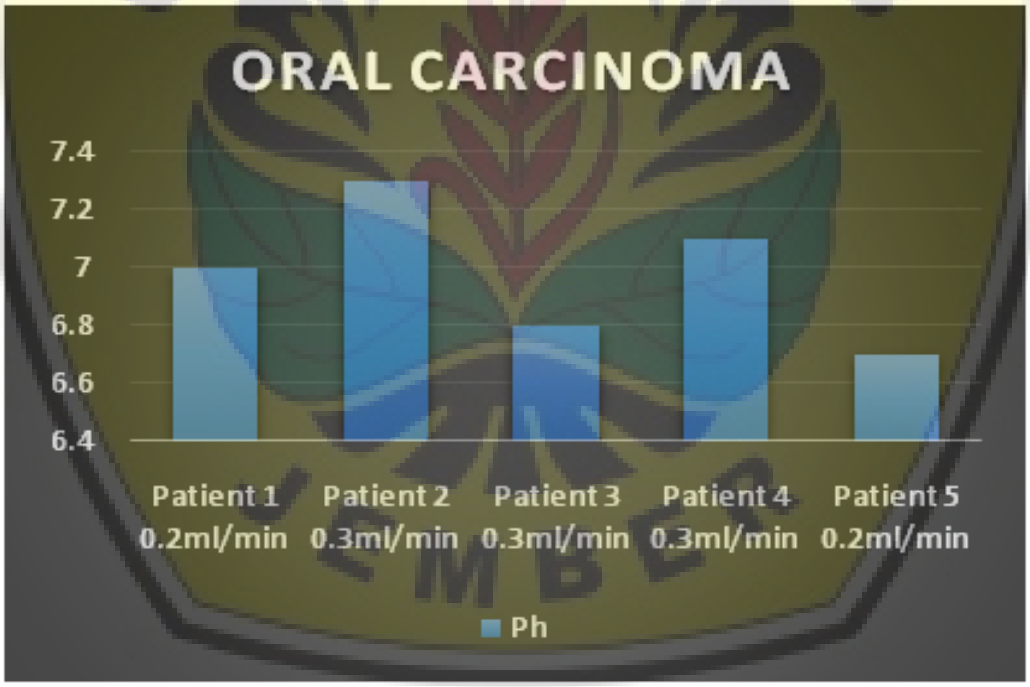

Figure 4: Graph showing SFR and pH in patients with Oral carcinoma

Table 1: Shows the mean and SD of control and study

Group	N	Mean±SD
Salivary flow rate(study)	15	0.34±0.106
Salivary flow rate (control)	15	0.61±0.119
pH (study)	15	6.85±0.247
pH (control)	15	7.09±0.322

Table 2: Shows the mean and SD of PMD and oral carcinoma

Group	N	Mean±SD
Salivary flow rate (OSMF)	5	0.34±0.089
Salivary flow rate (LEUKOPLAKIA)	5	0.38±0.110
Salivary flow rate (ORAL CARCINOMA)	5	0.26±0.055
pH (OSMF)	5	6.82±0.239
pH (LEUKOPLAKIA)	5	6.74±0.251
pH (ORAL CARCINOMA)	5	6.98±0.239

Discussion

Cancer of the oral cavity accounts for approximately 3% of all malignancies diagnosed annually in 2,70,000 patients world-wide. Oral cancer is the 12th most common cancer in women and the 6th in men. Many oral squamous cell carcinomas develop from potentially malignant disorders (PMDs). Lack of awareness about the signs and symptoms of oral PMDs in the general population and even healthcare providers is believed to be responsible for the diagnostic delay of these entities.[12]

During areca nut chewing lot of chemicals & metals like copper, iron are leached out into saliva, which in turn alter the property and composition of saliva. In betel quid chewer's variations in the SFR, pH has been reported. Production of reactive oxygen species is enhanced by the presence of alkaline pH of saliva. It is believed that tobacco usage on a long-term basis can decrease the sensitivity of taste receptors, leading to decreased salivary reflex. It is hypothesized that long-term tobacco usage might lead to altered taste receptors' response, changing the SFR. Unstimulated whole mouth SFR and salivary pH play an important role in the causation of various oral changes and conditions. [13,14]

A study by Nishant, et.al in 2015 observed that areca nut chewing leads to release of chemicals thereby altering the salivary SFR and pH in OSMF subjects.[13] This is correlated with our study which reveals decrease in salivary pH and SFR in patients with OSMF.

Neeraj Grover, et.al also observed significant relation of low salivary pH in subjects consuming smoke and smokeless form of tobacco compared to controls which is correlated with our study. Reaction with bicarbonate buffering system by the loss of bicarbonate, turning saliva more acidic could alter electrolytes and ions and thereby alters the pH as they interact with the buffering systems of saliva.[15]

Singh M, et.al also observed that mean of salivary flow rate and pH in smokers was lesser than the mean of salivary flow rate and pH in non smokers.[16]

In our study there is reduced salivary flow rate and pH in patients with Leukoplakia and OSMF which has an association with smoke and smokeless form of tobacco. Individuals with chronic use of tobacco as smoke or smokeless form can lead to potentially malignant disorders. These potentially malignant disorders have the highest risk of malignant transformation. Individuals with chronic use of tobacco as smoke or smokeless form can be assessed for the salivary flow rate and pH which would enable us to detect early diagnosis of potentially malignant disorders and initiate appropriate medication and cessation of habit at an earlier stage which would prevent the risk of malignant transformation and improve the quality of life in individuals.

Our study showed that there is a decrease in the salivary flow rate and pH in patients with oral cancer and potentially malignant disorders due to tobacco consumption when compared with healthy individuals.

Conclusion

There is a significant decrease in salivary flow rate and pH in patients with oral cancer and potentially malignant disorders due to tobacco consumption. Due to tobacco habits either smoke or smokeless forms can cause alterations in tobacco users which render oral mucosa vulnerable to various oral and dental diseases. Reduced Salivary flow rate and pH has a correlation with potentially malignant disorders and oral cancer.

Knowledge and Practices towards Antibiotics among People Residing in an Urban Slum of Nagpur

Pratha Sharma[1], Ajeet Saoji[2], Prachi Saoji[3]

[1]Student, NKP Salve Institute of Medical Sciences and Research Centre, Nagpur, [2]Professor and Head, Department of Community Medicine, NKP Salve Institute of Medical Sciences and Research Centre, Nagpur, [3]Assistant Professor, Department of Applied Mathematics, Shri Ramdeobaba College of Engineering & Management, Nagpur

Abstract

Introduction: The excessive, imprudent use of antibiotics has led to them becoming increasingly ineffective. Educating the public is key to changing the status quo, but it must be guided by an accurate understanding of the existing practices and knowledge gaps.

Aims: To study the prevalence of antibiotic use among the study population and evaluate its socio-demographic correlates. Additionally, to assess knowledge towards antibiotic use and resistance among respondents.

Material and Method: A questionnaire-based, cross-sectional survey was carried out in an urban slum of Nagpur in May-June, 2017. Sample size of 281 was computed and population was sampled by systematic random sampling. Recent history of antibiotics was obtained and its relationship with socio-demographic characteristics of the population analysed using Chi-square statistics (significance – $P < 0.05$). Knowledge about antibiotic use and resistance was assessed by the response to12 knowledge statements.

Results: The prevalence of antibiotic use among the study participants was 13.9%, with 28.3% of it being obtained over-the-counter. 71.7% participants said they completed the course. Overall knowledge was average in 78.6% of the participants. No significant association of the prevalence of antibiotic use with socio-demographic variables was established.

Conclusions: The present study reported that the prevalence of antibiotic use and over-the-counter purchase was low, while compliance was encouragingly high. Also, socio-demographic correlates seemed to have no bearing on antibiotic use. Most participants showed an average level of knowledge overall, but the results varied with respect to specific aspects of antibiotic use and resistance.

Keywords: *Antibiotic, antimicrobial, resistance.*

Introduction

Effective antibiotics have been one of the pillars that allow us to live longer, stay healthier and enjoy benefits from modern medicine. Antibiotic resistance leads to ineffective treatment, higher medical costs, prolonged hospital stays, increased mortality and economic burden on families and societies.(1)

WHO's first global report on antibiotic resistance in 2014 reveals that it is no longer a prediction for the future; it is happening right now in every region of the world and has the potential to affect anyone, of any age, in any country.(2)

Sweden instituted STRAMA – a multidisciplinary AMR surveillance programme – in 1994.(3) Today, it has

e-mail: psprathasharma891@gmail.com

one of the lowest rates of antibiotic use and resistance in the world.[3,4] Years later, a number of countries – including India - now have national AMR surveillance programs, yet public awareness on the issue remains low. Continual education of the people will corroborate the gains of surveillance in tackling antibiotic misuse and consequent resistance.

Aims and Objectives:

1. To study the prevalence of antibiotic use among study population.
2. To assess knowledge towards antibiotic use and resistance among respondents.
3. To evaluate socio-demographic correlates of antibiotic use.

Materials and Method

A community-based cross-sectional study was conducted in an Urban Health Training Centre (U.H.T.C.) area, which is an adopted area under the administrative control of a tertiary care teaching hospital of Nagpur.

As per 76% prevalence of antibiotic use estimated by previous literature[5], we calculated a sample size of 281 with 95% confidence level and 5% margin of error, using Open Epi software (version 3.01).

According to the data available at the U.H.T.C., the total number of houses in the field practice area was 3383. A list of all the houses was prepared. Sampling interval was calculated by dividing the total number of houses by the estimated sample size, i.e. 281.

Sampling interval = number of houses/sample size = 3383/281 = 12.03

It was then rounded off to the nearest whole number, i.e., 12. Then, a random number was generated using random table and used as a start for the sampling procedure. Thereafter, every 12th house from the list was sampled till the required sample size was met.

If the house was locked, 2 additional visits were made on two different days. If it was found to be locked during the revisits as well, it was labelled as 'non-contactable' and was excludedf rom the study. The house immediately to the right side of it was then considered for the study.

Eligibility Criteria: Within each sampled house, only one person, ≥ 18 years of age and literate, was randomly selected for the purpose of the study.

Exclusion Criteria: Illiterate participants and those unwilling to give consent.

After thorough explanation regarding the study, written and informed consent was obtained.

Data Collection tool: Data collection was done by face-to-face interviews using a pretested and structured questionnaire. The questionnaire was adapted from previous studies and modified and validated to suit the studypopulation. It comprised of three parts, of which –

Part 1 consisted of the socio-demographic characteristics of the participants, like age,gender, religion, education, occupation, marital status, type of family, socio-economic status etc.

Part 2 was designed to assess antibiotic usage among participants in the previous three months. Once we confirmed whether the participant had taken antibiotics or not, they were requested to provide further information regarding the source and reason for taking antibiotics and asked whether the course was completed.

Part 3 consisted of 12 statements to evaluate knowledge towards antibiotic use and antibiotic resistance. Each question was responded to by the participants on a dichotomous scale of'yes' or 'no'. Correct response for a statement was given a score of '1', while an incorrect response was scored 'zero' (the highest attainable score being 12). The scores were not constructed in reference to an absolute gold standard, but rather used for their relative values as simple tools in the analysis of knowledge of antibiotic use and resistance. Based on their scores, the participants were classified as having poor (score 1-4), average (5-8) and good (9-12) knowledge.

Participants were given the option of having the questions read to them and their answers recorded by the researcher, or they could read and answer the survey on their own.

The questionnaire (along with the informed consent form) was made available in both English and the local language, Marathi. This was done to alleviate any discomfort and to increase the participation rate.

Statistical Method: Descriptive statistics were reported using percentages. Associations were evaluated using a bivariate analysis by chi-square test ($P < 0.05$

was considered statistically significant). All analyses were performed using OpenEpi (version 3.01) software.

Results

The study population consisted of 281 participants. Majority of the participants (179) were females, while 102 participants were male. Of all the participants, 76.1% were under 47 years old; the highest number being those between 18-27 years of age (30.2%).Most participants in the study were graduates or of a higher qualification (34.2%), followed by intermediate/diploma holders (32.3%) and high-school educated individuals (22.8%). Very few (3.6% and 7.1%, respectively) had only primary or middle school education. In terms of their employment status, 164 (58.4%) of the participants were unemployed, while 117 (41.6%) were employed; this is probably because the door-to-door study was carried out during the day and also included retirees and not due to a lack of employability in the population. Their socioeconomic status was calculated using the B. G. Prasad classification, according to which most of the participants belonged to class III (28.1%), II (23.5%) and I (22.4%).

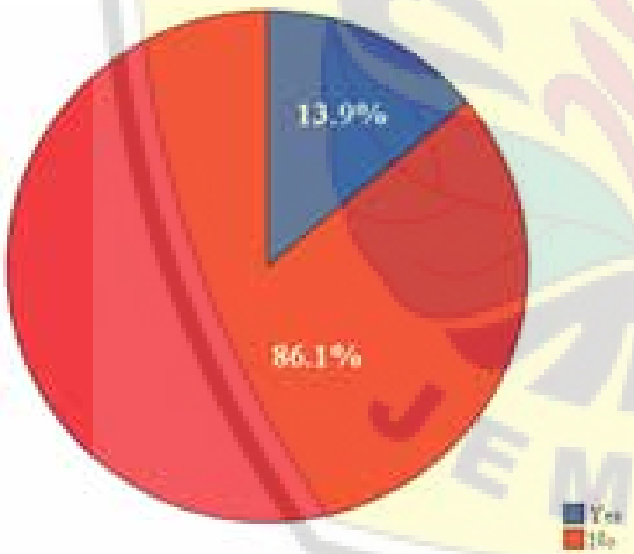

Figure 1: Prevalence of Antibiotic Use in Study Population (N=281)

During the study, out of 281 participants, only 39 (13.9%) reported the use of antibiotics in the previous three months (*Figure 1*). The most common reason for antibiotic use was cough and cold (36.7%). Other reasons (20.4%) were sinus infection, skin infection, post-surgical use, root canal and other dental treatment of the 39 participants with a history of antibiotic use, 11 (28.3%) admitted to having self-medicated (based on a pharmacist's or relative's advice, or past experience). Irrespective of the source of prescription, 28 (71.7%) participants stated that they completed the course. The pattern of antibiotic use is summarized in Table 1.

Table 1: Pattern of Antibiotic Use in Study Population

Factor	Response	n	Percentage
*1. Reasons for antibiotic use (n=49)**	Cough and cold	18	36.7
	Fever	11	22.4
	Headache	6	12.2
	Stomach-ache	4	8.2
	Others	10	20.4
2. Source of prescription (n=39)	Doctor	28	71.7
	Self-medicated	11	28.3
3. Completion of Course (n=39)	Yes	28	71.7
	No	11	28.3

*More than one response was permitted.

The assessment of knowledge regarding antibiotic use and resistance drew varied results. Based on their total scores, majority of the 281 participants (221, i.e. 78.6%) exhibited an average level of knowledge (score - 5 to 8); 13.5% and 7.8% of the participants had a good (score – 9 to 12) and a poor level of knowledge (score – 1 to 4), respectively (Figure 2). However, while 73.3% participants agreed that antibiotics can kill bacteria, only 25.3% knew that they are ineffective against viruses. Almost 60% participants knew that antibiotic overuse could lead to resistance. However, while nearly 70% thought that resistance is a property of bacteria, only 32% understood that it has no association with the human body. A significant number of participants also appeared to be misinformed regarding the indications of antibiotic use. *Table 2* summarizes the knowledge statements and indicates the number of participants who responded correctly to each statement.

Table 2: Number of Correct Responses to Each Knowledge Statement

Statement Number	Knowledge Statement	Number of participants who responded correctly	Percentage
1	Antibiotics can kill bacteria.	206	73.3
2	Antibiotics can kill viruses.	71	25.3
3	Antibiotics work on most coughs and colds.	156	55.5
4	Antibiotics are indicated to relieve pain/inflammation.	165	58.7
5	Paracetamol is an antibiotic.	162	57.7
6	The effectiveness of the treatment is reduced if the full course of antibiotics is not completed.	153	54.4
7	Antibiotics have no side effects.	131	46.6
8	Overuse of antibiotics can cause antibiotic resistance.	160	56.9
9	A doctor's prescription is not necessary for buying antibiotics.	187	66.5
10	The prescribed dose of antibiotics can be terminated if the symptoms improve.	166	59
11	Antibiotic resistance is a property of bacteria.	189	67.3
12	Antibiotic resistance is a property of the human body.	90	32

The data was also analysed for possible associations between the level of knowledge and the socio-demographic characteristics of the study population. No significant association knowledge could be established with age (P 0.2), literacy status (P 0.2), employment status (P 0.5) or socioeconomic status (P 0.9) of participants.

Discussion

The study found that out of the 281 participants, only 13.9% reported having taken antibiotics in the last 3 months, as opposed to 86.1% who did not. Two different Malaysian studies in the recent past quoted figures of 16.5% and 28.9%, respectively.[6,7] These differences, despite comparable sample sizes, are probably attributable to differences in the period of recall as well as seasonal variations in the susceptibility to some common bacterial infections; and possibly, the cultural characteristics of the study population. Out of the 39 participants (13.9%) who reported antibiotic usage, 28.3% participants admitted to having self-medicated with antibiotics. A study on self-medication in Pune indicated a much lower percentage of 10.32% of all antibiotics being self-medicated.[8]

Patient compliance was significant, with 71.7% of the participants with recent history of antibiotic use stating that they completed the course, irrespective of the source of prescription. A study in Kuwait reported a similar compliance (64.9%).[9] The most common reason for antibiotic usage was cough and cold (36.7%), followed by fever (22.4%). Most other studies also stated reasons similar to ours for antibiotic use.[6,7,10,11]

The assessment of knowledge about antibiotic use and resistance in our study population showed that 221 (78.6%) participants had an average level of knowledge on the subject. In comparison, a similar study in Penang, Malaysia recorded 54.7% of the participants as having moderate knowledge about antibiotic use and resistance.[7] Another study in Andhra Pradesh reported a poor level of knowledge on antibiotic use in 65% of its participants.[12] However, delving deeper into these questions threw up some interesting observations.

The participants' response to statements 1 to 5, which required them to be cognizant of the definition of antibiotics, was alarmingly poor. While most participants (73.3%) correctly identified that antibiotics are used against bacteria, only 25.3% knew that they are ineffective against viruses. A number of similar studies carried out in Kuwait, Malaysia, Andhra Pradesh and Northern India also indicated a significant lack of knowledge about the difference in indication of antibiotics in bacterial and viral infections.[7,9,11,12] Two inferences we made during the interviews may account for this disorientation. Firstly, many of the participants, while being aware of the term 'antibiotics', were unable to accurately identify them as drugs used to treat infectious diseases, particularly bacterial infections.

Moreover, they often seemed unaware of the difference between bacteria and viruses, probably owing to the fact that in practice, we commonly refer to them both as "germs". This could also explain why 55.5% participants believed that antibiotics can cure most coughs and colds, which are more commonly viral. In contrast, a Swedish survey found almost two-thirds of its study population to be aware of their effectiveness against bacteria as well as their lack of it, against viruses.[13] This is a noteworthy indication of the success of their surveillance program.

In response to statements regarding practices, 66.5% of the 281 participants were aware that antibiotics can't be bought without a doctor's prescription; while 60.4% disagreed that an antibiotic course could be terminated as soon as symptoms improved. While this number was better than the one reported in the Andhra Pradesh study (25.6%)[12], it pales in comparison to the Swedish survey, where 95.5% of the participants knew that a prescribed antibiotic course must be completed, even if the symptoms subside.[13]

With respect to the statements specific to antibiotic resistance, we found that 58.2% of the participants responded correctly to statement 8 ('Overuse of antibiotics can cause antibiotic resistance.'), a finding corroborated by a similar percentage obtained from a study in Malaysia.[7] Here, it must be noted that while responding to statement 8, many participants were not familiar with the term 'antibiotic resistance', but knew by experience that antibiotics could become ineffective on overuse. In order to maintain the neutrality of the interview, they were allowed to respond to the statement with this interpretation. Further, while half the participants (50.5%) believed that antibiotic resistance was a property of bacteria (statement 11), nearly 70% believed that it was a property of the human body (statement 12). Interestingly, some participants agreed with both the statements, indicating the belief that it was a property of both, the bacteria as well as the human body. This may, in part, be attributable to their perception of antibiotic resistance. The Swedish study also reported a similar observation. Over 80% participants were aware that bacteria can become resistant to antibiotics, but 84% of the participants also agreed with the statement that it's the human body which develops resistance.[13]

In our study, we were unable to determine any significant association between antibiotic use and socio-demographic factors. This result may have been obtained due to the relatively small sample size and the short duration of our study. A study covering a larger number of participants over a longer period of time may yield different results.

Conclusion

- The prevalence of antibiotic use was considerably low in this study, while their administration with prescription and patient compliance was substantial.
- Participants' awareness about over-the-counter sales of antibiotics and course completion was encouraging; but simultaneously, their ignorance regarding the indications of antibiotic use could possibly be a factor in their OTC purchase.
- The most surprising result obtained from the study was that almost 60% of the participants seemed to be instinctively aware of the phenomenon of antibiotic resistance, if not the term itself.
- There's an urgent need to educate the general public. The efforts are already visible in the form of posters and video messages played in some hospitals and pharmacies, but it needs to reach a much wider audience, as through mass media campaigns.
- The scarcity of literature analysing possible correlations between socio-demographic factors and antibiotic use suggests a new avenue for research to further understand patient behaviour.

Poly Pharmacy Usage among Geriatric Population at Rural Health Centre, Kamineni Institute of Medical Sciences, Narketpally

Ratna Balaraju[1], K. Chandra Sekhar[2], Chandrasekhar Vallepalli[3], M.M.V. Prasad Sharma[4]

[1]Assistant Professor at Kamineni Institute of Medical sciences, Narketpally, Telangana, Conducted the Study, [2]Professor & Faculty at Hay Al Akhdar Post Graduation Training Centre for Saudi Board of Family Medicine, Buraidah, Qassim Province, Saudi Arabia, Systematic Preparation and Editing the Paper, [3]Assistant Professor of Community Medicine, SVIMS-Sri Padmavathi Medical College for Women (SPMCW), Tirupati, Andhra Pradesh, Research Idea and Data Analysis, [4]Professor & HOD Community Medicine at Kamineni Institute of Medical Sciences, Narketpally, Telangana, Timely Guidance and Research Encouragement

Abstract

Background: Poly pharmacy can be defined as more than two drugs, where as in case of elderly population the intake number of drugs varies. Hence polypharmacy definition in elderly people is different. On the whole throughout the world among the geriatric population, there is increase number of drugs in take was observed.

Objectives: To find the prevalence of polypharmacy, demographic and other factors association with polypharmacy among the geriatric population. Methodology: A cross sectional institutional based study was conducted from April 2019 to June 2019 among the elderly population at the field practice area of Rural health Centre of Kamineni Institute of Medical Sciences, Narketpally. A total of 97 persons were interviewed and information collected and confidentiality of individual information maintained. Necessary statistical tests like simple proportions and chi square tests were applied. Results: In the present study, about 45.3% were males and only 54.7% were females. Among the study population 72.1% were literates. Approximately,70.1% were using polypharmacy medication in their routine life. Near to 57.7% individuals were having osteoarthritis problem. There was statistically significant association was found between female sex and polypharmacy more than 5 drugs use. Conclusions: Based on the study results, polypharmacy using people were more as the study group is above 60 years of age group and naturally in that age more health problems are there. Osteoarthritis problem is common problem identified as per the self report and history. Need life style modifications before development of any disease, primordial and primary prevention strategies will help for the reduction of such problems in the coming future.

Keywords: *Age, Sex, literacy, Occupation, Health Problem, Polypharmacy.*

Introduction

Throughout the world elderly population is increasing due to our quality life increasing, diagnostic facilities and modern treatment facilities availability to the general population was increased. Rising standards of living also a another entity to increase our life expectancy in India. At the time of our Independence, average life expectancy of the person is 34 years and now almost doubled by the span of 70 years duration. Polypharmacy is the use of multiple medications by a patient, generally older adults (those aged over 60 years). More specifically, it is often defined as the use of five or more regular medications. It sometimes alternatively refers to purportedly excessive

e-mail: cskalevaru@gmail.com

or unnecessary prescriptions. The term Polypharmacy lacks a universally consistent definition. Polypharmacy is most common in the elderly, affecting about 40% of older adults living in their own homes.

As a result of having multiple diseases, the elderly people may be on multiple drugs, leading to potential drug interactions, adverse drug reactions and poor compliance.[13]Previous studies in different countries have also found inappropriate prescriptions among in the elderly.[5,6]Elderly people are now the most rapidly growing part of the patient population worldwide, needs to more focus on primary prevention of diseases and improvements in healthcare for the younger ill patient .[7]Elderly persons are exposed to Polypharmacy because of multiple chronic conditions. Many risk factors for Polypharmacy have been identified including age, race/ ethnicity, sex, educational achievement level, health status and number of chronic diseases. However, drugs prescribed for individual diseases have not been analyzed. [8]

As the number of medicines taken and the incidence of adverse drug reactions are more in this age group, it becomes increasingly important to study patterns of drug use and also should maintain some interval of time between one tablet to another tablet to avoid drug -drug interactions.[9] Very few studies on drug utilization in geriatric patients are available, especially in India.[10,11] Keeping this in mind, the study was done with the broad aim of polypharmacy usage among the geriatric population and the socio-demographic characteristics, morbidity pattern, associated co-morbidities and commonly prescribed medications.

Objectives:

1. To find the prevalence of polypharmacy among the geriatric population.
2. To determine demographic and other factors association with polypharmacy among the geriatric population.

Methodology: Target population: Geriatric population of Rural health centre of Kamineni Institute of Medical Sciences, Narketpally.

Study design: cross sectional study

Study duration: April to June 2019

Sample size: 97 individuals. (Based on prevalence assumption is 50%, 95% confidence interval and precision is 10%). WHO Statistical package for sample size calculation was used for the estimation of the sample size.

Sampling Procedure: At Rural health centre, above 60 years old individuals visiting to the Rural health Centre, every alternative patient was selected by systematic random method. Each patient explained about importance of the study and usefulness of the study in our rural settings and health care centre. Oral informed consent was obtained from each and every patient.

Statistical Analysis: Simple proportions and chi square test were applied for categorical analysis of variables.

Inclusion Criteria: Patients aged 60 years and above Willing to participate in the study.

Exclusion Criteria: Non co-operative patients Age below 60 years of age group. Mentally retarded patients and comatose patients.

Results

In the present study about 97 geriatric population was participated, among them approximately 83.5% were in the age group of 60-70 years and only 16.5% were more than 70 years age group. In the study group, 45.3% were males and 54.7% were females. Near to 70% of the study population were literates. In the present study, about 67% were unemployed people.

Table 1: Polypharmacy use, frequency and duration of use in study population

Polypharmacy Use	Number of Patients	Percentage
Yes	68	70.1%
No	29	29.9%
Total	**97**	**100%**
Frequency		
< 5 drugs	21	30.9%
> 5 drugs	47	69.1%
Total	**68**	**100%**
Duration of intake of drug		
< 5 years	15	22%
5 - 10 years	25	36.7%
> 10 years	28	41.3%
Total	**68**	**100%**

Table 1 stated that 70.1% were using polypharmacy medication in their routine life. of which 69.1% were using more than 5 drugs.

Table 2: Self reported health problems in the study population (n-97)

Health Problem/disease	Number	Percentage
Osteoarthritis	56	57.7%
Hypertension	38	39.2%
Cataract	30	30.9
Diabetes	22	22.7%
Acid peptic diseases	12	12.3%
Hearing loss	10	10.3
Neurological problems	5	5.2

Table 2 highlighted that out of 97 study population,56/97 (57.7%) individuals were having osteoarthritis problem. About 30.9% (30/97) people were having cataract and hypertension was about 39.2%.

Table 3: Sex according to Analgesic use in the study population.

Sex	Polypharmacy Use Yes	Polypharmacy Use No	Total
Male	20 (45.5%)	24 (54.5%)	44 (100%)
Female	48 (90.5%)	05 (9.5%)	53 (100%)
Total	68 (70.1%)	29 (29.9%)	97 (100%)

X^2 - 23.3, 1df, P - 0.001.

Table 3 revealed that about 90.5% of the females were using polypharmacy more than 5 drugs and males were about 45.5%.There was statistically significant association was found between female sex and polypharmacy more than 5 drugs use.

Discussion

Present study was conducted at Rural Health Centre, Kamineni Institute of Medical Sciences, during the period from the April to June 2019 among the geriatric population visiting to the centre to address the needs of geriatric population, drugs usage and demo-graphic characteristics of the study population. In the current study, about 45.3% were males and only 54.7% were females. Among the study population 72.1% were literates and less than 5000 rupees per month family income people was only 46.4%. Similar study conducted at Mandhya Institute of Medical Sciences, Karnataka revealed that male subjects were predominant (57.3%) compared to female subjects (42.7%). Majority of the patients belonged to the age group of 60–69 years[11]. Other studies conducted at different places where males patients were enrolled more and the gender distribution of our study subjects is in accordance with studies conducted by Shah *et al.*,[10] Nayaka *et al.*,[9]Binod *et al.*,[12]Kolhe*et al.*,[13] and Singh,[14] where the male patients were predominant.

In the present study stated that 70.1% were using polypharmacy medication in their routine life. of which 69.1% were using more than 5 drugs and also highlighted that out of 97 study population, majority of the individuals were having osteoarthritis problem. Other studies conducted at different regions of India and abroad stated that the total number of drugs prescribed for various disease conditions in the study population cumulatively was 1720. The mean number of drugs per prescription was 6.7. This is similar to the study that was conducted by Shah *et al.*[10] where the average number of drugs per prescription was 7.3 and contrary to the studies done by Weiss *et al.*[15] and Shenoy *et al.*[16] where the number was 5.

Polypharmacy is a major public health issue as well as an economic burden to all the nations across the world. In the current study out of 97 study population, 56/97 (57.7%) individuals were having osteoarthritis problem. It also leads to increased chances of adverse drug reactions. Hence, appropriate measures about awareness among the general public about drugs and its interactions and need to be taken to minimize the extent of polypharmacy in the society. There was statistically significant association was found between female sex and polypharmacy more than 5 drugs use ($P<0.05$). One of the limitation of the study was small sample size and cross sectional study. Generalisation of the present

study findings to the whole community is not advisable. Need long term similar cohort studies are required to substantiate the present study findings or results.

Conclusions: Polypharmacy was a common practice and observed among the female geriatric population. Most common geriatric health problem observed among the elderly population was Osteoarthritis health problem. About 2/3rd of the people were using more than 5 drugs for different health problems among geriatric study population.

To Evaluate the Revised National Tuberculosis Control Programme (RNTCP) through Assessment of Input Indicators and Age wise distribution of registered Pulmonary Tuberculosis Patients

Ravindra Y. Mandolikar[1], Raju Hanumant Patil[2], Narendra Shriram Madhekar[3]

[1]Assistant Professor, Department of Community Medcine, Shridevi Institute of Medical Sciences and Research Hospital Tumkur Karanataka, [2]Assistant Professor, [3]Professor, Department of Community Medicine Prakash Institute of Medical Sciences and Research (PIMS & R) Urun-Islampur, Sangli Road Maharashtra

Abstract

Background: Tuberculosis is not only a public health problem but also a social and an economic problem for mankind.

Objective: To assess the functioning of Revised National Tuberculosis Control Programme (RNTCP) at the level of Tuberculosis Units by considering infrastructural assessment of Tuberculosis Units and Designated Microscopy Centres (DMC) for staff position and their training.

Study Design: Cross-sectional study.

Setting: Under District Tuberculosis Centre, Satara involving all the ten Tuberculosis Units.

Participants: Fifty slides of sputum smear positive and fifty slides of sputum smear negative for tuberculosis were selected randomly.

Sampling: Simple random.

Study Period: From 2012 to 2014.

Results: DMC were adequate in number to cater the services to the areas of jurisdiction on an average 50,000 to 60,000 population under each DMC's in all Tuberculosis Units except Phaltan TU where each DMC's population exceeds above one lakh. Similarly post of Laboratory Technicians (LT) were vacant in DMC's of Patan, Vaduj and Bel-Air Tuberculosis Units. However majority of staff were trained under RNTCP except 7% of LT were not trained. Regarding DOT providers it was observed that 40% were untrained though they have been involved in giving DOTS therapy.

Conclusion: DMC were adequate in number. Majority of staff were trained under RNTCP except 7% of LT were not trained. Among all the detected cases of pulmonary tuberculosis, the productive age group of 25-45years which involves the active and the earning are the victims.

Introduction

National Tuberculosis Control Program[1] in India was started in 1962 with the aim to detect cases at the earliest and treatment. The program was implemented in the district through District Tuberculosis Centre (DTC) and the Primary Health Care Institutions with support

from state level organizations for coordination and supervision of the program.

Data on case finding and treatment at village and primary health centre level generated were passed through district to the state and then to the central level, which was reviewed at centre by Secretary and Director General Health Services, at state level by State Director of TB Training and Demonstration Centre and at District level was reviewed by District Tuberculosis Officer (DTO).[1] Despite the existence of National Tuberculosis Control Programme since 1962, tuberculosis remains the leading infectious cause of death in India. Around 2.2 million people are detected to have tuberculosis every year (25% of the global cases) and over 0.5 million die of this disease every year (17% of global tuberculosis deaths).[2] Total population suffering from active disease in India is 14 million of which 3 to 3.5 million are positive for sputum (20% to 25% of total). About one million sputum positive cases are added every year.[3]

India has the largest number of tuberculosis cases in the world, accounting for nearly one fifth of the global burden.[4] Tuberculosis is responsible for 5% of all death worldwide and 9.6% of adult deaths in the 15-59 years old economic productive age groups. [5] The case fatality rate of tuberculosis is high, approximately 50% of untreated cases die of the disease. Case finding is passive detection by means of a patient friendly and clinically efficient services based primarily on smear microscopy. Thus the current study is to assess the functioning of RNTCP at the level of Tuberculosis Units by considering infrastructural assessment of Tuberculosis Units and Designated Microscopy Centres (DMC) for staff position and their training and age wise distribution of pulmonary tuberculosis patients registered for treatment under RNTCP in Tuberculosis Units of Satara district, Maharashtra

Materials & Method: The study was carried out under District Tuberculosis Centre to assess the functioning of RNTCP at the level of Tuberculosis Units by considering infrastructural assessment of Tuberculosis Units and DMC for staff position and their training from 2012 to 2014. Ethical clearance was obtained from IEC prior to the commencement of the study.

Data Collection: The data collection regarding performance of each Tuberculosis Units was carried out retrospectively by obtaining information regarding case detection activities under RNTCP like staffing pattern, their position and training. Information was obtained pertaining to diagnostic activities. Investigator visited each TU and collected information through the laboratory registers, referral registers and treatment registers. To access the functioning of DMC in the form of microscopic activities like sample collection, slide preparation, procedure, examination of slides, disinfection of collected samples and slides. One DMC was selected randomly from each TU. Thus total 10 DMC were visited to access microscopic activities at DMC level.

From each DMC five sputum smear positive slides for tubercle bacilli and five sputum smear negative slides for tubercle bacilli were selected randomly. Thus fifty slides of sputum smear positive and fifty slides of sputum smear negative for tuberculosis were selected randomly and were cross checked for quality microscopy. All the selected slides were re-examined by the laboratory technician of respective DMC in the presence of Medical Officer and Investigator. The verification of obtained results were carried out in comparison with the original results by the Medical Officer in the presence of Investigator.

All the patients of randomly cross checked sputum smear positive slides for tuberculosis, that is 50 patients were telephonically interviewed for evaluation of quality services provided under Directly Observed Treatment Short Course Strategy (DOTS) at DOT providers level.

Statistical Analysis: Data was entered in Excel and Tuberculosis Units wise proportions and performance indicators pertaining to case detection were calculated for years 2012, 2013 and 2014.

For the evaluation of RNTCP following performance[6] indicators pertaining to input indicators were calculated and studied**: Input Indicators:** 1. Physical Infrastructure. 2. Staffing Pattern, Positioning and their Training

Results

Total 10 Tuberculosis Units are functioning under District tuberculosis centre Satara. The infrastructure of all the 10 Tuberculosis Units have been shown in Table No.1.

The highest population was covered by Tuberculosis Units Karad, Phaltan and Satara. The Karad TU consists of private Medical College, Krishna Institute

of Medical Sciences, which has its own Tertiary care centre along with DMC and DOT centre, where as Satara Tuberculosis Unit itself is located in District Tuberculosis Centre, Satara. It was observed that the average population covered by 1DMC was higher at sub-district level Phaltan (102625.8 per DMC) followed by Karad (70775.5 per DMC) and Satara (67237.3/DMC). Whereas Bel-Air and Vaduj sub district level has very low average population per DMC (36338.5 and 39627.8 respectively), however at District Tuberculosis Centre each DMC covered average population of 503800. This population under each DMC was found less than the population given as per the structure of RNTCP might be due to number of tribal, hilly and difficult areas located at sub-district level Vaduj, Bel-Air, Patan, Koregoan, Dahiwadi, Wai etc.

Total 400 DOT centres had been identified under satara district. Maximum were located at sub-district Umbraj (50), Patan (48) and Bel-Air (46), minimum DOT centres were functioning at sub-district level Vaduj (30), Koregaon (32) and Wai (33).

Table No. 1: Population distribution, Numbers of DMC's and DOT centres in various Tuberculosis Units under District Tuberculosis Centre, Satara

Tuberculosis Units	Population	DMC (n)	DMC/Population	DOT Centres (n)
Umbraj	326068	5	65213.6	50
Satara	403424	6	67237.3	42
Karad	424653	6	70775.5	42
Patan	313308	7	44758.2	48
Vaduj	237767	6	39627.8	30
Koregaon	260414	5	52082.8	32
Wai	283275	6	47212.5	33
Dahiwadi	245254	5	49050.8	36
Phaltan	410503	4	102625.8	41
Bel Air	218031	6	36338.5	46
Total	**3122697**	**56**	**53839.6**	**400**

Staff Position and Training: From the quarterly reports assessment of staff position and their training was done at both TU and DMC level.

At sub-district level all Medical officers and STLS of Tuberculosis Units were at place and trained under RNTCP. Whereas the post of STS was found vacant at Umbraj Tuberculosis Unit, rest of the places all STS are at place and trained. Out of all 56 DMC under District Tuberculosis Centre, Satara a post of Medical Officer was found vacant where the DMC is located in the Medical College at Karad Tuberculosis Unit. Similarly a post of LT was found vacant in one of the DMC of Tuberculosis Unit of Vaduj. All the existing Medical Officers were trained. It was found that 65 LT's were working at various DMC, of which only 26% LT's were posted through the RNTCP programme. Whereas rest of the LT;s were appointed under Malaria Programme and NRHM, however all existing LT's were trained under RNTCP except one LT from Koregaon Tuberculosis Unit, also it was found that 3 posts of LT's at DMC's of Patan, Vaduj and Bel-Air Tuberculosis Units. Total 2867 DOT providers were identified to provide directly observed treatment to all the tuberculosis patients under respective TU's. It was observed that 86.9% were trained under RNTCP who were acting as private practitioners, paramedical workers and anganwadi workers. Whereas 13.1% DOT providers were untrained and those were either neighbours, school-teachers, shop-owners/ previously cured patients.

It was seen that in 2012, a total of 2499 pulmonary tuberculosis were registered at district tuberculosis centre. Out of which highest number belonged to age group of 35-44 years and 25-34 years (23.8% and 23.5 % respectively)followed by 45-54 years (17.6 %) and 15-24 years (14%). The paediatric age group with pulmonary tuberculosis at DTC was 1.8%. and of age

group of >65years was 7.9%. The maximum number of pulmonary cases registered under RNTCP at sub district level were at Karad (13.3%), Satara (12.3%), Belair (12.1%) and Patan (11.9%) Tuberculosis Units and minimum registration was observed at Dahiwadi (6.6%) TU. The others tuberculosis units ranged from 9.5% to 8.4 %. Table 2

Table No. 2: Showing Age wise distribution of pulmonary tuberculosis cases at sub-district level in 2012.

TB Units	0-14yrs	15-24yrs	25-34yrs	35-44yrs	45-54yrs	55-64yrs	>65yrs	DTC
Umbraj	3 (6.5)	33(9.4)	58(9.9)	50(8.4)	44(9.8)	20(7.1)	5(2.5)	213(8.5)
Satara	11(24)	56(16)	59(10)	79(13.3)	42(9.5)	35(12.4)	25(12.6)	307(12.3)

DTC	46(1.8)	349(14)	588(23.5)	595(23.8)	441(17.6)	282(11.3)	198(7.9)	2499(100)

*figures in parenthesis are percentages

It was seen that in 2013, a total of 2651 pulmonary tuberculosis were registered at district tuberculosis centre. Out of which highest number belonged to age group of 35-44 years and 25-34 years (26.5% and 22.6% respectively)followed by 45-54 years (17%) and 15-24 years (15.1%).The paediatric age group with pulmonary tuberculosis at DTC was 1.5%. and of age group of >65 years was 7.1%. The maximum number of pulmonary cases registered under RNTCP at sub district level was at Belair (15.1%), Satara (13.6%), Karad (12.6%) and Patan (12.5%) Tuberculosis Units and minimum registration was observed at Dahiwadi (6.3%) TU. The others ranged from 9.7% to 7.01%. Table 3.

Table No. 3: Showing Age wise distribution of pulmonary tuberculosis cases at sub-district level in 2013

TB Units	0-14yrs	15-24yrs	25-34yrs	35-44yrs	45-54yrs	55-64yrs	>65yrs	DTC

*figures in parenthesis are percentages

It was seen that in 2014, a total of 2243 pulmonary tuberculosis were registered at district tuberculosis centre. Out of which highest number belonged to age group of 35-44 years and 25-34 years (26.7% and 23% respectively)followed by 45-54 years (15.7%) and 15-24 years (15.5%).The paediatric age group with pulmonary tuberculosis at DTC was 2.8%. and of age group of >65 years was 6.5%. The maximum number of pulmonary cases registered under RNTCP at sub-district level was at Belair (18.4%), Satara (13.8%), Patan (11.8%) and Karad (11%) Tuberculosis Units and minimum registration was observed at Dahiwadi and Vaduj (6.3% each) followed by Wai (6.9%) TU. The othes ranged from 9.4% to 7.3%. Table 4.

Table No. 4: Showing Age wise distribution of pulmonary tuberculosis cases at sub district level in 2014.

TB Units	0-14yrs	15-24yrs	25-34yrs	35-44yrs	45-54yrs	55-64yrs	>65yrs	DTC
Umbraj	6(9.8)	39(11.2)	52(10.1)	43(7.2)	35(9.9)	12(5.4)	8(5.4)	195(8.7)

Discussion

Total 10 Tuberculosis Units were functioning under District Tuberculosis Centre, Satara catering to the population 31, 22697. Total 56 Designated Microscopy Centres were functioning under District Tuberculosis Centre, Satara. On an average each DMC was catering for 5, 5760 population.

At Tuberculosis Units, 100% Senior Tuberculosis Laboratory Supervisor (STLS) were functioning, whereas one post of Senior Treatment Supervisor (STS) (10%) was vacant. All STLS and STS appointed at sub-district level were trained under RNTCP.

At DMC under each Tuberculosis Unit, total 56 post of Medical Officer were sanctioned of which 98% were in position and 2% vacant. However all the medical officers working at DMCs level were trained under RNTCP. Regarding Laboratory Technicians 67 posts of Laboratory Technicians (LT) were sanctioned of which 97% were in position and 3% were vacant. Among all the LT in position only 26% were appointed under RNTCP whereas majority (74%) were appointed under some other programs. Out of 65 in position LT only 97% were trained for RNTCP guidelines. Total 2867 DOT providers were found involved in providing DOTS therapy (Directly Observed Treatment), among them 87% were obtained training under RNTCP and they were either Health worker females or Anganwadi workers or Pharmacist. Whereas remaining were (13%) non-medical/paramedical persons who had not received any type of training. As per RNTCP all the posts at Tuberculosis Units (TU) as well as at DMCs must be 100% in position and all of them (100%) must be trained under RNTCP.[7]

N.Gupta et al[8] reported 12 to 40% of gap in trained Medical Officers (MO) and 20% in (LT. This was much higher than the current study. T.K Sen et al[9] also reported high proportion of vacant position of health workers and supervisors in comparison with the present study. Whereas V.M Bhagat et al[10] reported very less proportion (16.67%) of trained DOT providers which is very less in comparison with the present study.

In the present study most common affected age group was 35-44 years of age (23.5%, 26.5% and 26.7% respectively for the year 2012, 2013 and 2014)

followed by 25-34 years of age (23.5%, 22.6% and 23.5% respectively for the year 2012, 2013 and 2014). This is suggestive of physical and economically active group was affected predominately, which may lead to increase in dependency, loss of income, poverty has the main earning people have got affected by the pulmonary tuberculosis. Similarly extra-pulmonary tuberculosis was also found higher among same age groups. Similar findings was reported by Bawri S. et al.[11]

Conclusion

DMC were adequate in number. Majority of staff were trained under RNTCP except 7% of LT were not trained. Among all the detected cases of pulmonary tuberculosis, the productive age group of 25-45years which involves the active and the earning are the victims.

Acknowledgment: I would like to express my profound gratitude to all the participants.

Abstract

Background: Obesity is a health problem, causes serious complications. The mechanism of fat accumulation in the initial process of atherosclerosis is still unclear. The process occurs due to chronic inflammation where the indicator of atherosclerosis that related to inflammatory processes, such as levels of C-reactive protein (CRP) and tumor necrosis factor alpha (TNF-α)in the blood are higher in children with obesity.

Purpose: To examine the relationship of TNF-α, hsCRP and lipid profile with CIMT in obese adolescents.

Method: A cross sectional study was conducted on obese adolescents in Dr. Soetomo Hospital Child Health Unit from January until September 2018. Measurements of TNF-α, hsCRP and lipid profile were examine using ELISA method. CIMT was obtained through carotid ultrasound. TNF-α correlation, hsCRP and lipid profile with CIMT were analyzed using Pearson and Spearman Rho with significant value of P<0.05. Logistic regression analysis was carried out to determine the effect of cardiovascular disease risk factors on CIMT.

Result: 59 adolescents with central obesity were obtained, consisting of 32 (54.2%) boys and 27 (45.8%) girls. Total of 38 (64.4%) adolescents with dyslipidemia. There was no correlation between TNF-α, hsCRP, lipid profile and CIMT. The diameter of common carotid artery had a positive correlation with hsCRP (r=0.284;P=0.029). In girls, hsCRP had a positive correlation with the diameter of the left common carotid artery (r = 0.533; P=0.004). This correlation was not found in boys.

Conclusions: There was no correlation between TNF-α, hsCRP, lipid profile and CIMT.

Keywords: *Carotid intima-media thickness, hsCRP, Obesity, Llipid profile, TNF-α.*

Introduction

Obesity is a health problem throughout the world, causes serious short-term and long-term complications. In 2020, it is predicted that there will be an increase in the prevalence of cardiovascular disease by up to 16% and deaths from cardiovascular disease by 19% in adults aged 35-50 years and atherosclerosis.[1] Until now, the mechanism of fat accumulation in the initial process of atherosclerosis is still unclear, suspected the process occurs due to chronic inflammation. Obese children have a higher indicator of atherosclerosis than children without obesity. These indicators are related to inflammatory processes, such as levels of C-reactive protein (CRP) and tumor necrosis factor alpha (TNF-α) in the blood.[2,3)] Now, the combination of measurement of the media layer and intima in the communic carotid artery is used for early identification of systemic atherosclerosis.[4)] Obese children have higher carotid

intima-media thickness (CIMT) values than controls and are associated with higher BMI, waist circumference, triglyceride levels, cholesterol, LDL cholesterol and lower HDL cholesterol.[5]This study were conducted to examine the relationship of TNF-α, hsCRP and lipid profile with CIMT in obese adolescents.

Materials and Method

A cross-sectional study conducted at the Pediatric Departement, Dr. Soetomo General Hospital from January until September 2018. Inclusion criteria are adolescents aged 12-18 years with Body mass index (BMI)> $P9_5$of CDC charts. Exclusion criteria included: corticosteroid consumption within 6 months prior to study, dyslipidemia medication in 3 months prior to study, antibiotics, hormonal therapy, smoking, alcohol consumption, infection and suffering immune disorders or endocrine disorders. Data on physical activity and food intake were obtained by food recall on weekdays and holidays.

Anthropometric examinations were carried out by trained health personnels. Body weight was measured without shoes, using clothes weighing a maximum of 0.1 kg and without other accessories using digital scale (Seca, Germany). Body height was measured in an upright position, without shoes or head coverings using stadiometer (Seca, Germany).BMI was calculated by dividing body weight in kg with height in meters squared.

TNF-α, hsCRP and lipid were measure using ELISA method (in ng/L). Triglyceride is measured using TG-N Kit Autosera S (Sekisui Medical Co., Ltd., Japan), while LDL cholesterol, HDL and total cholesterol were measured using Cholestest®LDL, Cholestest®N HDL and Pureauto®S CHO-N (Sekisui Medical Co., Ltd., Japan). Dyslipidemia was established ifone of the cholesterol, HDL, LDL and triglyceride levels were increased as recommended by NCPE and the American Academy of Pediatrics.

CIMT was obtained by carotid ultrasound using a neck ultrasound (Toshiba, Japan), measured on the back wall of the left carotid artery to obtain atherosclerotic plaques, characterized by protrusion of blood vessel walls into the blood vessel lumen by >50% of the intima-media layer in the blood vessels.[6]

Statistical analysis were conducted using SPSS Statistics 21, including average value, drink value and maximum were analyzed using quantitative parameters. Correlation of TNF-α, hsCRP, lipid profile with CIMT and left internal carotid artery diameter were analyzed using bivariate analysis (significance at P value <0.05). Normal distribution were obtained. Pearson correlation carried out if the distribution were normal, otherwise Spearman's rho would be carried out.Quantitative parameters (CIMT, lipid profile levels, TNF-α and hsCRP) were analyzed in each group for distribution using Shapiro-Wilk test (significant at p value <0.05).

Results

A total of 59 adolescents with central obesity were obtained, consisting of 32 (54.2%)boys and 27 (45.8%) girls, meanwhile 38 (64.4%) adolescents were dyslipidemia. Table 1 lists characteristics of the subjects.

There were no significant differences between obese adolescents with dyslipidemia according to sex (p=0.057) and there were no significant differences in obese adolescents with hypertriglycerides by sex (Table 2).

The average TNF-α level in the obese group with dyslipidemia was 149.16 ng/l, while the non-dyslipidemia group was 143.58 ng/l. The average hsCRP level in the obese group with dyslipidemia was 2390.50 ng/ml, while the non-dyslipidemia group was 2161.06 ng/ml. The mean diameter of the left common carotid artery in the obese group with dyslipidemia was 6.51 mm, while the non-dyslipidemia group was 6.46 mm. Meanwhile, the average CIMT in the obese group with dyslipidemia was 0.54 mm, while the non-dyslipidemia group was 0.47 mm.

There was no correlation between hsCRP and CIMT (r = 0.072; P=0.589) but hsCRP had a positive correlation with the left common carotid artery diameter (r = 0.284; P=0.029). There was no correlation between TNF-α and the diameter of the common carotid artery or CIMT (r = -0.057; P=0.669; r = -0,089; P=0.501). There was no correlation between cholesterol, HDL, LDL and triglycerides with the diameter of the sininstra communic carotid artery (r=-0.209;P=0.113; r=-0.221;P=0.093; r=-0.014;P=0.289; r=-0.0125;P=0.346). There was no correlation between Cholesterol, HDL, LDL and triglycerides with CIMT (r=0.154;P=0.243; r=0.079;P=0.550; r=0.168;P=0.204; r=0.058;P=0.665).

There was no correlation between hsCRP and CIMT (r=0.072;P=0.589). However, hsCRP had a positive

correlation with the diameter of the left common carotid artery (r=0.284;P=0.029). There was no correlation between TNF-α and the diameter of the common carotid artery or CIMT (r=-0.057;P=0.669; r=-0.089;P=0.501). There was no correlation between cholesterol, HDL, LDL and triglycerides with the diameter of the sininstra communic carotid artery (r=-0.209;P=0.113; r=-0.221;P=0.093; r=-0.014;P=0.289; r=-0.0125;P=0.346). There was no correlation between Cholesterol, HDL, LDL and triglycerides with CIMT(r=0.154;P=0.243; r=0.079;P=0.550; r=0.168;P=0.204; r=0.058;P=0.665) (Table 4).

There was a positive correlation of hsCRP with the sininstra communist carotid artery diameter in female subjects (r=0.533;P=0.004 dan r=0.452;P=0.018), but no correlation between hsCRP and CIMT (r=0.048;P=0.811) (Table 5).

Table 6 shows no significant correlation between hsCRP and the diameter of left communist carotid artery and CIMT in boys.The effect of hsCRP on the diameter of left communist carotid artery has a model of regression with the common carotid artery diameter equation = 5,045 + 0.001 x hsCRP in girls, but not found in boys.

r	0.118
P	0.522

*P< 0.05 indicates statistical significance

hsCRP, high-sensitivity C-reactive protein; CIMT, carotid intima-media thickness.

Discussion

TNF-α is one of the main cytokines produced by fat tissue, especially monocytes, lymphocytes, adipose tissue and muscles. TNF-α activity increases the release of free fatty acids in adipocytes, blocks the synthesis of adipokine and interferes the phosphorylation of tyrosine residues in the first substrate of insulin receptors. TNF-α activates NF-κB, lead to enhancement expression of adhesion molecules on the surface of endothelial cells and vascular smooth muscle cells, causing inflammation in adipose tissue, endothelial dysfunction and eventually atherogenesis. TNF-α involved in insulin resistance and atherosclerosis by increasing the production of Th2 cytokines (IL-4 and IL-5) and increase the expression of leptin and IL-6 in fat cells. IL-6 stimulates acute phase protein production in the liver and increases CRP levels which lead to mild inflammation in endothelial cells, causing endothelialcell dysfunction, atherosclerosis and other cardiovascular complications.

CIMT is a structural marker of atherosclerosis. The combination of measurement of the media layer and intima in the communic carotid artery is used for early identification of systemic atherosclerosis now.[4] The average CIMT size of Asian children is 0.469-0,476 mm.[7] CIMT is associated with cardiovascular risk factors and the severity of atherosclerosis. Subjects with carotid plaque >1.9 mm had a 2.8-fold higher risk of cardiovascular events than subjects without carotid plaque (hazard ratio, 2.80; 95% CI, 2.04-3.84).[8]Plaque was not found in obese adolescents in this study.

In obesityoccurs a chronic inflammatory process, so obese children have a higher indicator of atherosclerosis than normal children that are related to the inflammatory process, such as levels of CRP in the blood.[2] Increasing of CRP levels and decrease of adiponectin indicate inflammatory process. The changes in CRP and adiponectin levels are associated with the increase of CIMT.[9] There is a positive correlation between CIMT and waist circumference with levels of TNF-α[10] and hsCRP[11]. Studies in Indonesia stated that TNF-α levels did not differ significantly in obese and non-obese groups[12]which is in line with this research. But another study showed there was a positive correlation between obesity and an increase in CRP levels.[13]

31% of obese children with metabolic syndromes.[14] Dyslipidemia (impaired lipid profile) is a component of the metabolic syndrome and a risk factor for atherosclerosis. Dyslipidemia associated with obesity is characterized increase of triglyceride levels, decrease of HDL cholesterol levels and an increase in LDL cholesterol levels.[15] Silva et alstated HDL cholesterol levels had a negative correlation with CIMT.[13]CIMT is associated with LDL cholesterol levels and the ratio of LDL/HDL cholesterol.[16] LDL cholesterol (OR; 1,325, 95% CI; 1,046-1,821, P=0.033) and HDL cholesterol (OR; 0.093, 95% CI; 0.038-0,227, P<0.001) are predictors of carotid plaques.[16]Other studies show that there is no correlation between blood fat levels and CIMT[2]which is in line with this study.

Obese adolescents had thicker CIMT (0.69 mm) than normal adolescents (0.38 mm).[17] The higher of BMI, the greater the thickness of CIMT.[18] There is a positive correlation between CIMT and body fat most commonly found in children with visceral obesity.[13]There was no association between visceral obesity as indicated by waist circumference with CIMT in this study which is in line with the study conducted by Song et al.[19]

The relationship between blood fat levels and CIMT is still controversial. High level of triglyceride associated with the development of atherosclerosis, but the mechanism is unclear. CIMT is inversely proportional to triglyceride levels.[7)]

Studies show the relationship of the risk of cardiovascular disease is higher in girls than boys,[20, 21)] which is consistent with this study where hsCRP had a positive correlation with the left common carotid artery diameter (r=0.533;P=0.004 dan r=0.452;P=0.018). The common carotid artery diameter equation = 5.045 + 0.001 x hsCRP in girls. This correlation were not found in boys.

The diameter of the common carotid artery had a positive correlation with hsCRP (r = 0.284; p = 0.029). In girls, hsCRP had a positive correlation with the diameter of the left common carotid artery (r = 0.533; P=0.004 and r = 0.452; P=0.018) with the syninial common carotid artery diameter equation = 5.045 + 0.001 x hsCRP, but not found in boys.

Conclusion

There was no correlation between TNF-α, hCRP and lipid profile with CIMT.

Survey on Health Indicators of Selected Rural Area of Chhattisgarh

Rohisha I. K.[1], Ritika Rocque[2], Harish Kumar[2]

[1]Tutor, Community Health Nursing, College of Nursing, [2]Tutor, College of Nursing, All India Institute of Medical Sciences Raipur Chhattisgarh

Abstract

According to WHO more than half of world's population lives in villages and rural areas. It is a challenging for the health care workers to protect and improve the health in rural areas[1]. Health of an individual or a community depends on many determinants and survey of any area will help to identify the socio demographic characteristics of particular region and to find the disparities in health services[1]. A survey done among 58 families which included 466 samples was conducted in Jheet village of Durg district of Chhattisgarh to identify the socio demographic characteristics and health condition with an aim to understand the health issues and factors affecting the health. This will help the health workers to plan health promotion strategies in future. The data was collected using a structured Questionnaire. The results of the demographic characteristics showed that majority (53%) of the samples are males and majority (95%) are Hindu families. 72% of the families are of joint type and 25% are of nuclear type. 75% of the population is married and 74% are engaged in private occupation. Results of housing standards showed that 49% of the families are residing in pucca house, 32% are in semipucca houses and 19% in kachha houses. Majority (97%) of families are using dumping as method of waste disposal. Description of special groups showed that samples consisted of 43% eligible couple, 30% target couples, 14% postnatal women, 11% antenatal women and 2% infertile couple. The vital events occurred in the community in one year were 17 births and 2 deaths. Survey on prevalence of disease conditions among 94 samples, Majority were having hypertension (30%) and diabetes (18%), anemia (12%) and psychiatric illness (6%). The major substance abuse present among the samples was alcoholism and pan chewing (24%).

Keywords: *Rural survey, Jheet village, Socio Demographic characteristics, Health Indicators.*

Introduction

Health of an individual or a community depends on many determinants which include environmental conditions, life style, income, safe water supply, sanitation and available health services. The health problems of each community should be identified to provide need based care to the community. Survey of any area will help to identify the socio demographic characteristics of particular region and to find the disparities in health services[1].

According to WHO more than half of world's population lives in villages and rural areas. They are facing many issues which directly or indirectly affect their healthy living and meeting basic living standards. It is a challenging for the health care workers to protect and improve the health in rural areas[1].

India is the 2nd populous country in the world and has changing patterns of health problems, needs, policies and system which is drawing global attention. Many governmental programmes and initiatives are present

which is applied mainly in the rural and backward community but still there is a matter of health concern which is to be addressed among those populations. Socio economic condition, beliefs, customs and environmental conditions create challenges for health sector in improving the health condition of the vulnerable population. The health issues to be addressed according to the felt needs. A survey on health indicators helps to understand the present scenario and plan future activities for improving health and reframing the socio economic structure and living condition of the rural community[2].

Health indicators are the measurement which reflects the current situation. The health indicators not only merely help to observe and document but to drive decision making in health and reduce disparities[3]. This survey was conducted to analyze the socio economic factors and health status of the rural population of Jheet village, Durg district of Chhattisgarh. The aim of the study was to address the disparities in socio economic condition and health status which will help the health workers to plan health promotion strategies in future according to the need of the people of the particular area and improve their living condition. The objectives of the study were to study the demographic conditions of sample population in the study area, to analyze the socio economic condition among sample population in the study area and to investigate the prevalence of health problems among sample population in the study unit.

Material and Method

This quantitative study adopted a descriptive approach to identify the health indicators of the samples of selected rural population and the design used was descriptive survey design. The survey was done among 58 families which constituted 466 samples. The data was collected using structured survey questionnaire which included questions regarding socio demographic characteristics, environmental condition, vital statistics and health status. Interview method was used to collect the data by doing house to house visit. The questions were read by the researchers and responses were marked. The data regarding family condition like housing standard, waste disposal, religion, vital events was collected from the head of the family and data regarding age, occupation, marital status and health status was collected from samples.

Findings: The results of the survey are organized under following headings:

1. **Demographic characteristics among samples of rural area:** The demographic characteristics like age, gender, marital status and religion were analyzed using percentage distribution and shown in figure 1.

n=466

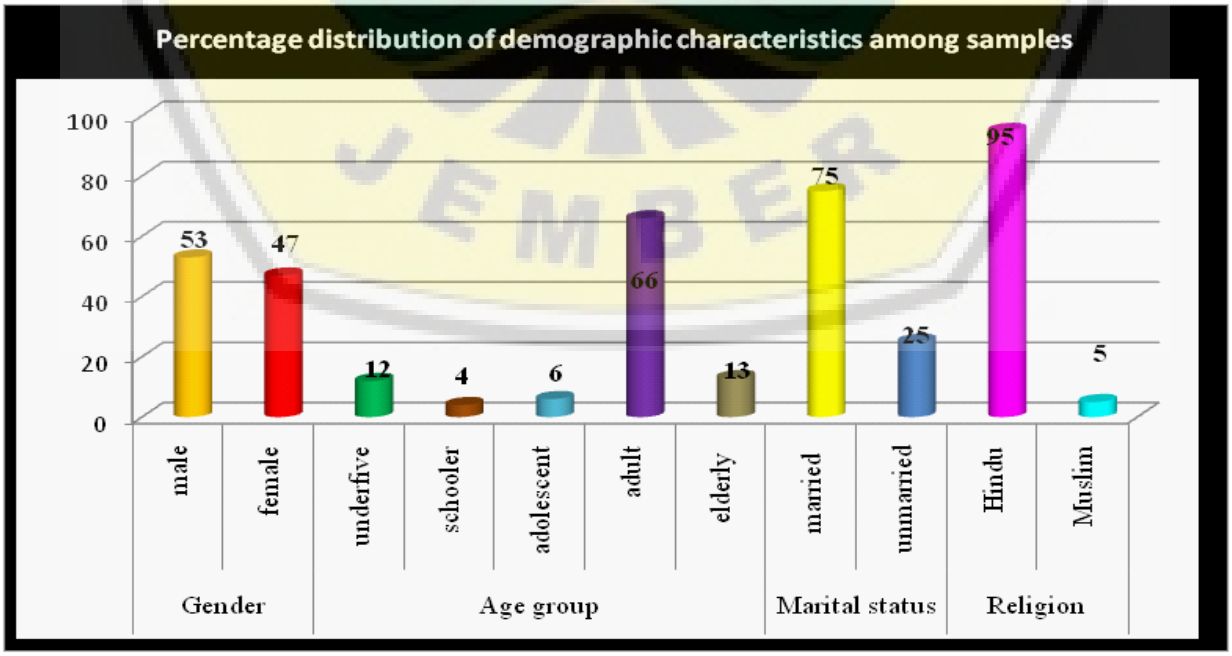

Figure 1: Percentage distribution of demographic characteristics among samples of rural area

Figure 1 shows that majority of the samples are males and married. Most of them belong to Hindu family. The sample consisted 66% of adult population, 13% of geriatric population, 12% of under five children and 6% of adolescents. The results conclude that health services should focus on reproductive age group and on family welfare services. More emphasis should be given on care of under five children and health measures for elderly population. The focus on these areas will improve the health status and living standards of rural population.

2. **Socio economic characteristics among samples of rural area:** The socio economic characteristics was analyzed among 58 families like housing, type of family, waste disposal method,occupation and reproductive health was analyzed among 466 samples using percentage distribution and shown in figure 2 and figure 3.

n=58

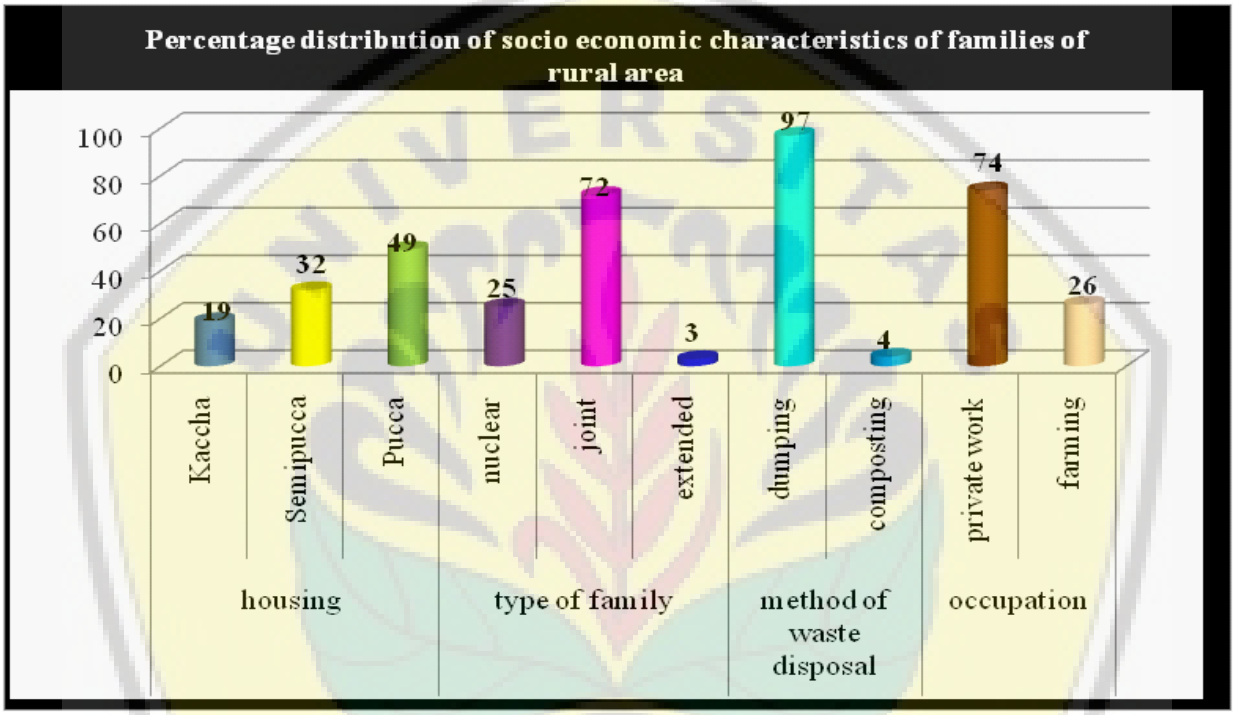

Figure 2: Percentage distribution of socio economic characteristics among samples of rural area

n=63

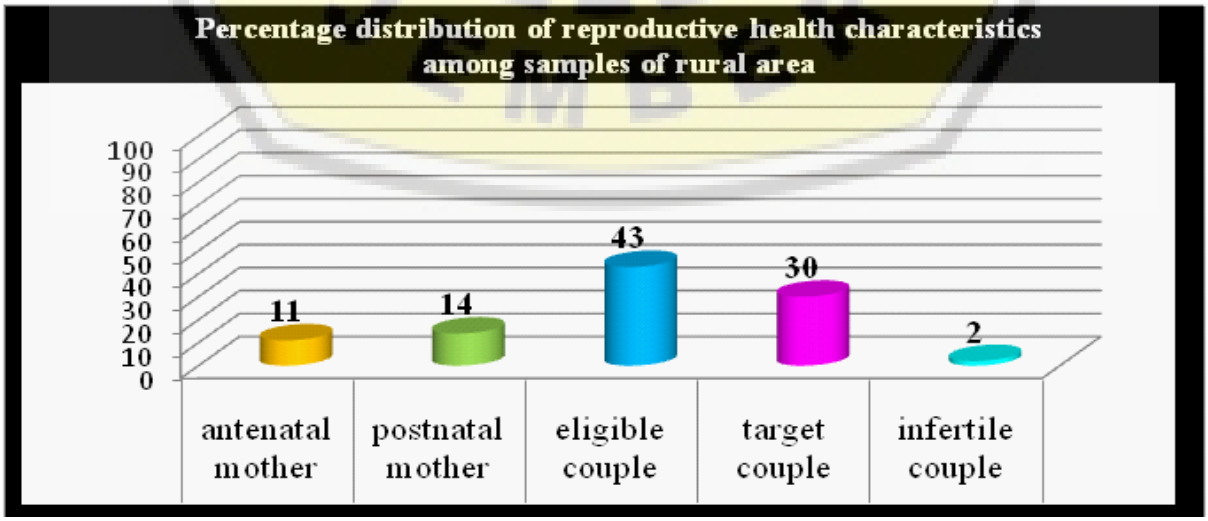

Figure 3: Percentage distribution of reproductive health among samples of rural area

Figure 2 shows that 19% of families are residing in Kaccha houses and 32% of families are residing in Semi Pucca houses. Most of them (72%) belong to joint family. 97% of the families are using dumping as a method of waste disposal. Majority of the sample (74%) are doing private work and 26% are farmers. The results concluded that housing standards and waste disposal method should be addressed which will contribute to the health status of the population. The government initiatives for improving housing standards and developing compositing method for waste disposalshould be implemented more effectively in the rural areas. Figure 3 shows that 43% eligible couples and 30% target couples are present in the selected rural area. Infertile couple consists of 2% of the samples. It is concluded that family planning measures and welfare services should be addressed among the population to improve the standard of living.

3. **Prevalence of health problems among sample population in the study unit:** The prevalence of health problemswas analyzed among the samples and computed using percentage distribution as shown in figure 4.

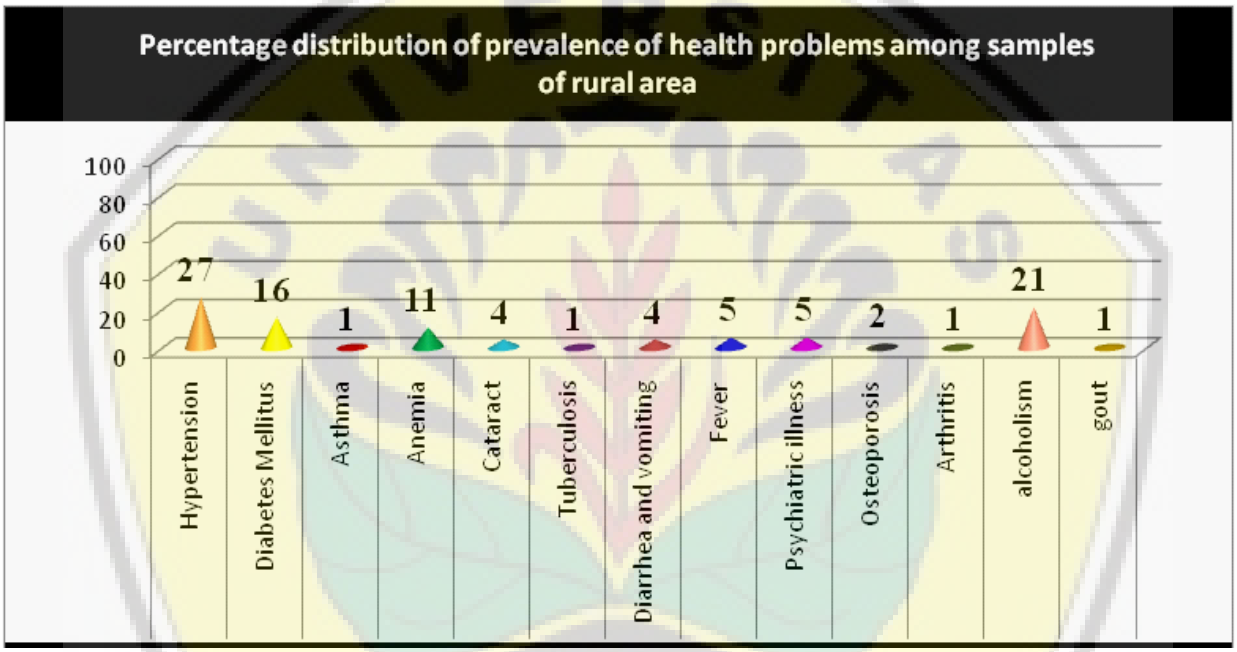

Figure 3: Percentage distribution of prevalence of health problems among samples of rural area

Figure 3 shows that major health problems present in the community were hypertension (27%) and alcoholism (21%). Diabetes mellitus (16%) and anemia (11%) are also present in the community which is to be addressed. The other health problems found among samples are asthma, cataract, psychiatric illness, orthopedic health problems, fever, diarrhea, vomiting and tuberculosis. The results concluded that health education and awareness programmes to be conducted on prevention of non communicable disease programmes and motivate public health workers to strengthen non communicable disease prevention programmes. Rehabilitation programmes should also be initiated to reduce the impact of health problems on community.

Conclusion

The slogan "Health for all" to be attained to provide minimum standard of living to all people in the country. Primary care is the most basic and, along with emergency and public health services, the most vital service needed in rural communities[4]. Primary health care are given importance to deliver the need based health care services to the rural population. There are many factors which hinder delivery of quality care to the rural population. Demographic characteristics, Socio economic factors and reproductive health factors as mentioned in the article will pave light to the current scenario and make the providers aware about the areas where the programmes

to be concentrated. Many other factors like literacy rate, income, mortality rate etc also can be explored further to add clarity to the survey. Local rural healthcare systems are fragile; when one facility closes or a provider leaves, it can impact care and access across the community. Each care provider should ensure that better health care services are reaching the hands of the rural people which will have an impact on the development of the country[4].

Prevalence of Temporomandibular Joint Dysfunction in Hearing and Speech Impaired Adolescents

Romita R. Shah[1], Sayali Gijare[2], Mandar Malawade[3]

[1]Final Year BPTh Student, [2]Assistant Professor, Department of Pediatric Physiotherapy, Krishna College of Physiotherapy, KIMS 'Deemed to be' University, Karad-415110, Maharashtra, India

Abstract

Objectives: Objective of this study was to find out the degree of mouth opening, right and left lateral excursion. On the basis of numerical pain rating scale pain assessment was done. The severity was graded on the basis of fonseca's questionnaire.

Methodology: There were total 94 subjects, out of which 70 subjects were participates of this study. This was a study of temporomandibular joint dysfunction in hearing and speech imapired adolescents. Here we evaluated degree of mouth opening, right and left lateral excursion, pain present or absent and graded them on the basis of Fonseca's questionnaire.

Result: There is relation between Temporomandibular joint dysfunction and hearing and speech imapired adolescents. Temporomandibular joint dysfunction is found more within the age group of 16-18 years as compared to 12-15 years.

Conclusion: There is prevalence of temporomandibular joint dysfunction in hearing and speech imapired adolescents.

Keywords: *Hearing and speech imapired adolescents, temporomandibular joint dysfunction.*

Introduction

The temperomandibular joint is a synovial joint, in which articular disc helps to perform hinge and sliding movements. Chewing, swallowing and talking, are normal mouth functions performed by temporomandibular joint.[1] Osteokinematic and arthokinematic movements are required for normal function of temporomandibular joint. Mandibular depression, elevation, protrusion, retrusion and left and right excursions are the movements which are included in osteokinematic, while rolling; anterior glide, distraction and lateral glide are included in arthrokinematic.[2] Movement at this joint are produced by the muscles of mastication and the hyoid muscles. The two division of the temporomandibular joint have different functions.

Protusion: Lateral pterygoid muscle assisted by medial pterygoid and

Retraction: Posterior fibers of temporalis.

Elevation: temporalis, masseter and medial pterygoid muscles.

Depression: Digastric, geniohyoid and mylohyoid muscles.

Pain in the masticatory muscles and at the joint is referred as joint disorder or dysfunction which is the most common pathology related to temporomandibular joint.[9]

e-mail: mandarmalawade@gmail.com

Signs and symptoms of joint dysfunction:

- pain in the area of jaw
- oedema around the mandibular condyle
- increased or decreased active or passive range of motion
- popping or clicking sound
- catching or locking of jaw
- forward head posture[2]

Normal ranges:

Degree of Mouth opening: 50.6 +/- 6.4mm

Right lateral excursion: 10.2 +/- 2.2mm

Left lateral excursion: 10.6+/- 2.3mm

According to the reports, it is most common in women.[14] According to epidemiological studies, approximately 50-75% of population presented with some signs of joint dysfunction.[13] It has multifactorial etiology.[3] Combination of muscle tension, anatomical problems and injury is the most often cause of temporomandibular joint dysfunction [8] Also, there are other risk factors which causes injuries to temporomandibular joint resulting in joint derangement, joint degeneration, masticatory muscle dysfunction, pain and progressive clinical disability.[4]

Around 466 million people worldwide have disabling hearing loss and 34 million of these are children. [5] 63 million people are suffering from significant hearing loss in India.[12]

Deafness refers to the complete loss of hearing ability in one or two ears. Hearing impairment refers to the complete or partial loss of the ability to hear from one or both ears. Hearing loss can be conductive, sensorineural or mixed type and can be congenital or acquired. Majority of deaf individual do not use spoken language, thus they are mute. Deaf mute individuals are those people who are deaf and use sign language or both deaf and could not speak. True communication is in which one understands the message by others and respond in same manner[16].

Two conditions may result muteness:

1. Physical muteness is in which individual has problem in throat or vocal cords and cannot speak.
2. In deaf individual they can make sound but cannot speak because they cannot hear.[16]

Appropriate communication and learning, are the basic necessity for the normal development and maturation of the child which is limited in hearing and speech impaired individuals..[10] Hearing loss before the age of 2-3 years is the one of the causative factor which affects the child's ability to learn how to speak. An individual who is congenitally deaf is also the possible causative factor.[11] For the development of speech in an individual, listening is the essential component. Our spoken tone, pitch and rhythm are modulated with the help of our ears. Speech impairments are often developed in people who experience hearing loss and may stop to speak entirely.[6] The main impact of hearing loss is the individual's ability to verbally communicate with others and the way left to communicate is sign language and writing for communication and interaction.[17] There is very limited verbal interaction, if any. This in return limits the activity of jaw. This may lead to change in range of motion of temporomandibular joint. But there is very limited literature available which shows the co-relation of hearing loss and its impact on communication. So this study is aimed to find out the possibility of signs and symptoms of temporomandibular joint dysfunction and its relation with the hearing loss.

Methodology

Total 94 subjects were approached through DS Erram hearing and speech imapired school and out of them only 70 subjects were selected for the study who fulfilled inclusion criteria. There were 42 male and 28 female participants. The procedure was explained and consent was taken from those willing to participate and written assent was taken from caregivers. Here we evaluated their degree of mouth opening, right and left lateral excursion, pain present or absent and graded them on the basis of fonseca's questionnaire. Range of right and left lateral excursion and also degree of mouth opening was recorded by using vernier caliper. Pain was assessd on rest and activity by using Numerical Pain Rating scale. They were graded according to their signs and symptoms based on Fonseca's Questionnaire. Data was collected. Later statistical analysis was done in accordance to distribution of the age, both genders, score of Fonseca's Questionnaire, right and left lateral excursion, degree of mouth opening, pain at rest and pain on activity.

Result

1. Age and gender wise distribution:

Table No. 1: Age and gender wise distribution.

Serial No.	Age Group	Subjects	Gender	
			Male	Female
1	12-15	42	27	15
2	16-18	28	15	13
Total		**70**	**42**	**28**

Interpretation: Above table represents, in age group 12-15 years there are total 42 subjects out of which 27 are males and 15 are females and in age group 16-18 years, there are total 28 subjects out of which 15 are males and 13 are females.

2. Results of Numerical Pain Rating Scale (NPRS):

Sr No	Pain		P value		T value		Interference	
	Rest	Activity	Rest	Activity	Rest	Activity	Rest	Activity
1	0.142±0.3914	0.623±1.436	<0.0001	<0.0001	3.054	3.605	Very significant	Extremely significant

Table No. 2: Pain at rest and Pain on activity

Interpretation: Above table represents Pain at rest mean and and SD value is 0.142±0.3914, p value is <0.0001 and t value is 3.054. pain on activity mean and SD value is 0.623±1.436, p value is <0.0001 and t value is 3.605.

3. Degrees of mouth opening:

Table No. 3: Degree of mouth opening, Right lateral excursion and Left lateral excursion.

Sr. No.	Range of motion	Normal	Decreased	Mean ± SD
1.	Mouth opening	47	23	44.042 ± 5.752
2.	Right lateral excursion	60	10	9.258 ±1.451
3.	Left lateral excursion	61	9	9.374 ± 1.472

Interpretation: Above table represents 67% (47 subjects) of subjects have normal range of mouth opening and 33%(23 subjects) of subjects have decreased degree of mouth opening. Mean and standard deviation is 44.042 ± 5.752. In right lateral excursion, 86%(60 subjects) of subjects have normal range and remaining 14%(10 subjects) of subjects have decreased range and mean and SD is 9.258 ±1.451. in left lateral excursion 87%(61 subjects) of subjects have normal range and 13%(9 subjects) of subjects have decreased range and mean and SD is 9.374 ± 1.472.

4. Scoring of Fonseca's Questionnaire

Table No. 4: Scoring of Fonseca's Questionnaire

Serial No.	Score of Fonseca's Questionnaire			Mean±SD
1	No TMD	Mild TMD	Moderate TMD	16.57±14.977
2	47	18	5	

Interpretation: Above table represents, Score of Fonseca's Questionnaire, 47 subjects have no temporomandibular joint dysfunction, 18 subjects have mild temporomandibular joint dysfunction and remaining 5 subjects have moderate temporomandibular joint dysfunction.

5. Prevalence of temporomandibular joint dysfunction:

Table No. 5: Prevalence of temporomandibular dysfunction.

Serial No.	Prevalence	
1	Absence of TMD dysfunction	Presence of TMD dysfunction
2	47	23

Interpretation: Out of 100%, 33% (23 subjects) of subjects have temporomandibular dysfunction and remaining 67% (47 subjects) of subjects have no temporomandibular dysfunction.

Discussion

Temporomandibular joint carries out various functions like chewing, swallowing, talking, etc. Appropraite communication and learning is the basic necessity for normal development and maturation of child, which is limited in hearing and speech imapired individuals.

For the development of speech, listening is an important component which is impaired in deaf individuals. Ear helps to modulate our spoken tone, rhythm and pitch. Hearing and speech impaired individuals use sign language for communication. There is very limited verbal interaction, if any. This in return may limit the acitivity of jaw. This may lead to change in range of motion temporomandibular joint.

The purpose of this study it was to find out the prevalence of temporomandibular joint dysfuncytion in hearing and speech impaired adolescents.

The study was carried out and the result was drawn by fonseca's questionnaire, vernier caliper and NPRS.

Total 94 subjects were approached out of which 70 subjects were included in study who fulfilled the inclusion criteria (female- 28 and male- 42) and age group 12-18 years .The subjects were taken from DS Erram hearing and speech impaired school. This age group included individuals diagnosed as hearing and speech impaired individuals and both male and female participants were included. They all didn't have any ear infection, any recent temporomandibular joint surgery and also recent trauma. Consent form was taken from the subjects and assent form from their caretakers.

It was found that among 70 subjects, 60% subjects belonged to 16-18 years of age group and remaining 40% belonged to 12-15 years of age group. In age group 12-15 years, there were total 42 subjects out of which 27 were males and 15 were females. In age group 16-18 years, total 28 subjects were there out of which 15 were males and 13 were females.

Pain was assessed using numerical pain rating scale. Among 70 subjects, 87% of subjects had no pain at rest and 13% of subjects had mild pain at rest but no one had moderate and severe pain in the basis of numerical pain rating scale.

80% of subject had no pain on activity, 13% of subjects had mild pain on activity and remaining 7% had moderate pain on activity, but no one had severe pain on activity.

Range of motion was assesd with the help of vernier caliper and according to the result it was found that 14% of subjects had decreased range of right lateral excursion and 86% of subjects had normal range of right lateral excursion.

Out of 100%, 13% of subjects had decreased range of left lateral excursion and 87% of subjects had normal range.

Among 100%, 67% had normal degree of mouth opening and 33% had decreased degree of mouth opening.

According to Fonseca's Questionnaire scoring, 71% of subjects showed no signs and symptoms of temporomandibular joint dysfunction, 21% of subjects showed mild symptoms of temporomandibular joint dysfunction and 2% of subjects showed moderate symptoms. In age group 12-15 years, 39 subjects had no symptoms of TMD, 3 had mild symptoms of TMD and no one had moderate and severe symptoms. Out of 3 subjects, 2 were females and one was male. In age group 16-18 years, 8 subjects had no symptoms of TMD, 15 had mild symptoms of TMD and 5 had moderate symptoms of TMD. Out of 15 subjects with mild symptoms, 10 were famales and 5 males. Out of 5

subjects with moderate symptoms 3 were females and 2 males..

Out of 70 subjects, 47 subjects had no signs and symptoms of temporomandibular joint dysfunction, 18 subjects had mild signs and symptoms of temporomandibular joint dysfunction and remaining 5 subjects had moderate signs and symptoms of temporomandibular joint dysfunction. Prevalence of 33% of temporomandibular joint dysfunction in hearing and speech impaired adolescents was present.

Conclusion

On the basis of the results of the study, it can be concluded that there is prevalence of 33% Temporomandibular joint dysfunction in hearing and speech imapired adolescents. Temporomandibular joint dysfunction is found more within the age group 16-18 years as compared to 12-15 years. In age group 12-15 years of age, 13% subjects had symptoms of temporomandibular joint dysfunction and in age group 16-18 years of age 87% had symptoms of temporomandibular joint dysfunction.

Abstract

Smoking behavior mostly occur in adolescence which is characterized by increased frequency and intensity of smoking. Smoking can cause various diseases and deaths. There are internal factors and external factors that influence smoking behavior. The study aims to determine the influence of adults, peers, advertisements and curiosity motive and the psychological impact on adolescents in Tinggede Village, Sigi Regency. This study uses a mix method research type. The sample size and informants involved were 46 respondents and 6 informants. Quantitative research data were analyzed univariat using the chi-square test. The results showed there was a relationship between the influence of parents (ρ = 0.039), peers (ρ = 0.039) and curiosity motive (ρ = 0.018) with adolescent smoking behavior and there was no relationship between advertisement and adolescent smoking behavior (ρ = 0.238). As well as the perceived psychological impact of informants feeling more confident, feeling calm and feeling fine. The conclusion of this study is that there is a relationship between the influence of adults andpeers and motive of curiosity with adolescent smoking behavior and there is no relationship between advertisement and the smoking behavior and psychological impact on adolescents in Tinggede Village, Marawola District, Sigi Regency. It is recommended for adolescents to be able to be selective in facing the influence of adults, peers and positive or negative advertisements in everyday life.

Keywords: *Smoking, adolescent, impact, psychological.*

Introduction

The increasing prevalence of smoking causes the problem of smoking to become increasingly serious. According to the WHO(1), the number of world smokers reached 1.35 billion people. About 1 billion men in the world are smokers, 35% of them are from developed countries and 50% from developing countries. On the average of 435,000 residents in the United States have died from diseases related to smoking habits each year (1 of 5 deaths).

Based on 2008 Global Youth Tobacco Survey (GYTS) data, 30.1% of the population of Southeast Asia are smokers. In Indonesia, 57,563,866 adult residents are smokers, making it the fifth highest cigarette consumer country in the world[1].

According to WHO[1], it can be concluded that Indonesia ranks third after China and India in the ten largest smokers in the world. The number of smokers in Indonesia reaches 65 million. Meanwhile, China has 390 million smokers and India 144 million smokers. Tobacco kills more than 5 million people every year and in 2020, it is projected to reach 10 million people.

The data from the Health Promotion Technical Implementation Unit of the Central Sulawesi Provincial Health Office, it is known that there are 172 (57.14%) households that smoke in Palu City from the 301 monitored households. In 2012, 63.34% of them smoked.

Then, it increased in 2013 as many as 57.14% of them smoked[2].

Smoking is a health problem because it can cause various diseases and even death. Smoking is a major factor in cardiovascular disease and hypertension. Cigarettes contain hundreds of chemical components that are toxic and oxidative. Smoking habits allow toxic substances in cigarettes to accumulate in the blood, one of which is nicotine[3].

Based on the results of Basic Health Research in 2010, most smokers started smoking when they were children or adolescents. Adolescence is a period of transition from childhood to adulthood and at this age, teenagers or adolescents do a lot of smoking behavior. Smoking behavior in adolescents continues in accordance with the stages of development that will increase which is marked by increasing frequency and intensity of smoking[4]. Smoking habits in adolescents are influenced by several factors such as adults, peers, personality and information media that display cigarette advertisements[5].

Method

The type of research used was quantitative research with a cross sectional study approach, conducted in September 2015. The research was conducted in Tingggede Village, Marawola District, Sigi Regency. The population of the study was 83 adolescents and there were 46 respondents taken as samples with Simple Random Sampling technique.

Data Collection: The research data used are primary data and secondary data. The primary data were obtained from the results of observations and interviews with adolescent smokers. The process of data collection is done by using a questionnaire to describe the variables studied. While the secondary data was obtained from the Office of the Village Head of Tingggede, Marawola District, Sigi Regency, in the form of data on the number of teenagers. The variables in this study consist of dependent variables and independent variables. The dependent variable is smoking behavior in adolescents. While the independent variables include the influence of adults, peers, the influence of advertisements and the motives of curiosity. After data collection was done, the data was processed and analyzed. Then, the results of the analysis were presented in the form of a frequency distribution table that explains everything related to this research.

Results

The Factor of Smoking Behavior: Table 1 showed that smoking teenagers who imitate adult smokers are as many as 16 people or 34.8% while those who do not imitate adult smokers are as many as 30 people or 65.2%. Chi Square test results obtained a value of ρ (α (0,000 <0,05) or X2 calculate value (4,261) > X2 table (3,841) so that Ho in this study was rejected, meaning that there is a relationship between the effect of imitating adults and adolescent smoking behavior. This table 1 showed that adolescents who smoke because they imitate their peers are as many as 16 people or 34.8%, while adolescents who do not imitate their peers are 30 people or 65.2%. Chi Square test results obtained a value of ρ ≤ α (0,000 <0,05) or X2 calculate value 4,261) > X2 table (3,841) so that Ho in this study was rejected, meaning that there is a relationship between the effect of imitating peers and adolescent smoking behavior.

Table 1. The Analysis of the Influence of Adults, Peers, Advertisements and Curiosity Motive on Smoking Behavior in Adolescents

Smoking Behavior in Adolescents					
		n	%	X^2	ρvalue
Adults	Yes	16	34,8	4,261	0,039
	No	30	65,2		
Peers	Yes	16	34,8	4,261	0,039
	No	30	65,2		
Advertisements	Yes	19	41,3	1,391	0,238
	No	27	58,7		
Curiosity Motive	Yes	15	32,6	5,565	0,018
	No	31	67,4		

Table 1 shows that there are 19 adolescents or 41.3% who smoke because of the effect of advertisements, while adolescents who smoke not because advertisements are 27 people or 58.7%. Chi Square test results obtained a value of ρ α α (0,000 <0,05) or X2 calculate value (1,391)> X2 table (3,841) so that Ho in this study was accepted, meaning that there is no relationship between the effect of imitating advertising and adolescent smoking behavior. Table 1 shows that adolescents who smoke because of the motive of curiosity are as many as 15 people or 32.6%, while adolescents who smoke not because of the motive of curiosity are as many as 31 people or 67.4%. Chi Square test results obtained a value of ρ α α (0,000 <0,05) or value X2 calculate (0,018)> X2 table (3,841) so that Ho in this study was rejected, meaning that there is a relationship between the effect of curiosity and adolescent smoking behavior.

Discussion

The Relationship of the Effect of Imitating Adults and Adolescent Smoking Behavior: Adults are examples and models for teenagers, but for adults who do not concern the importance of health, they have indirectly taught unhealthy behavior or lifestyle. One reason that makes many adolescents smoke is their parents' poor parenting style, for example, the behavior of parents who smoke and the behavior emulated by their children from generation to generation[6,7]. The results of the analysis show that the value of ρ = 0.039 which means that there is a relationship between imitating adults and adolescent smoking behavior. This can happen because the permissive parenting of parents usually provides very loose supervision. It provides opportunities for children to do things without sufficient supervision. Parents tend not to reprimand or warn their children when they are in danger and very little guidance is given by them. If parents provide good parenting, it is possible for children to follow good behavior from their parents. However, if parents have bad habits or behaviors such as father or mother who also have smoking habits, children will follow the example of their parents' behavior[7]. This study is in accordance with research[8,9], based on the results of the chi-square test, it was obtained ρ = 0.003. This means that there is a relationship between family influence and smoking behavior in adolescents in Slongohimo Wonogiri Public Middle School 1, because the value of ρ <of α or 0.003 <0.05.

The results of this study are in accordance with what was stated by[10]. It is stated that the strongest reason when adolescents become smokers is that if their parents become exemplary figures as smokers. Their children will naturally have a greater chance to imitate and become smokers like them. Parents who smoke will influence their teenagers to smoke more than parents who don't smoke. Adolescents whose both parents and older siblings smoke will be four times more likely to be smokers compared to them whose parents do not smoke.

The Relationship between the Effect of Imitating Peers and Adolescent Smoking Behavior: There are many factors that influence a teenager to smoke, one of which is peer influence. The more a teenager has a smoker friend the more likely he is to smoke.The results of the analysis show that the value of ρ = 0.039 means that there is a relationship between imitating peers and the smoking behavior of adolescents. This can happen because usually peers' conversation, attitudes, interests, appearance and behavior are more influential than parents. This is what is called as conformity. Conformity occurs when adolescents adopt the behavior or attitude of other teenagers or peers because of pressure, either directly or indirectly. Conformity usually causes compliance and obedience. This happens because a teenager wants to maintain his position in the group and he does not want to be considered strange by his friends in his group. Conformity in this case is as a motive for being equal, appropriate, diverse in the group.

This research is similar to research[10,11], based on the results of the chi-Square test, the value of ρ = 0.013 was obtained. It means that there is a relationship between the influence of peers and the smoking behavior of adolescents in Slongohimo Wonogiri 1 Public Middle School, because ρ <of α or 0.013 <0.05. Peers can be interpreted as groups of people who have the same background, age, education and social status and they can usually influence the behavior and beliefs of each member. In addition to the same age level, peers also have the same level of maturity[12].

The Relationships between the Influence of Imitating Advertisements and the Adolescent Smoking Behavior: Advertising is a medium to convey information to public about a product and it has a function to persuade public about cigarette products.The results of the analysis show that the value of ρ = 0.238 which means that there is a relationship between the action of imitating advertisements and smoking behavior of adolescents. This is because cigarette advertising does not stop influencing teenagers to consume cigarettes.

Teenagers cannot avoid the invasion of thousands of advertisements in electronic media and printed media. Mass or electronic media that often display a picture that smokers are the symbol of manliness, triggered teenagers to imitate or follow the behaviors which are performed by the models in the advertisement[13]. This research is similar to Ariani's research (14). Based on the results of the research' data analysis using chi-square, the value of ρ = 0.311 was obtained. This means that there is no relationship between advertising and smoking behavior of Semarang State Senior School 4 students, because ρ <of α or 0.311 <0.05. It also explains that risk factors for the emergence of smoking behavior in adolescents are influenced by several factors, one of which is environmental factors.

The Relationship between the Effect of Curiosity Motive and Adolescent Smoking Behavior: The curiosity motive is a strong desire that emerges from the adolescents to try a new thing that they have not known its positive and negative effects. The results of the analysis show that the value of ρ = 0.018 which means that there is a relationship between the motive of curiosity and the smoking behavior of teenagers. There are several psychological reasons that cause a person to smoke. It is for the sake of relaxation and to reduce anxiety or tension. In most smokers, the psychological bond with cigarettes is due to the need to deal with oneself easily and effectively. Cigarettes are needed as a balance tool. This is the reason that makes teens dare to try smoking. The desire to know and being predictive of the influence of drugs including smoking tend to be the reason for a smoker. Being curious is teenagers' nature. They always want to know everything that they still do not know and its negative effects[15]. This research is similar to Ariani's researh1[3,16]. Based on the results of data analysis using chi-square, the value of ρ = 0,000 was obtained. This means that there is a relationship between the motive to try smoking and smoking behavior in students of Tangerang City Junior High School 3, because ρ <of α or 0,000 <0.05. With the motive of curiosity about smoking behavior, teenagers will start trying and looking for opportunities to smoke. Some teenagers want to try something new. This desire must be controlled by adolescents before knowing what the impact is for themselves and their environment. Teenagers have the nature of always being curious about something they still do not know its negative effect. For example, they want to know how it feels to smoke[16,17,18].

Conclusion The conclusion of this study is that there is no significant relationship between the factors imitating the models in an advertisement and smoking behavior in adolescents. However, there are three factors that have a significant relationship to smoking behavior in adolescents in Tinggede Village, namely the factor of imitating adults, imitating peers and motive of curiosity. Adolescents are expected to be able to increase their knowledge and be able to filter the negative and positive influence of adults, peers and advertisements so that they can be selective and careful in choosing a social environment. There should be parents' attention and control towards the behavior of their children who have started smoking from an early age.

Funding: This research was funded by the Public Health Faculty Tadulako University in fiscal year 2018.

Research Permit: This study did not require ethical clearance because there is no treatment on the respondent. research only equipped with a research permit from the campus (Public Health Faculty Tadulako University) with the number 2712/UN28.1.30/KP/2018.and from the Sigi Regional Goverment.

Abstract

Most of the pre-packaged food products; imported and locally manufactured; are now provided with nutrition information on their food labels. With the rising concerns about the interrelationship between nutrition; health and life style among rural population; this study has aimed to assess the consumer's awareness about the important information on the labels and to whether those labels will assist them to take right decisions when buying pre-packaged foods. Sample size is 155. Self structured study questionnaire is used. Significant correlations were found between single items on the food label and some of the demographic variables; the overall knowledge of the consumers did not show significant correlation with the overall level of education of the consumers in this study. The findings will bring to the attention of pre packaged food manufacturers and regulators on the need to improve food labeling regulations and food label formats and also provide baseline information for further research.

Keywords: *Pre packaged food, food labels, awareness, food labelling regulations.*

Introduction

Liberalization of trade, globalization and development in food science and technology has resulted in an increase in trade and consumption of pre-packaged foods. Reading food labelling information is important in assisting consumers to better understand the nutritional value of food and enables them to compare the nutritional values of similar food products and to make healthy informed food choices based on the relevant nutrition[1].

Consumer's knowledge and attitudes were positively correlated with their educational level[2-3]. It was evident that even though consumers were aware of the importance of reading food labels; they regarded information on manufacturing date; expiry date and content of the package as the most important information on labels[4]. This indicates that other information such as nutrition facts; serving size; special characteristics; health claims; special usage and health warnings are lacking[5].

Low awareness of food labeling, low level of education, low health consciousness, products attributes, food labeling format, influence of media, perceived role of regulatory authorities and non availability of consumer guidelines on the use of food labeling have been reported by studied from various countries as factors related to consumers not reading and using food labeling information in purchasing food[6-8].

Although little is known about the magnitude of the problem in Tamilnadu, studies conducted in other countries show that small proportion of people are reading and using food labeling information in purchasing pre packaged food products[7-9]. This might

unknowingly predispose them into buying expired food items, foods with undesired ingredients and or untoward health consequences.

This study has aimed to assess the consumer's awareness about the important information on the labels and to whether those labels will assist them to take right decisions when buying pre-packaged foods. The information will bring to the attention of policy makers on the need to have programs to improve consumers awareness of food labeling information as well as the use of such information in the purchase of food.

Aim: The aim is to determine the knowledge, attitude and practices towards food labeling among the adults in an urban area.

Objective:

- To evaluate the knowledge, attitude and practices towards food labeling among the consumers of food labeling.
- To determine the importance of food labelling information among consumers

Materials and Method

Type of study: Descriptive epidemiological - community based cross sectional study.

Study population: Adult inhabitants in an urban area.

Study area: Anna nagar, metropolitan city in Chennai.

Study period: April 2017 to June 2017

Sample size: 155 calculated with non response rate of 10%.[10]

Study subject: Head of household

Sampling technique: Systematic random sampling technique used.

Selection Criteria:

1. **Inclusion Criteria:**
   - The participant should be resident of the study area
   - Those who give informed consent
2. **Exclusion Criteria:**
   - Those not willing to participate in the study
   - Those who could not communicate
   - Any person who could not be contacted even after 3 visits
   - Those with any acute or chronic illness will be excluded from the study

Data collection procedure and Instruments used: The study after obtaining clearance from the IRB of SIMATS. Information sheet with pertinent information was given to all the participants invited to participate in the study. Written informed consent was obtained from all participants of the study.

A pilot study conducted in the study area for a sample of 30 people. Suitable modifications were made. After selecting the study population, the purpose of the study were explained to the individuals. Following the data collection, analysis was done.Every fourth house was selected and interviewed.

Tools: A self structured questionnaire used

Statistical analysis: Data will be entered in Microsoft excel and data analysis was done using SPSS 16. Association with various factors were analyzed using chi square test. Statistical significance is considered to be 5 % level.

Findings: A total of 158 respondents participated in the study. Males constituted 88 (55.99%) of all respondents. Large proportion of respondents (43.6%) was in the age group 40-49 while the smallest proportion (3.7%) was in the age group 60 and above. Most of the respondents 111 (70.25%) had socioeconomic status has upper middle class.

As shown in figure 1, more than 50% respondents said that the source of food is from provisional stores and supermarket. About 79% of population reported that they buy the packaged foods.

All the study respondents 158 (100%) were aware of food labelling. But only 48 (30.38%) of study subjects claimed to be very much informed about food labelling information.

There is no statistical significance between level of information about food labelling and demographic characteristics (M/F) .(Analysis table 1)

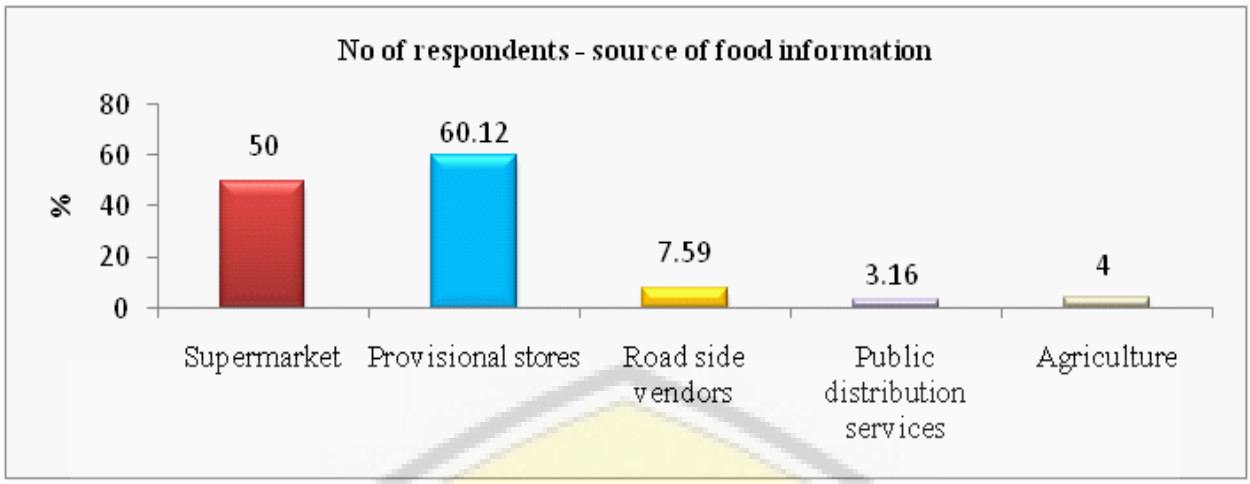

Figure 1

58.22% of respondents said that they know about food labelling through media and least is from retailers (5.69).

More than 70% respondents were well familiar with expiry date (97.46), manufacture date(86.70%), nutritional value (72%), instruction for use (80.37%), Price (94.30), Trade mark (88.60) and Name of manufacture (74%).87.97% respondents were satisfied with the information provided but knowledge of existing matters need to be developed, while 2% respondents needs much more information than existing.

In this survey, only 34.81% heard of food labelling information scheme. More than 70% have knowledge about trademarks which is the agmark standard (84.17%), ISI mark (97.46%), vegetarian mark (70.25%). Only 9.49% of population know about codex alimentarius, which is the principle organ of joint FAO/WHO food standards programme. 89% of respondents aware of the fact that the prices labelled on the packages are inclusive of all taxes.

Table 1: Knowledge towards food labelling

Sr.No.	Question	Response
1.	Do you know about food labeling?	Yes 100%
2.	How well are you informed about food labeling information?	Very much informed 30.38%
		Moderately informed 55.69%
		Minimally informed 55.69%
		Not informed 3.79%
3.	What made you know about food labeling?	Media – TV, newspaper, advertisements etc 58.22%
		Friends 19.62%
		Family members 27.84%
		Doctors, nutritionist etc 8.86%
		Awareness programme 8.22%
		Books and magazine 21.51%
		Internet 8.86%
		Retailers 5.69%

Sr.No.	Question	Response
4.	Which of the following terms are you most familiar with in relation to the basic information found on pre-packaged food labels?	Expiry date 97.46%
		Manufacture date 86.70%
		List of ingredients 79.11%
		Method of storage 71.51%
		Nutritional value 72.15%
		Net content 27.84%
		Instructions for use 80.37%
		Price 94.30%
		Trade mark 88.60%
		Name of manufacturer 74.05%
		Country of origin 53.16%
		Batch or lot of identification 29.11%
5.	Is the information provided is satisfying?	Yes 87.97%
6.	Food labeling should be	i. Enforcedly provided under legislation 85.44%
		ii. Voluntarily provided by manufacturers/producers 85.44%
		iii. Standardized and applied to all food products 94.30%
7.	Have you heard of the food labeling information scheme?	Yes 34.81%
8.	Do you know about agmark standards?	Yes 84.17%
9.	Do you know about ISI mark?	Yes 97.46%
10.	Do you know about vegetarian mark?	Yes 70.25%
11.	Do you know about CODEX ALIMENTARIUS, which is the principle organ of the joint FAO/WHO food standards programme?	Yes 9.49%
12.	Are you aware of the fact that the prices labeled on the packages are inclusive of al, taxes?	Yes 89.87%

97.47% of respondents said that they read food labelling information before purchasing pre packaged foods and when they were enquired about the frequency, 101 respondents (63.92%) read food labels always and only 6.32% read food labels rarely. There is statistically significant association that presence of children is positively affecting consumers when making decisions on food purchase as they read more the food labels. Families with children are keener to read food labels. (Analysis table 2).

76% of population first seek expiry date before deciding to purchase or eat a particular food and they don't care much about batch or lot of identification, net content, method of storage and instructions for use. There is significant association between gender and looking for special characteristics. This indicates awareness of people giving importance to special characteristics. (Analysis Table 3). There is no significant association between socioeconomic status and seeing expiry date and special characteristics (Analysis table 5). Though the knowledge about trade mark is more than 70%, the practice of seeing agmark, ISI, vegetarian mark is only around 50%.

Table 2: Practices towards food labelling

Question	Response
1. Do you read food labeling information before purchasing pre packaged foods?	Yes 100%
2. If yes, how frequently do you read food labels when you first purchase a prepackaged food product?	Never 3.79%
	Rarely 6.32%
	Sometimes 12.02%
	Often 10.75%
	Always 63.92%
	When not in hurry 3.16%
3. What information do you first seek on food label before deciding to purchase or eat a particular food?	Expiry date 76.58%
	Manufacture date 10.12%
	List of ingredients 1.89%
	Method of storage 0 .63%
	Nutritional value 1.89%
	Net content 0.63%
	Instructions for use 0.63%
	Price 22.78%
	Trade mark 2.53%
	Name of manufacturer 3.16%
	Country of origin 1.89%
	Batch or lot of identification 0.63%
4. Do you see the agmark standard before you buy food?	Yes 57.59%
5. Do you see ISI mark before you purchase food?	Yes 70.25%
6. Do you see the vegetarian mark before you purchase the food?	Yes 56.32%

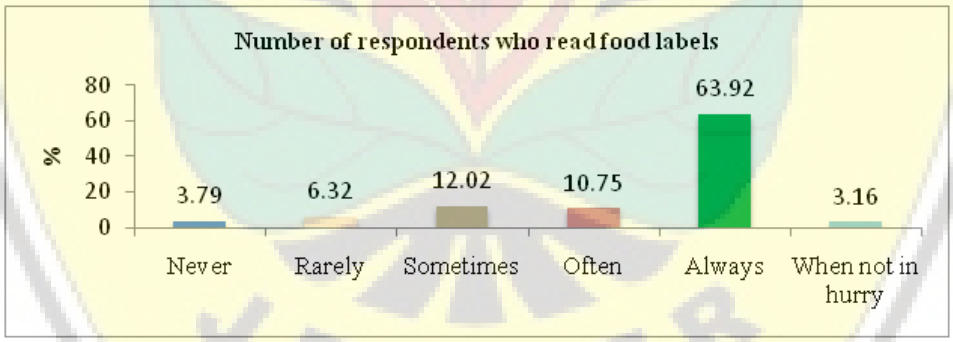

Figure 2

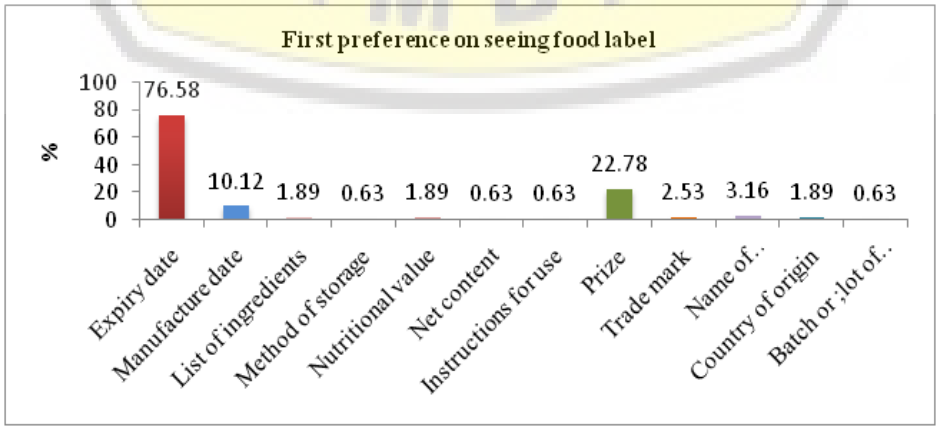

Figure 3

Among the 158 respondents, 144 people agreed that reading the food nutrition labels can help them make informed food choices.

75% of study subjects willing to pay a higher price for any product or service provided they get value for their money and they think that information needed to become a well informed consumer are readily available and 24.68% were not willing to pay higher price for a good quality product.

Of the study subjects, 24.48% were not aware of their consumer rights. 78% think that manufacturers make efforts to design and develop products to suit to the need of the consumer and 21.15% said that they are not making genuine efforts to suit.

There is no significant association between age group and media mislead (Analysis table 4)

If some important information are not available in the label, 22.15% of population would still buy the same.

Table 3: Attitude questions

Question	Response Yes	Percentage
1. Do you think the information provided is satisfying for you?	137	86.70%
2. Do you agree that reading the food nutrition labels can help you make informed food choices?	144	91.13%
3. Are you willing to pay a higher price for any product or service provided you get value for your money?	119	75.31%
4. Do you think the information needed to become a well informed consumer are readily available?	119	75.31%
5. Do you think that you are aware of your rights?	113	71.51%
6. Do you think that manufacturers make efforts to design and develop products to suit to the need of the consumer?	124	78.48%
7. Do you think that advertisements mislead your informed food choices?	127	80.37%
8. Do you think manufactures are responsible for any complaints of consumers?	135	85.44%
9. If some important information are no available in the label, would you still buy the same?	35	22.15%
10. Would you look for details of label for all types of packed foods?	130	82.27%

Table 4: Consumers perception and factors associated with reading food labels

Question	Response
1. How important do you consider food labeling information to be?	Very important 82.27%
	Somewhat important 14.55%
	Minimally important 1.89%
	Not important 1.26%
2. What motivates you to read labeling information?	Price of the food 48.73%
	Appearance/design of the package 17.08%
	Preference to some ingredients 36.70%
	Advertisements 14.55%
	Friends 6.32%
	Family 10.12%
3. In which circumstances do you buy pre packaged foods without reading labeling information?	When food is sold at a low price 6.32%
	When in a hurry 46.20%
	On street/journey 8.86%
	Trust on the seller 32.91%
	No circumstances like that 20.25%

Question	Response
4. What difficulties do you come across in reading and understanding pre packaged food labels?	Unfamiliar language 10.12%
	Use of technical/scientific terms 34.81%
	Incomplete labelling 15.82%
	Smaller font size 50%
	No difficulties 9.49%
5. How useful is it?	Very useful 98.73%
	Not useful 1.26%

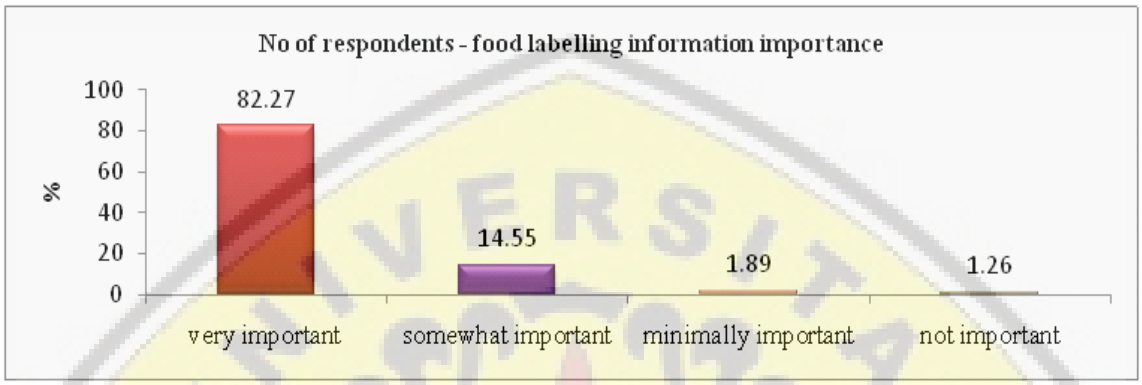

Figure 4

CHI Square Test:

Table 1: Analysis

Sex	Verymuch Informed about Food Labeling	Not Informed about Food Labelling	Total	χ^2 test
Male	74	14	88	0.8525 (NS)
Female	62	8	70	
Total	136	22	158	

NS–Not significant

There is no significant association between information about food labelling and gender at p> 0.05 level.

Table 2: Analysis

Children	Always Read Food Labels	Rarely Read Food Labels	Total	χ^2 test
Yes	81	35	116	6.9101**
No	20	22	42	
Total	101	57	158	

** P <0.01

There is significant association and we conclude that presence of children is positively affecting consumers when making decisions on food purchase as they read more the food lables. Families with children are keen to read food labels.

Table 3: Analysis

Sex	Expiry Date	Special Characteristics	Total	χ^2 test
Male	70	18	88	8.0637**
Female	67	3	70	
Total	137	21	158	

**p<0.01

There is significant association between gender and looking for special characteristics. This indicates awareness of people giving importance to special characteristics p< 0.01 level

Table 4: Analysis

Age Group	Media Misleading	Media Not Misleading	Total	χ^2 test 0.1651(NS)
Less Than 40 Years	52	12	64	
More Than 40 Years	75	19	94	
Total	127	31	158	

NS – Not significant

There is no significant association between age group and media influence on selecting food information at p> 0.05 level.

Table 5: Analysis

Socio Economic Status	Expiry Date	Special Characteristics	Total	χ^2 test 0.5525 (NS)
Upper Class	35	6	41	
Middle Class	102	15	117	
Total	137	21	158	

NS – Not significant

There is no significant association between socio economic status and food labelling seeking characteristics p> 0.05 level.

Conclusion

The study determined to assess the consumers' knowledge; attitude and practices towards food labeling in an urban area and the information they would like to see on the food label for the first time in Tamilnadu. Although significant correlations were found between single items on the food label and some of the demographic variables; the overall knowledge of the consumers did not show significant correlation with the overall level of education of the consumers in this study. The most frequently referred labelling information that consumer try to seek are expiry date, list of ingredients and nutrient information. The findings also revealed that lots of food label information were known to people by mass media which shows the lack of dissemination of correct information by health care workers. There were circumstances in which consumers did not read food labels because they purchased routine familiar foods or foods was sold at a lower price.

Hence; the study recommends further studies on the consumer's ability to make use of the labelled information. As well, an evaluation for the existing nutrition awareness programs and specifying needs for extension programs in nutrition and food label are also needed.

Nasal Versus Oral Feeding Tube Placement: Selected Outcomes among Preterm Infants

Salwa M. Ahmed[1], Hanan M. Rashad[2], Hoda A. Mahmoud[3], Tamer A. Abd El Hamid[4]

[1]Clinical instructor, [2]Assistant Professor, [3]Lecturer, Pediatric Nursing, Pediatric Nursing Department, Faculty of Nursing, Cairo-University, [4]Assistant Professor, Pediatric Medicine, Pediatric Medicine Department, Faculty of Medicine, Cairo-University.

Abstract

Background: Enteral feeding tubes for preterm infants may be placed via either the nose or mouth. Nasal tube placement may compromise respiration, however, orally placed tubes may be more prone to displacement. The aim of the current study was to determine the effect of nasal versus oral placement of enteral feeding tubes on weight and the incidence of adverse events among preterm infants. Method: A descriptive comparative study design was utilized.

Sample: A convenient sample of sixty physiologically stable preterm were assigned to two equal groups within six months (between July 2018 – Jan. 2019). They were recruited from neonatal intensive care units of both Kasr Alainy and El-Monira Pediatric Hospitals-Cairo University.

Tools: Three tools were developed by the researchers: preterm infant's characteristics, observational checklist for incidence of adverse events and recording sheet for daily weight and time to sustain full oral feeding. Procedure: The researches recorded preterm infant's characteristics, any adverse events, weight and time to sustain full oral feeding in the morning shift twice a week for two weeks.

Results: Orogastric tube feeding was statistically significant different compared to nasogastric tube feeding regarding displacement. There was no difference among two groups in weight gain, time to reach full feeds and frequency of adverse events. Orogastric tube feeding group had lesser duration of hospital stay than nasogastric and orogastric tube feeding group reached to full oral feeds quickly compared to nasogastric with no statistical significant differences. Recommendation: Further researches with a larger population would probably be required to know the significance of this outcome.

Conclusion: This study concluded that no differences were found between both orogastric and nasogastric tube feeding on preterm infants' weight, incidence of adverse events and time to sustain full oral feeding.

Keywords: *Nasogastric tube, orogastric tube, Preterm Infants,outcomes.*

Introduction

When preterm infants are too immature or unwell to suck feeds they can receive their milk through a feeding tube passed via either the nose or the mouth. The establishment of safe oral feeding in preterm infants may be delayed because of poor co-ordination of sucking and swallowing, neurological immaturity and respiratory compromise. Enteral feeds may be delivered through a catheter (feeding tube) passed via the nose or via the mouth into the stomach or upper small intestine(1).

Neonates are obligate nose breathers. Feeding tubes placed via the nose can cause partial nasal obstruction, increased airway resistance and increased work of breathing(2,3). This increase in energy expenditure may potentially affect growth and development. Nasogastric intubation through the larger nare may increase airway resistance as the preterm infant is forced to breathe through an airway of smaller calibre. In addition, individual differences in nasal size may be acquired secondary to the effects of nasogastric tubes(4).

Incorrect placement, or subsequent displacement, of feeding tubes into the lower oesophagus or into the lung can lead to aspiration, respiratory compromise and increased energy expenditure[5]. Orally placed tubes may be easier to displace as they can loop inside the mouth. Repetitive movement of the orally placed tube may result in mucosal trauma and may increase the incidence of apnea and bradycardia due to vagal stimulation [6]. There is not enough data to make any recommendation regarding the superiority of either routes of feeding [7].

Aim of the study: To determine the effect of nasal versus oral placement of enteral feeding tubes on weight and the incidence of adverse events among preterm infants.

Research question: What are the differences between nasal and oral placement of feeding tube on weight and the incidence of adverse events among preterm infants?

Material and Method

Research Design: A descriptive comparative study design was utilized.

Participants: A convenient sample of 60 preterm infants were assigned to two equal groups within six months (between July 2018 – Jan. 2019).

Tools of Data Collection: Three tools were developed by the researchers after extensive review of related literature: preterm infant's characteristics, observational checklist and recording sheet for weight and time to sustain full oral feeding.

Tool Validity and Reliability: Data collection tools were submitted to three panel of experts in the field of high risk neonates to test the content validity. Reliability was done by cronbqch's alpha test and the result was 0.82.

Procedure: After the preterm infants had initial physiological stable state, they assigned to receive either nasogastric or orogastric feeding, the researchers' recorded preterm infant's characteristics once from admission sheet using tool I. They assessedany adverse events such as apnea, displacement and injury (trauma) in the morning shift twice a week for two weeks using tool II. All infants were weighed each morning, naked, before feeding and bathing, on one same time and time to sustain full oral feeding was recorded for all preterm infants using tool III.

Results

Table (1) Characteristics of Preterm Infant's Characteristics For Both Groups In Percentage Distribution (N=60).

It was evident from table (1) that there were no statistically significant differences between orogastric and nasogastric groups regarding their gender, diagnosis and gestational age ($p > 0.05$).

Preterm Infant's Characteristics	Groups				P
	Orogastric (n=30)		Nasogastric (n=30)		
	N	%	N	%	
Gender:					
- Male	17	56.7	13	43.3	0.219
- Female	13	43.3	17	56.7	
Diagnosis:					
- RDS	27	90	25	83.3	0.729
- M.A	3	10	3	10	
- Sepsis	-	-	2	6.7	
G.A.					
- <32 Weeks	9	30	13	43.3	0.284
- 32-37 Weeks	21	70	17	56.7	

Note: RDS = Respiratory distress syndrome, M.A = Meconium Aspiration, C.S = Cesarean Section NVD = Normal Vaginal Delivery, G.A: Gestational Age

It was revealed from table (2) that there were no statistically significant differences between orogastric and nasogastric groups regarding their hospital stay ($p > 0.05$).

Table (2): Hospital Stay For Both Groups In Percentage Distribution (N=60)

Hospital Stay:	Groups				P
	Orogastric (n=30)		Nasogastric (n=30)		
	N	%	N	%	
- One-<two weeks	1	3.3	-	-	0.346
- Two-<three weeks	6	20	3	10	
- Three-<four weeks	2	6.7	5	16.7	
- Four weeks and more	21	70	22	73.3	
Mean±SD	41.27±18.984		41.47±17.190		

It was illustrated from table (3) that there were no statistically significant differences between both groups regarding their daily weight at the four measures.

Table (3): Daily Weight at 1st, 2nd, 3rd and 4th Measures in Percentage Distribution (N=60).

Daily Weight	Groups		P
	Orogastric	Nasogastric	
	Mean±SD	Mean±SD	
1st Measure	1699.17±340.018	1606.50±354.951	0.190
2nd Measure	1693.83±332.586	1621.33±357.247	0.598
3rd Measure	1724.00±329.897	1693.00±351.027	0.211
4th Measure	1740.00±327.246	1712.00±337.062	0.270

It was represented from table (4) that there was no statistically significant difference about time to sustain full oral feeding for both groups ($p > 0.05$).

Table (4): Time To Sustain Full Oral Feeding For Both Groups At 1st, 2nd, 3rd and 4th Measures In Percentage Distribution (N=60)

Time to sustain full oral feeding	Groups				P
	Orogastric		Nasogastric		
	N	%	N	%	
-< a week	2	6.7	4	13.3	0.287
-Week-<two weeks	11	36.7	9	30	
-Two weeks-<three weeks	4	13.3	2	6.7	
-Three weeks-<four weeks	3	10	7	23.3	
-Four weeks and more	10	33.3	8	26.7	

Discussion

There was limited data available on the effect of the nasal versus the oral route for placing feeding tubes in preterm or low birth weight infants.

In relation to preterm infant's characteristics. The current study revealed that more than half of the preterm infants were males in the orogastric group, while more than half were females in nasogastric group. This findings goes in the same line with[8], who reported that more than half of preterm infants in both orogastric and nasogastric groups were males. While[9] contradicted these findings and reported that more than half of nasogastric group were males, while in orogastric group, a relatively high percentage of preterm infants were females.

The result of the current study revealed that more than three quarters of preterm infants were diagnosed with RDS in both groups. This study goes in the same line with [10], who found that more than two thirds of neonates had RDS.

Regarding gestational age[8] who studied Mode of gavage feeding: does it really matters, reported that the

highest percentage of preterm infants in both orogastric and nasogastric groups their gestational age were ≥30 - <32 weeks and this contradicted with the result of the current study which revealed that more than two thirds of orogastric group and more than half of nasogastric group preterm infants were born between 32-37 weeks of gestation with no statistically significant differences of both groups.

Hospital stay was slightly longer in nasogastric group than orogastric group but with no statistically significant differences among both groups, as mean duration of hospital stay was 41.47 days in orogastric group and 41.47 days among nasogastric group. This result contradicted with the study of (9). Who revealed that there was no much difference among two groups. Mean Duration of hospital stay was 35.38 days with standard deviation of 7.60 among Nasogastric tube feeding group and 37.54 days with standard deviation of 9.45 among Orogastric tube feeding group.

Preterm infants in orogastric group gained weight more than those in nasogastric group at 1st, 2nd measures, 3rd and 4th measures. As mean of weight were (1699.17, 1693.83, 1724.00 and 1740 respectively) in orogastric group and (1606.50, 1621.33, 1693.00 and 1712.00 respectively) in nasogastric group but there was no statistically significant differences. This findings supported by(9), who demonstrated that mean time to regain birth weight was 19.38 days among Nasogastric tube feeding group and 19.23 days among Orogastric tube feeding group. Also (11), who studied continuous feeding promotes gastrointestinal tolerance and growth in very low birth weight infants, reported no statistically significant difference in the time taken to regain birth weight.

Regarding adverse events of both orogastric and nasogastric tube placement, the results of the current study delineated that, there was no statistically significant differences between both orogastric and nasogastric groups about injury at the 1st, 2nd, 3rd and 4th measure. This findings supported by(9), who concluded that there were no significant differences among two groups to frequency of adverse effects.

Concerning displacement, the current study illustrated that there was statistically significant difference between both orogastric and nasogastric groups at the 2nd measure (p= 0.050), while there were no statistically significant differences between both groups about displacement of the feeding tube at the 1st, 3rd and 4th measures. This findings supported by(8) who reported that the episodes of non-intentional removal and displacement are more in OGT group and it statistically significant (p = 0.012 and p<0.0001 respectively). Also(9), reported that frequency of tube displacement was more common among Orogastric tube feeding compared to Nasogastric tube feeding. Which was statistically significant with a p-value of 0.001, mean difference of -0.4462 times/day.

In the matter of apnea, the results of the current study showed that there were no statistically significant differences between both orogastric and nasogastric groups about episodes of apnea at the 1st, 2nd, 3rd and 4th measures. This findings goes in the same line with(8), who reported that episodes of apnea, bradycardia, desaturation and oxygen requirement are more in NGT group as compared to OGT group but statistically Insignificant OGT versus NGT (p = 0.86).

For time to sustain full oral feeding, the highest percentage of both orogastric and nasogastric groups reach to full oral feeding by one week to less than two weeks from starting oral feeding. There were no statistically significant differences about time to sustain full oral feeding for both orogastric and nasogastric groups. This finding was in agreement with (8) who found that orogastric tube group neonates required (6.18±0.61) days as compared to Nasogastric tube group neonates as they required (6.47±0.59) days to achieve full feeding but it is statistically insignificant (P =0 .368).

Based on clinical observation. The differences between both groups in terms of outcome measures like duration of hospital stay, time to reach oral feeds were not statistically significant which may be due to small sample size and there is need of larger samples and also further continuation of this study to know the significance of these outcomes.

Conclusion

This study concluded that no differences were found between both orogastric and nasogastric tube feeding on preterm infants' weight, incidence of adverse events and time to sustain full oral feeding.

Ethical Clearance: Acceptance of ethical committee at faculty of nursing, in Cairo University was gained. All studied neonates' parents were informed about the aim, procedure, benefits and nature of the

study and the written consent was obtained from them. The confidentiality of information was assured.

Conflict of Interest: the authors declare that there is no conflict of interest.

Source of Funding: There are no resources of fund.

Effect of Abdominal Massage on Uterine Involution

Sandhya Kumari R. Rajbhar[1], Anjali Tiwari[2]

[1]M.Sc. Nursing, [2]Assistant Professor & HOD, Dept. of Obstetrics & Gynaecological Nursing, Manikaka Topawala Institute of Nursing, Charotar University of Science & Technology, Gujarat, India

Abstract

Pregnancy & becoming a mother is a great experience for women but at the same time it may be a terrible experience if complicated. The common complication that occur after delivery are mostly due to causes like a tonic uterus, retained lobe of placenta, sepsis, subinvolution, etc. This study was done to evaluate effect of abdominal massage on uterine involution among postnatal mothers. A quasi experimental design was selected where 70 samples were recruited using convenient sampling technique & then randomly allocated to experimental and control group (35 in each). After the pre-intervention assessment, abdominal massage was given to the participants of experimental group only. After 3 days of intervention, post-intervention assessment was done for both the groups. Wilcoxon signed rank test was used to evaluate effect of abdominal massage. The study concluded that abdominal massage was significantly effective in accelerating the rate of uterine involution among postnatal mothers.

Keywords: *Abdominal massage, Uterine involution & Postnatal mothers.*

Introduction

In every woman's life, pregnancy is a unique, great, unforgettable experience & an exciting time. This experience of woman helps cultivate the essence of future.[1] Puerperium is a duration starting from third stage of labour to the six weeks after delivery. The physical and physiological changes that had occurred during the pregnancy, will revert back to non pregnant state within this duration.[2]

Involution is a normal process after end of third stage of labour, in which uterus begin to shrink and within some day's duration become like a nonpregnant state. Subinvolution of uterus is common cause that arises further complications among postnatal mothers, in which, impairment occurs in the rate of involution. If the uterus fails to revert back to its pre-pregnant state after delivery then it may result in long-lasting & disturbing complications like extreme continuous vaginal bleeding, uterine cramping & pungent uterine discharge.[3]

WHO states that majority of maternal death in developing countries are preventable with aid of good, advance medical facility and awareness.

Fundal massage is a conservative technique which can help to reduce bleeding & cramping immediately after delivery.[4] Studies show that postnatally problems like uterine pain, subinvolution, atony can be managed by application of abdominal massage.

India still being a developing nation may not be able to provide access to all the areas a well maintained medical facility with modern equipments.[5] Hence in such case we may use basic conservative measures to bring about positive change in the health of the women. Fundal massage is one such measure which has found to be effective in various postnatal ailments but still not much study have been done on its efficacy on uterine involution in Gujarat & India. Hence the researcher felt the need to take up this study.

Material and Method

A Quasi-experimental research design was adopted for present study. Ethical clearance and formal permissions were obtained to conduct the study. 70 samples were conveniently recruited from selected hospitals of Central Gujarat & then were randomly allocated to experimental and control group (35 in each). Participants who had undergone a cesarean section or had an instrumental delivery were excluded from the study. A researcher developed Performa was used to collect baseline information of the participants where as a measure tape was used to assess the uterine involution in terms of fundal height. Pre-intervention assessment was done on day 1 for both the groups. Along with routine care, abdominal massage was provided to the participants of experimental group for 10 minutes, 2 times a day (morning & evening) for 3 consecutive days. Whereas the control group received only the routine care post-intervention assessment was followed after these 3 days.

Result

Finding related to socio-demographic and maternal variables of postnatal mothers of both the groups showed that majority of the participants in experimental group 57.1% & control group 31.4% belonged to 23-27 year age group where as 54.3% & 57.1% of them had completed primary education respectively. 40% and 25.7% participants in experimental & control group respectively were second para. 60% in experimental and 71.4% in control group participants were non vegetarian. In experimental group 62.9% as well as in control group 45.7%, participants were having height between 151 to 160 cm. 57.1% of experimental group and 37.1% of control group participant weight range was between 51kg-60kg.14.3% and 11.4% participants of experimental and control group respectively had a past history of abortion.

Finding related to effectiveness of abdominal massage on uterine height among postnatal mothers of experimental and control group: Comparison of effect of abdominal massage on uterine involution of both the groups was done using Wilcoxon Signed Rank test. The calculated Z value for day 1 morning, day 1 evening, day 2 morning, day 2 evening, day 3 morning and day 3 evening was 10.4 ($p<0.000$), 9.7 ($p<0.000$), 8.8 ($p<0.000$), 7.2 ($p<0.000$), 0.4 ($p=0.684$) and 0.5 ($p=0.560$) respectively. This data indicated that on initial 2 days there is highly significant effect of abdominal massage on uterine involution with p value less than 0.000. Hence the research hypothesis that there is statistically significant effect of abdominal massage on uterine involution at 0.05 level of significance stands accepted.

Findings related to association between pre-intervention uterine heights of postnatal mother with their selected socio-demographical & maternal variables.

Table No. 1: Spearman's Rho correlation coefficient was used to determine the associations

Spearman's rho		
Socio demographic & Maternal variables	**Correlation Coefficient (r)**	**P Value**
Age in years	.315	.008
Level of Education	.031	.796
Type of physical activity at job/Occupation	-.281	.019
Type of Family	-.047	.701
Number of Pregnancy	.221	.066
Diet	-.057	.641
Height	.265	.027
Weight in Kilogram	.430	817.100
History of Abortion	-.150	.215
Area of living	-.136	.262
Day1 Before intervention (Morning-Evening)	1.000	

The data in table show that variables which include age, type of physical activity at job/Occupation and height had a significant correlation coefficient with p value less than 0.05. Level of education, type of family, number of pregnancy, diet, history of abortion and area of living had no significant correlation ($p>0.05$). Hence the hypothesis, that there is statistically significant association between pre-intervention uterine height with the selected socio-demographical and maternal variables at 0.05 level of significance, stands accepted.

Conclusion and Recommendations

The study concluded that abdominal massage was effective in accelerating the rate of uterine involution among postnatal mothers. Hence, it can be used as a non-pharmacological method to prevent uterine subinvolution.

This type of study can be conducted on large samples to make broad generalization, can be undertaken at different setting. Similar study can be done in combination of other non-pharmacological method related to uterine involution as well as Comparative study can be done to evaluate effect of abdominal massage with other non-pharmacological intervention for accelerating uterine involution. Thus a simple measure of abdominal massage can be effectively used in a developing country, not only to accelerate the rate of uterine involution but also to prevent many maternal complications and help in making the postnatal period more joyful for the mother.

Effect of Sensory Motor Integration Technique on Motor Dysfunction in Guillain-Barre Syndrome.

Sanket R. Thorat[1], G. Varadhrajulu[2], Suraj B. Kanase[3]

[1]Intern, [2]Dean, [3]Associate Professor, Department of Neurosciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Background: Guillian-Barre syndrome (GBS) is an autoimmune disorder that affects motor as well as sensory nerves. There is rapidly progressing muscle weakness typically pyramidal in distribution. Autonomic nervous system is also involved in this condition. The recovery is slow thus physical therapy along with medical management plays an important role. Sensory motor integration is a relationship between various sensory inputs to produce desired motor response.

Objectives: Objectives of the study were to determine the effect of Sensory Motor Integration Technique On Motor Dysfunction in GBS and to reduce the recovery time.

Material and Method: In this experimental study, 28 subjects with GBS were assessed with GBS disability scale and subjects were given Sensory Motor Integration Technique along with medical treatment and other therapies.

Results: Statistical analysis was done of GBS disability scalein 28 subjects in which it was seen that post treatment there was very significant effect of Sensory Integration Technique. (p value- 0.002)

Conclusion: The current study concluded that there is a significant effect ofSensory Motor Integration Technique On Motor Dysfunction in Guillain-Barre Syndrome. There was significant decrease in disability in GBS patients after the intervention thus Alternate Hypothesis accepted.

Keywords: *GBS, Sensory Motor Integration, Physical Therapy, GBS disability scale, Disability.*

Introduction

Guillian-Barre syndrome (GBS) is an autoimmune disorder which involves peripheral nervous system and is acute in onset.[1] GBS is rapidly progressing motor disorder associated with absent reflexes.[2] GBS varies in severity and in its severest form, could lead to respiratory paralysis and death.[3] Acute inflammatory demyelinating polyradiculoneuropathy (AIDP) is the most common type of GBS which primarily causes demyelination with varing degrees of secondary axonal damage. Acute motor axonal neuropathy (AMAN) is the next most common type of GBS which is primary considered as axonal disorder affecting just the motor nerves and causing motor symptoms.[4] Axonal variants that involve both sensory and motor symptoms are not seen much.[4]

It has shown that, with age, incidence of GBS could be more frequent and it is predominantly most common in males but some literature suggest that it is common in females.[2,5]

GBS is caused due to a viral or an bacterial infection, may be precipitated by a vaccination, could be caused

e-mail: drsurajkanase7@rediffmail.com

after a major surgery due to several reasons or caused by prolonged use of several drugs such as zimelidine.[5] Studies have shown that *Campylobacter jejuni*, Epstein Bar virus, Mycoplasma pneumonia and Cytomegalovirus are the most frequent causative factors.[2,5]

The onset of the disease starts with sensory symptoms in the distal extremities followed by rapidly progressive distal weakness that spreads proximally.[2] The weakness seen GBS is typically pyramidal in distribution, for example, ankle dorsiflexion and knee and hip flexion are often severely affected and the weakness in the arms is usually more severe in shoulder abduction and elbow extension.[2] Sensory symptoms commonly seen although minor and include loss of vibration and proprioception. Symptoms such as areflexia, myalgia, sphincter disturbances and autonomic disturbances are commonly seen in GBS.[5]

GBS is a monophasic disease. The neuropathy typically begins 7–10 days after any triggering infection with weakness reaching its most severity in 4 weeks followed by a plateau phase and then followed by a recovery phase. 60% of patients are able to walk unaided by 12 months and the some patients are have various degrees of residual symptoms.[6] Mortality rate in GBS is between 5 and 10 percent and the major causes of death include infection, emboli and autonomic instability.[2,7]

GBS is medically managed by plasmaphereis, steroid therapy and IgG [5] but supportive management has been more effective in improving mortality in patients with GBS with good ICU care and modern method of ventilation. Passive movement of the extremities and active physiotherapy including chest physiotherapy once the initial acute stage commences, is seen to very beneficial.[2] Since much of the damage to nerves occurs early in the course of the disease it may be more effective to look at treatments capable of improving nerve regrowth and regeneration with medical drugs as well as newer physiotherapy management approaches. Increased knowledge of GBS and its pathophysiology may form a base for new, targeted and personalized treatments that hopefully will improve the outcome for the patients.[8]

Katz defines sensory integration as "an innate neurobiological process in which the brain integrates and interprets sensory stimuli in the environment"[9]

Sensory integration (SI) is the ability to organize sensory information to make an adaptive response.[10] Sensory input from the environment and from the body provides information to the brain. The brain then organizes, integrates, synthesizes and processes this information to obtain appropriate response to stimuli. The processing of information allows individuals to receive sensory inputs and respond automatically, efficiently and comfortably to it.[10]

There exists a relationship between motor responses, sensory input and normal sensorimotor development which will be helpful for providing a treatment approach in GBS patients.

It has been noted that sensory system has facilitatory or inhibitory influences on the motor systems. Motor system needs inputs from various sensory systems. Research shows that, sensory integration techniques stimulates cutaneous sensations, proprioceptors, visual component to produce the desired motor response.

Aim and Objectives:

Aim: To find the effect of Sensory Motor Integration Technique On Motor Dysfunction in Guillain-Barre Syndrome.

Objectives:

- To determine Effect of Sensory Motor Integration Technique On Motor Dysfunction in Guillain-Barre Syndrome.
- To reduce the recovery time and make patient ambulatory while studying the effect of sensory motor integration technique along with other therapies given.

Materials and Methodology

- **Type of study**- Experimental study
- **Study Design-**Pre-test and post test
- **Place of Study-**Krishna hospital, Karad
- **Sample formula –** $n= 4 X SD^2/(X€)^2$
- **Sample size-** supposed to be 30
- **Sampling Method-**Consecutive sampling
- **Study duration-** 6 months

Materials Required:

- GBS disability scale.

Selection Criteria:

Inclusion Criteria:

- Both Male and Female
- Have neurological impairment secondary to GBS
- Unable to ambulate more than 200 feet without assistive devices
- Able and willing to comply with the protocol

Exclusion Criteria:

- Recent of History of seizures
- Evidence of upper motor neuron involvement
- Any medical condition, including psychiatric disease, which would interfere with the interpretation of the study monitors.
- Clinically diagnosed diabetic neuropathic individuals.

Outcome measures: Gullian Barre Syndrome Disability scale

Procedure: Individuals with GBS were selected on basis of inclusion and exclusion criteria. Informed consent was taken from the patients. Subjects were assessed before starting with the protocol. Subjects will be explained about the procedure of the study.

- Subjects were selected through consecutive sampling.
- Pre test assessement was taken using GBS disability scale.
- Exercise session were given for 30-45 minwith rest intervals for 4 days/week for a duration of 8-10 weeks.
- Sensory Motor Integration techniques were given to these patients which included vestibular based activities including swiss ball and wobble board exercises along with assisstance, proprioception exercises that included weight bearing with the help of closed kinematic chain exercises such as mini squats by holding the bar with assisstance and wall pushups, stretching of major muscle groups was also done, tactile stimulaton included prehension by holding objects with different surface designs such as soft ball and asking the patient to feel the pressure and use of ADL table, co ordination activities included throwing the ball, catching the ball, hitting the ball, etc and cobmination of all these exercises were given to the patient along with visual and auditory cues.
- After the intended duration of treatment the efficacy of the treatment protocol in both the groups were compared.
- Post test assessment was taken after 4 weeks by using GBS disability scale.
- Pre-test and Post-test, the data collection sheets were filled and assessed.
- Statistical analysis was done using appropriate biostatistical tools.

Findings:

Table 1: Age Distribution

Study Variables	N	Minimum	Maximum	Mean	Std. Deviation
Age (in Years)	28	18	40	29.71	6.26

Interpretation: Table 1 represent quantitative study variables distribution among study population. Here minimum age of participants was 18 years and maximum age of was 40 years, also average age of 29.71±6.26.

Table 2: Gender Wise Distribution of Study Population.

Gender	Frequency	Percent
M	15	54%
F	13	46%
Total	**28**	**100%**

Interpretation: Out of 28(100%) study participants 15(54%) were males and 13(46%) were females. [Seen in Table 2]

Table 3: Gullian Barre Syndrome Disability scale

Sr.No.	Parameter	Pre-test	Post-test	t value	p value	Inference
1.	GBS Disability Scale	3.10±1.13	2.07±1.27	3.213	<0.002	Very Significant

Result

Within the group statistical analysis (Table 3) shows that there was significant decrease in GBS diability after the intervention. The mean pre intervention was 3.10 ± 1.13 which significantly decreased to 2.07± 1.27 post intervention.

Discussion

This study was conducted to study the effect of Sensory Motor Integration Technique on Motor Dysfunction In Guillain-Barre Syndrome. Guillian-Barre syndrome (GBS) is an rapidly progressing autoimmune motor disorder which is acute in onset and which involves involvement of peripheral nervous system. GBS varies in its severity, there are patients with mild to moderate residual symptoms and in its severest form, it could lead to respiratory paralysis and death.[3] Griffin JW et al. suggests that there are various types of GBS including acute motor axonal neuropathy (AMAN) which is one of the most common type of GBS-primary considered as axonal disorder affecting just the motor nerves and causing motor symptoms.[4] The treatment approaches used in this study will be more beneficial to such patients. However the incidence of GBS is 1 in 100,000, thus due to the limitations faced this study focuses on GBS as a broad terminology and includes patients diagnosed with GBS as a diagnosis. The causative factors of GBS in these patients were not known but some presented a history of previous infection.

The onset of the disease starts with sensory symptoms in the distal extremities followed by rapidly progressive distal weakness that spreads proximally. Winer JB states that the weakness seen GBS is typically pyramidal in distribution. Ankle dorsiflexion and knee and hip flexion are often severely affected and the weakness in the arms is usually more severe in shoulder abduction and elbow extension. This in turn affect the balance, posture and gait in these patients leading to no or less motor control required for activities of daily living. Sensory symptoms commonly seen include loss of vibration and proprioception which play an important role in coordination and activation of neuromuscular system. Symptoms such as areflexia, myalgia, sphincter disturbances and autonomic disturbances were also seen in severe cases of GBS.[5]

Winer JB also suggests that 60% of patients are able to walk unaided by 12 months and the some patients are have various degrees of residual symptoms.[6] The objective of this study was to enhance the recovery with less time and make patient ambulatory with sensory motor integration along with other therapies employed.

Ayres studied the relationship between motor responses, sensory input and normal sensorimotor development. She defined sensory integration (SI) as the ability to organize sensory information to make an adaptive response. Sensory integration (SI) is a term that states combination of various sensory inputs to get the desired motor response.[5] Katz defines sensory integration as “an innate neurobiological process in which the brain integrates and interprets sensory stimuli in the environment”[9]

The main aim of this study was to see the effectiveness of sensory motor integration technique on motor dysfunction in Guillain-Barre Syndrome. Objectives of the study were to determine the effect of sensory motor integration technique on motor dysfunction in guillain-barre syndrome and to reduce the recovery time and make patient ambulatory with sensory motor integration technique along with other therapies already given.

30 individuals were selected over a period of 6 months and they participated in the study out of which all individuals fulfilled the selection criteria but 28 individuals continued their participation in the study for 8 weeks. Subjects were screened by Gullian Barre Syndrome disability scale pre-test. Out of 28 individuals 15 were males and 13 were females. Male predominance was seen. A study titled “Population incidence of

Guillain-Barré syndrome: a systematic review and meta-analysis, " by J. J. Sejvar et al. supports this difference noted, by suggesting that GBS is more common in male population.[11]

Treatment included vestibular based activities which were carried out with movable surfaces like swiss ball or tilt board activities to stimulate the patient affected with GBS and improve their righting reactions, equilibrium and autonomic responses. These exercises helped in improving balance, postural control, muscle tone and co activation of different muscle groups. They also promoted self control and security with movement.[5] Also tactile based activities helped to facilitate body image awareness and included deep or light pressure input and self controlled tactile stimulation by prehension exercises and use of objects with various surface modifications. Various weight bearing activities such as CKC exercises which included mini squats and wall pushups followed by stretching of major muscle groups stimulated proprioception and improved co activation of muscle groups and body perception. Co-ordination activities included kicking the ball, catching ball, hitting a ball with a plastic bat and writing etc which incorporated timing of responses, pairing of vision with motor outcomes as well as muscle activation patterns also improved. All sensory integration techniques were combined and incorporated and the desired results were obtained.[5] Task related training plays an important role in improving lower limb control which in turn enhances walking performances[12].

The treatment sessions were carried out for 4 days per week for 8 weeks. Post 8 weeks Gullian Barre Syndrome disability scale was again assessed among the subjects. Outcome measures showed significant difference among disability status. This was confirmed using statistical analysis by using 'Paired t- test' for within group comparison.

Within the group comparison, the Gullian Barre Syndrome disability status pre treatment was 3.10±1.13 which changed to 2.07±1.27 (P value <0.0002)considered very significant which showed small but significant improvement in GBS patients. According to mean GBS disability score, pre intervention the patients were able to walk 10 meters across in an open space with help or assistance and after the treatment session which patients were able to walk 10 meters or more without assistance in less period of time. Myalgia was also considerably reduced and General Health of individuals was better than pre-intervention. Patients were able to do activities of daily living well due to the therapies employed.

Conclusion

This study found out that there is a significant effect of Sensory Motor Integration Technique On Motor Dysfunction In Guillain-Barre Syndrome. There was significant decrease in disability in GBS patients after the intervention.

Conflict of Interest: There is no conflict of interest concerning the content of the study.

Source of Funding: This study was funded by Krishna institute of medical sciences deemed to be university karad.

Risk Factors for Ectopic Pregnancy: A Case Control Study in Tertiary Care Hospitals in Mangaluru

Sarah Abdul Azeez[1], Ayushi Prasad[1], Isha Kantor[1], Muskaan Arora[1], Sukriti Kaushik[1]

[1] 7th Semester MBBS Students, Kasturba Medical College, Mangalore

Abstract

Background: Implantation of the fertilised egg in a non-uterine environment is known as ectopic pregnancy. The extra uterine implantation does not support life and if left to grow can lead to the damage of nearby organs with life threatening loss of blood and several other morbidities.

Objective: The study was undertaken to determine the potential modifiable and non-modifiable risk factors for ectopic pregnancy, treatment and management.

Method: A case control study was conducted in Mangalore in May 2018 based on the medical records accessed from the Obstetrics and Gynaecology Department of Government Lady Goschen Hospital and Kasturba Medical College Hospital. Records of patients diagnosed with ectopic pregnancy and normal pregnancy were defined as cases and controls respectively and were assessed. A semi-structured pro forma was prepared. The information obtained was analysed using SPSS 17.0.

Results: The study included a study population of 142 (cases-68 and controls-74) Analysis of the obtained data led to the identification of several risk factors. Among them spontaneous abortion had the highest association with ectopic pregnancy accounting up to 50% followed by induced abortion accounting up to 45.6% of the case population. Multiple caesarean section account up to 17.6% of the case population.

Conclusion: It was concluded that the most potential risk factors for ectopic pregnancy include spontaneous and induced abortions, with multiple C sections being an antecedent cause none of which are modifiable.

Keywords: *Ectopic pregnancy, Risk factors, Abortion, Diagnosis, Management, Treatment.*

Introduction

Ectopic pregnancy is defined as the implantation of the embryo within the abdominal structures other than the uterus. Women belonging to the age group of 19-40 are at a higher risk for ectopic pregnancy. The major site of ectopic pregnancy (90 per cent) are the fallopian tubes which is clinically classified as tubal pregnancy, while other sites of attachment include the cervix, ovaries, abdomen etc.

Conditions that can lead to ectopic pregnancy include pelvic infection, infertility and priorectopic pregnancy, usage of contraception and prior LSCS and tubal surgeries. The warning signs of ectopic pregnancy include pain in the abdomen or pelvis, often expressed as a stabbing or sharp pain of varying intensity and duration and vaginal bleeding.

Organs other than the uterus are hostile to the embryo thus restricting its growth. As the embryo grows in size it leads to the breach of the neighbouring

e-mail: nithin.gatty@manipal.edu

structures and the ectopic site ultimately leading to massive haemorrhage. The aftermath of heavy bleeding is mostly hypovolemic shock.

The purpose of our research is to study the risk factors for ectopic pregnancy as well as to throw light upon its early diagnosis and management.

Materials and Method

In this case control study, obstetric records of 142 patients were analysed. The study was conducted in the month of May 2018 in the medical records department of Government Lady Goschen Hospital and Kasturba Medical College in Mangalore. It was a case-control study which included the medical records of those patients diagnosed with ectopic pregnancy in the last 10 years.

The total number of medical case records for consideration were 148.This sample size was calculated based on the findings of previous case control studies wherein 17.4% of controls had history of abortion with OR(Odds Ratio) of 1.93. By considering an alpha error of 5% and a power of 80% with equal ratios between cases and controls, the sample size was calculated to be 134. Further adding a non-response error of 10% increased the sample size to 148.

Data was captured using a semi-structured pro forma which was prepared after extensive review of literature. It consisted of 6 sections; Section A – General participant information; Section B- Current Obstetric History; Section C- Past Obstetric History; Section D- Gynaecology History; Section E- Contraceptive History; Section F- Lab and any other Investigations. The study protocol was approved by the Institutional Ethics Committee (IEC) of Kasturba Medical College, Mangalore. Permission was taken from the Dean of the institution as well as the Medical Superintendent of Katurba Medical College Hospital, Attavar and Government Lady Goschen Hospital to access the records from the Medical Records Department. The records were selected based on our definition of cases and controls and relevant study variables were entered into the pro forma.

Data was entered and analysed by using statistical software- Statistical Package for Social Sciences (SPSS) Version 17.0. Descriptive statistics like proportions, mean (Standard Deviation), median (IQR), was used for expressing the results. A chi square test was done for comparing the qualitative data between cases and controls. Both univariate and multivariate analysis (binary logistic regression) was done for determining the factors responsible for Ectopic Pregnancy. Odds Ratio and corresponding 95% confidence interval was reported and P value <0.05 was considered as statistically significant.

Results

Table 1: Demographic Comparison Between Cases and Controls (N= 142)

Characteristics	Cases n= 68	Controls n= 74	P Value *
	Mean (SD)	Mean (SD)	
Age (Yrs.)	30.7 (61)	26.5 (4.1)	< 0.0001
Age at marriage (Yrs.)	22.4 (5.5)	22.4 (3.9)	0.998

Significance: P Value < 0.0005 shows that females over the age of 30 years are at a greater risk for ectopic pregnancy.

Table 2: Comparison Of Current Obstetric History Between Cases and Controls (N= 142)

Risk Factors	Cases n= 68 n- (%)	Control n= 74 n- (%)	ODDS Ratio (Confidence interval)	P Value
History of vaginal discharge				
Yes	33 (48.5)	1 (1.4)	68.83 (9.0 -523)	< 0.0001
No	35 (51.5)	73(98.6)	-	-

Risk Factors	Cases n= 68 n- (%)	Control n= 74 n- (%)	ODDS Ratio (Confidence interval)	P Value
History of bleeding PV				
Yes	45 (66.2)	1 (1.4)	142.8 (18.64 – 1094)	< 0.0001
No	23 (33.8)	73 (98.6)	-	-

Significance: Given OR (68.83) and OR (142.8) signifies that the history of vaginal discharge is 68 times and history of bleeding PV is 142 times more amongst the women diagnosed with ectopic pregnancy as compared to women with normal intra uterine pregnancy.

Table 3: Comparison Of Past Obstetric History Between Cases and Controls (N=142)

Risk Factors	Cases n= 68 n- (%)	Controls n= 74 n- (%)	ODDS Ratio (Confidence Interval)	P Value
History of prior tubal surgery				
Yes	3 (4.4)	0 (0)	-	-
No	65 (95.6)	74 (100)	-	-
History of C section				
Yes	12 (17.6)	9 (12.2)	1.548 (0.60 -3.9)	O.371
No	56 (82.4)	65 (87.8)	-	-
History of spontaneous abortion				
Yes	34 (50)	9 (12.2)	7.222 (3.1-16.7)	0.0001
No	34 (50)	65 (87.8)	-	-
History of induced abortion				
Yes	31 (45.6)	2 (2.7)	30.16 (6.8 – 133)	< O.OO1
No	37 (54.4)	72 (97.3)	-	-
History of prior ectopic pregnancy				
Yes	4 (5.9)	0 (0)	-	-
No	64 (94.1)	74 (100)	-	-

Significance: Given OR (1.548), OR (7.222) and OR (30.16) signify that history of prior C Section, history of spontaneous abortion and history of induced abortion are seen 1.5, 7 and 30 times more amongst women who were diagnosed with ectopic pregnancy as compared to the women having normal intra uterine pregnancy respectively.

Table 4: Comparison Of Gynecology History Between Cases and Control (N=142)

Risk Factors	Cases n= 68 n- (%)	Controls n= 74 n- (%)	ODDS Ratio (Confidence Interval)	P Value
History of prior PID				
Yes	2 (2.9)	0 (0)	-	-
No	66 (97.1)	74 (100)	-	-
History of infertility				
Yes	5 (7.4)	1 (1.4)	5.794 (0.65 – 15.9)	0.096
No	63 (92.6)	73 (98.6)	-	-
Irregularity of menstrual cycle				
Yes	10 (14.7)	3 (4.1)	4.08 (1.07-15.5)	0.032
No	58 (85.3)	71 (95.9)	-	-
History of spotting or leaking PV				
Yes	30 (44.1)	1 (1.4)	57.63 (7.5 – 39)	< 0.0001
No	38 (55.9)	73 (98.6)	-	-

Significance: Given OR (5.794), OR (4.08) and OR (57.63) signifies that history of infertility, irregular menstrual cycle and history of spotting or leaking PV is seen 5,4 and 57 times more amongst the women who were diagnosed with ectopic pregnancy as compared to those with normal intra uterine pregnancy respectively.

Table 5: Comparison of Contraceptive History Between Cases and Controls (N=142)

Risk Factors	Cases n= 68 n- (%)	Controls n= 74 n- (%)	ODDS Ratio (Confidence Interval)	P Value
History of tubal ligation				
Yes	10 (14.7)	1 (1.4)	12.59 (1.5-101.2)	0.003
No	58 (85.3)	73 (98.6)	-	-

Significance: Given OR (12.59) signifies that history of tubal ligation is seen 12.59 times more amongst women who were diagnosed with ectopic pregnancy as compared to those with normal pregnancy.

Discussion

A successful spontaneous pregnancy is the outcome of a synchronized movement of the ovum and sperm to form a zygote at the ampullary isthmus junction, followed by implantation.[1]

The synchronized movement is the result of complex co-ordination between ciliary activity, muscular contraction and the flow of tubal secretions. [1] It has been found that cigarette smoking, endometriosis and various microbial infections have a profound impact on ciliary activity and tubal contractility leading to ectopic pregnancy and infertility. [1]

Despite continual improvements in medical facilities, ectopic pregnancy is the leading cause of mortality among women in their early trimester, accounting for up to 10 per cent of the total. [2] Global incidence of ectopic pregnancy accounts for up to 1-2 per cent, with the highest number of cases among those who adopted ART. [2] As reported by Centres for Disease Control and Prevention, 2.7 per cent of all pregnancy related deaths was due to ruptured ectopic pregnancy making it the foremost causes of haemorrhage related mortality. [2]

Our study revealed that 50 per cent of cases had histories of spontaneous abortion and 45.6 per cent had histories of induced abortion, therefore making the two the potential risk factors for ectopic pregnancy.

A similar study was conducted among Cameroonian women to identify the risk factors for ectopic pregnancy and the outcome of their study was strikingly different from ours as none of the four risk factors identified in their population were present in our study. [3]This included pelvic inflammatory disease, the use of emergency contraceptive pills like levonorgestrel (LNG-EC), previous use of depot medroxyprogesterone acetate (DMPA) and smoking during pregnancy. [3]

Another retrospective case control study conducted in 2017 and a case control study done in 2014 too concluded smoking at the time of conception and spouse's cigarette smoking as the leading cause of ectopic pregnancy. [4]

A prospective and descriptive study was carried out in Chennai to determine the risk factors for ectopic pregnancy. [5] The study bears considerable resemblance with our study by various factors, one being the incidence of ectopic pregnancy within the age range 18-45 years and one of the common risk factors being previous caesarean section. The study also revealed a success rate of 83.33% among patients who underwent methotrexate medical treatment. [5]

A study was conducted in 2019 to determine the pearl index of levonorgestrel intrauterine system (LNG-IUS) and its adverse effects. [6] The chances of ectopic pregnancy increases if the woman has taken LNG-IUS after the day of ovulation or has pre-existing pelvic inflammatory disease or endometriosis. [7]

A prospective cohort study conducted in America led to the conclusion that women who smoked or were heavy smokers, with significant exposure to diethyl-stilbestrol in utero, alcohol consumption of more than or equal to 10g/day, intake of oral contraceptive pills since adolescence or with a history of infertility, tubal ligation and usage of intrauterine devices are prone to ectopic pregnancy. [8]Two of the risk factors that reflected in our study too are infertility and tubal ligation accounting up to 7.4 % and 14.7 % of the cases.

A systematic review of a case report on abdominal ectopic pregnancy after IVF-ET was done in 2016. [9] IVF-ET was carried out in these patients which resulted in 46% of heterotopic abdominal pregnancy and abdominal ectopic pregnancy accounting up to 54%. [9]

The regulation of smooth muscle contraction and signalling during initiation of primordial follicle formation in human foetal ovary is due to the expression of protein prokineticin receptor 1, encoded by PROKR1 gene. [10]

The chief component of tobacco or cigarette smoke nicotine increases the expression of PROKR1. Nicotine not only increases but also alters the expression of PROKR1 which results in altered tubal motility. [10] This results in delayed transport of ovum to during the time conception, resulting in infertility.

A cohort study conducted in the Middle- East throws light upon the various factors that could lead to the recurrence of ectopic pregnancy in women. [11] This included previous miscarriages, extraction of retained products of conception, poor surgical treatment approach and inadequate haemoglobin level at the time of first ectopic pregnancy. [11]

Chlamydia trachomatis infection and gonorrhoea leading to tubal infection can be a potential platform for the occurrence of ectopic pregnancy by forming abscesses in the fallopian tubes leading to fluid accumulation. Even after an effective treatment a scar can be formed in the fallopian tube which can obstruct the passage of the ovum. [12]

In 2015, a descriptive hospital based study was conducted in Assuit University Egypt and remarkably, the potential risk factor recognized among the patients was internal venereal disease accounting for up to 72.5 per cent. [13] The following year, a retrospective study regulated by the Department of Obstetrics and Gynaecology, Thanjavur Medical College, Tamil Nadu identified pelvic infection (15.7 %), previous ectopic pregnancy (8.33%) and infertility (7.01%) as the most common risk factors. [12]

In TVS the presence of 'blob' sign is indicative of tubal pregnancy whereas interstitial line sign is indicative of interstitial ectopic pregnancy. [14] TVS coupled with beta HCG test makes the ultimate diagnostic modality for ectopic pregnancy. [14]

The success of ectopic pregnancy treatment and management depends upon the feasibility, patient's compliance, cost, equipment and trained health care personnel. [15] Though ectopic pregnancy is identified promptly on TVS the treatment technique to be undertaken depends upon the haemodynamic stability of the patient. [15]A haemodynamically stable patient with low initial serum beta-HCG concentration and no signs of active bleeding or rupture of tubes can undergo a non-invasive outpatient medical treatment like systemic methotrexate with regular follow up. [15][16]

From all the studies conducted across the world it is possible to conclude that smoking, pelvic infection and usage of emergency contraception are the major risk factors in the Western and developed countries. Whereas in developing countries like India, previous abortions and ectopic pregnancy, multiple caesarean section and tubal surgeries are the widely identified risk factors.

Therefore, to prevent recurrence of ectopic pregnancy early diagnosis and management of primary ectopic pregnancy with transvaginal sonography, human chorionic gonadotropin assay, systemic methotrexate or laparoscopy must be revolutionized.

Conclusion

On evaluating the data collected in our research "Risk Factors For Ectopic Pregnancy – a case control study in tertiary care hospitals in Mangaluru "we can conclude that the factors that account as the most potential risk for ectopic pregnancy include spontaneous and induced abortions, with multiple C sections being an antecedent cause .

Comparison of Color, Coverage and Caries (CCC) Evaluation System and Simonsen's Criteria in Assessing the Retention of Pit and Fissure Sealants

Seema Abdul Gani[1], Ramesh Nagarajappa[2], Mohammed Abid[3], Soumya Shetty[4]

[1]Post-doctoral Research scholar, Pacific Academy of Higher Education and Research University, Udaipur, Rajasthan, [2]Professor and Head, Department of Public Health Dentistry, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, [3]Private Consultant, Gulbarga, Karnataka, [4]Professor, Department of Conservative Dentistry and Endodontics, Padmashree Dr. DY Patil Dental College and Hospital, Pimpri, Pune, India

Abstract

Objectives: The purpose of this study was to compare the efficacy of Color, Coverage and Caries (CCC) evaluation system and Simonsen's criteria in assessing the retention of pit and fissure sealants.

Materials and Method: Sixty children with the age group of 6-8 years were chosen for a split mouth randomized clinical trial. Permanent mandibular first molars on either side were treated with 37% phosphoric acid [Vococid (VoCo)] followed by the application of a resin-based sealant [Clinpro TM 3M ESPE, USA]. The teeth were then evaluated on one side with CCC evaluation system and the other side with Simonsen's criteria at a period of six, twelve and eighteen months respectively. The results were calculated, tabulated and statistically analyzed using SPSS version 21 software (IBM SPSS Statistics, IBM Japan, Tokyo, Japan). On the basis of categorical scores given to retention of sealants, Pearsons Chi-square test was used for analysis. The level of significance was set at $p<0.05$.

Results: Complete retention was found in 86.7%, 80% and 71.7% of the subjects at the end of six, twelve and eighteen months respectively using CCC evaluation system. Sealant covering more than 50% was found in 10%, 11.7% and 13.3% at the similar recall intervals respectively whereas sealant was missing in only 1.7% and 6.7% at the end of 12 and eighteen months respectively. This difference was not statistically significant ($p>0.05$). When the sealants were evaluated using the Simonsen's criteria, it was observed that complete retention were seen in 85%, 76.7% and 70% of the children at the end of six, twelve and eighteen months respectively. Partial retention of sealants was observed in 15%, 21.7% and 23.3% of subjects at the end of six, twelve and eighteen months respectively. This difference was not significant ($p>0.05$). Almost similar results were obtained when both CCC evaluation system and Simonsen's criteria were compared.

Conclusion: This study concluded that CCC evaluation system appears to be a convenient method for use to evaluate sealed surfaces and provides a flexible tool for the clinician, researcher and academics. However, Simonsen's criteria is also a simple method to assess retention of sealants as it records the presence or absence of sealants in the occlusal surfaces.

Introduction

Dental caries has been the point of concern globally for its progressive and inescapable nature of decaying teeth. This is particularly because of the anatomy of the tooth which favors the stagnation of bacteria and their products which ultimately leads to destruction of the

dental tissues.[1] In spite of various preventive procedures such as fluoride treatment, oral hygiene measures, dietary modifications; caries continues to play in the progression of decay in the tooth.

Sealants have been introduced in the market to seal the pit and fissures that could prevent further stagnation of microorganisms. But for an effective bonding, the enamel surface has to be completely free of any debris and the pellicle for deeper penetration of the sealants into fissures.[2] This can be achieved by the use of various pretreatment techniques such as acid etching, air abrasion, air polishing, laser etching and ozone applications. The sealant retention can, therefore, be expected to increase after these procedures. However, sealant integrity requires periodic follow-ups for the effective prevention of dental caries.

Sealants need to be assessed for a clinician planning patient health care, to reapply sealant if the sealants are lost and to monitor the caries. The prime factors required to assess sealant retention is sealant identification, coverage, color, caries status and the differentiation between the preventive and restorative sealants.[3-6] The Color, Coverage and Caries (CCC) Evaluation system described by Deery et al. is a simple, legitimate and reproducible method to detect sealant integrity since it helps to determine all the three factors (Color, Coverage and Caries) responsible for sealant retention.[3]

Simonsen's criteria are based on the amount of sealant retained on the tooth surface. Accordingly, they are classified as: 1) Completely retained; 2) Partially retained and 3) Missing. Because of its simplicity, convenience, high reliability and validity, it has been used commonly to evaluate sealant retention in several studies.[4-11] An unreliability still exists in the system of sealant evaluation even after years of research studies. Unfortunately, we could not find literature related to comparison between the CCC evaluation system and Simonsen's criteria. Therefore, this study was conducted with the research hypothesis of comparing the efficacy of two sealant evaluation systems - CCC Evaluation System and Simonsen's criteria.

Materials and Method

The present study was a split mouth randomized clinical trial conducted on 6-8 years old children after obtaining ethical approval from the institution. Informed consent was obtained from parents who were informed that strict confidentiality would be maintained throughout the course and they were free to withdraw their child. Also, the children were benefitted with any other oral treatment if they needed for free.

A co-operative child having permanent erupted mandibular molars with no history of cavitation, previous restoration or sealants were included in the study. Children with medically compromised conditions contra indicating the treatment of teeth were excluded. Before starting the procedure, intra-examiner reliability was calculated by examining a group of 5 children and the re-examination was carried out at least 30 minutes after the initial examination. The kappa value was 0.88, which denoted substantial level of agreement between the examinations.

The sample consisted of 60 children with 60 teeth per group. Group 1 was evaluated using CCC evaluation system and Group 2 by Simonsen's criteria. Each child selected for the study received sealants in the form of split mouth design. The right permanent mandibular first molars were first etched followed by sealant application and were then evaluated using CCC evaluation system during recall visits. The left mandibular first molars were treated in the same way but were evaluated at the recall visits using Simonsen's criteria.

The protocol for the procedure was as follows:

- The children were asked to dry brush their teeth while waiting for their turn of treatment.
- The surfaces were then cleaned with prophylaxis paste utilising pumice and water for 15 seconds and dried lightly with packed oil-free air.
- The permanent mandibular first molar was etched using 37% phosphoric acid gel [Vococid (VoCo)] for fifteen seconds followed by flushing with water for 15 seconds and air dried. Strict isolation was maintained throughout the procedure using cotton rolls and suction.
- The teeth were then sealed with a pit and fissure sealant [Clinpro TM 3M ESPE, USA] utilising a syringe provided by the producer.
- Any excess sealant was removed with an explorer and light cured for twenty seconds. The color of the sealant changed from pink to opaque white on curing.
- Occlusal adjustment was done using composite finishing strips after checking for any high points.

- Patients were released and planned for review visits at an interval of six, twelve and eighteen months interim.

The method of examination was visual using blunt probe and mirror.

Group 1: Patients scheduled for recall visits were evaluated for sealant retention using CCC evaluation system and the codes used for evaluation were as follows:

Sealant covering all of the fissure system

Sealant covering more than 50% of the fissure system but some sealant missing

Sealant covering less than 50% of the fissure system

Group 2: Sealants were evaluated at recall visits using Simonsen's criteria. The categories of evaluation were as follows:

Completely Retained: Presence of sealant with some amount of wear such that ledges are not seen which indicate bulk amount of sealant loss. Also, there should be no exposure of pits and fissures due to loss of sealant.

Partially Retained: Part of sealant present due to some wear, pits or fissures or both are exposed due to loss of sealant.

Missing: Complete loss of sealant.

Statistical Analysis: The results were calculated, tabulated and statistically analyzed using SPSS version 21 software (IBM SPSS Statistics, IBM Japan, Tokyo, Japan). On the basis of categorical scores given to retention of sealants, Pearsons Chi-square test was used for analysis. The level of significance was set at $p<0.05$.

Results

Table 1. Sealant coverage at different intervals evaluated with CCC evaluation system.

CCC criteria of sealant retention	Six Months N (%)	Twelve Months N (%)	Eighteen Months N (%)
Complete sealant coverage	52 (86.7)	48 (80)	43 (71.7)
Sealant covering more than 50%	6 (10)	7 (11.7)	8 (13.3)
Sealant covering less than 50%	2 (3.3)	4 (6.7)	5 (8.3)
No sealant present	0 (0)	1 (1.7)	4 (6.7)
Total	60 (100)	60 (100)	60 (100)
Chi Square test	7.35		
P value	0.296		

Sixty children were recruited in this split mouth clinical trial and all of them participated till the end of the study. Complete retention was found in 86.7%, 80% and 71.7% of the subjects at the end of six, twelve and eighteen months respectively. Sealant covering more than 50% was found in 10%, 11.7% and 13.3% at the similar recall intervals respectively whereas sealant was missing in only 1.7% and 6.7% at the end of 12 and eighteen months respectively. This difference was not statistically significant ($p>0.05$).

Table 2. Sealant coverage at different intervals evaluated with Simonsen's criteria

Simonsen's criteria of sealant retention	Six Months N (%)	Twelve Months N (%)	Eighteen Months N (%)
Completely retained	51 (85)	46 (76.7)	42 (70)
Partially retained	9 (15)	13 (21.7)	14 (23.3)
Missing	0 (0)	1 (1.7)	4 (6.7)
Total	60 (100)	60 (100)	60 (100)
Chi Square test	12.28		
P value	0.212		

When the sealants were evaluated using the Simonsen's criteria, it was observed that complete retention were seen in 85%, 76.7% and 70% of the children at the end of six, twelve and eighteen months respectively. Partial retention of sealants was observed in 15%, 21.7% and 23.3% of subjects at the end of six, twelve and eighteen months respectively. This difference was not significant (p>0.05).Almost similar results were obtained when both CCC evaluation system and Simonsen's criteria were compared.

Discussion

The vulnerability of the pits and fissures to retain the micro-organisms and their byproducts because of their morphology has been an extreme concern with regard to the progression of dental caries.[5] However, application of sealants to these pits and fissures can overcome the development of caries as the sealants prevent the access to bacteria and their by products deep into the fissures. For an effective prevention method to sustain, it is imperative that the sealants be monitored for their retention periodically. There has not been a standardized method of assessing and evaluating the retention of sealants for a clinician planning recall visit. Many previous studies have used different criteria or have used their own to assess the retention of sealants.[6-9] We could not find any study that compared the evaluation systems to assess the retention of sealants such as CCC evaluation system and Simonsen's criteria. The present study necessitates the importance of the same and was therefore performed to compare the evaluation of sealant integrity using CCC evaluation system and Simonsen's criteria.

When the sealants were evaluated using CCC sealant evaluation system, complete retention was seen in 86.7% and sealant covering more than 50% was found in 10% at the end of six months. Similar findings were observed in the study of Khatri et al.[10] where at 6 months, complete sealant retention was observed in 78% teeth and at the end of 12 months, 71.9% sealants were completely retained. Mohammed et al.[11] found 66.7% complete sealant retention and 23.3% for sealants covering more than 50% of the occlusal surfaces at the end of six months. However, Fray et al.[12] found 90.47% complete loss of sealants and 9.53% of sealant in less than 50% of the fissures system at the end of six months.

Retention of sealant can be described in several ways. For example, some studies have reported sealant coverage according to 'sites' rather than the whole surface. In these cases, sealant covering half of the occlusal surface can be reported as complete coverage according to 'sites' criteria whereas the same would be regarded as 50% when it is categorized according to whole surface. Such results when directly compared could be misleading. CCC evaluation system has been considered by many researchers to be simple, effective, flexible and constructive as it determines all the three important criteria required to assess the retention of sealant that is discoloration, sealant coverage and development of dental caries.[3,12,13] When the sealants were evaluated using Simonsen's criteria, 85% of sealants were completely retained as compared to 15% of sealants that were retained partially at the end of six months. Similarly, 12 months results showed 76.7% complete retention as opposed to 21.7% partial retention. These findings were similar to the results of Ratnaditya et al.[14] where complete retention was observed in 82% of sealants at the end of six months and partial retention was observed in 9% of sealants. However, Simonsen[15] in his clinical evaluation of sealants for 24 months found complete retention in 96.7% which was quite high. Simonsen's criteria has been preferred by many authors due to its clarity, ease of use, reliability, high validity and reproducibility.[4,16,17] When both CCC evaluation system and Simonsen's criteria were compared, the CCC evaluation system was found to be more reliable and consistent in the form of assessment as it was efficient in recording all the prime factors responsible for the efficacy of sealant that is discoloration, sealant coverage and development of dental caries. Simonsen's criteria on the other hand are simple to follow but do not cover all the aspects required for sealant retention.

Conclusion

This study concluded that CCC evaluation system appears to be a convenient method for use to evaluate sealed surfaces and provides a flexible tool for the clinician, researcher and academics. However, Simonsen's criteria is also a simple method to assess retention of sealants as it records the presence or absence of sealants in the occlusal surfaces. This can be a beneficial tool for researchers assessing only retention of particular surface rather than the other prime factors such as discoloration and presence or absence of dental caries responsible for the assessment of the efficacy of sealants.

Assessment of Knowledge, Attitude and Practice of Parents on Childhood Immunisation Programme in a Tertiary Care Hospital in Calicut

Shaimol T.[1], Sruthy Maria Johns[2], Sharafudheen T.P.[2], Lufna Rai[2], Sanjay Sreekumar[3], Parvathy S.[4]

[1]Assistant Professor, [2]Pharm D. Intern, [3]Assistant Professor, Department of Pharmacy Practice, Devaki Amma Memorial College of Pharmacy, Malappuram, Kerala, India, [4]Paediatric Consultant, PVS Hospital (P) Ltd, Calicut, Kerala, India

Abstract

Background: Immunization is an important factor for preventing the severe infections disease in humans. This study is to assess the Knowledge, Attitude and Practice to the immunization schedule of paediatrics by their parents using a questionnaire in a tertiary hospital at Calicut.

Methodology: A prospective observational study that was carried among the parents of kids in the Paediatric O.P department of PVS hospital, Calicut. A questionnaire was prepared and administered to the parents to assess their KAP, on immunization.

Result: A total of 200 participants were included in the study. Around 40% parents had good knowledge, 80% had positive attitude 89% had revealed positive practice towards immunization. Maternal education (χ^2=35.64; p<0.01) and area of living (χ^2=22.99; p<0.01) were significantly associated with knowledge of mothers .Maternal education level (χ^2=20.76; p<0.01) were significantly associated with favourable attitudes. Good infants immunization practice was significantly associated with number of children in a family (χ^2=12.15 p<0.002). About 50 (42.3%) cases of child being ill were identified as a reason for vaccine hesitancy from 118 cases (59%).

Conclusion: The majority of the respondents have positive opinion about the importance of childhood immunization in study areas. However, some respondents had insufficient knowledge on this issue. Educational intervention should be recommended to improve this scenario and recommended special emphasis on the rural area.

Keywords: *Childhood immunization, Knowledge, Attitude, Practice.*

Introduction

The World Health Organization (WHO) has defined immunization as the process whereby a person is made immune or resistant to an infectious disease, typically by the administration of a vaccine. These vaccines help to stimulate the body's own immune system to protect the person against subsequent infection or disease. Immunization is one of the most successful and cost effective public health interventions in the constant effort of human beings against diseases that affect our well-being.[4] Vaccination has made an enormous contribution to global health. Global vaccination coverage against many important infectious diseases of childhood has been enhanced dramatically since the creation of WHO"s Expanded Programme of Immunization. Parental decisions regarding immunization are very important

for increasing the immunization rate, compliance and for decreasing any possible immunization errors. Parent's knowledge, attitude and practices regarding immunization are the major factors that contribute to their vaccination decisions. There are many barriers against immunization, including misinformation about vaccines, lack of proper knowledge regarding minor adverse effects of vaccines and very few contra indications of vaccines.[10]

In recent years, vaccine hesitancy has been the subject of growing attention as an emerging term in the literature.[11] A critical factor shaping parental attitudes to vaccination is parent's interaction with the healthcare professionals. An effective interaction can address the concerns of the vaccine supportive parents and motivate a hesitant parent towards vaccine acceptance. Conversely, poor communication can contribute to rejection of vaccination or dissatisfaction with care. To improve parent's awareness, good knowledge regarding vaccination is required. Therefore, physicians, pharmacists, nurses and others health care providers should provide parents with correct information about the advantages ofvaccines.[14]

Material and Method

A prospective observational study design was done in the Paediatric outpatient department of PVS Hospital (P) Ltd, Calicut for 6 months (October 2017 – April 2018). The study was conducted after attaining approval from the institutional ethics committee of the hospital and informed consent form was obtained from the parents. The parental Knowledge, Attitude and Practice were assessed using pre- designed questionnaire via interview. The pre-designed questionnaire contains 3 domains in it. The first domain was included with the socio-demographic data of the parents.The second domain had 45 multiple choice questions related to Knowledge, Attitude and Practice. There were 15 questions each for Knowledge, Attitude and Practice. The response that were given choice were 'Yes', 'No' and 'Occasionally' for Knowledge, 'Agree', 'Disagree' and 'Uncertain' for Attitude and 'Yes', 'No' and 'Don't Know' for Practice. The third domain had questions related to the Vaccine hesitancy. Scores of the questions were determined in such a way that the correct answers were given a score of two, wrong answer with score zero and indefinite, unclear were given a score of one. The respondents to knowledge based questions were divided as 'Good', 'Fair' and 'Poor'. The 'Good' included score more than 65%, 'Fair' 51%-65% and 'Poor' was less than or equal to 50%.The respondents of Attitude and Practice based questions were divided using Median Split Method as 'Positive' and 'Negative'. The 'Positive' had included greater than and equal to 60% and 'Negative' included with less than 60%.These scoring techniques was first checked and validated by performing a Pilot study with a sample size of 20 parents. After the interview if the parents showed a 'Fair' or 'Poor' Knowledge, Attitude and Practice then the parents were given with a short session of verbal counselling and provided with Patient Information Leaflet on Immunisation. The Patient Information Leaflet had basic information on vaccination, the need, the controversies faced and their scientific reasoning along with the Immunisation Schedule followed in the hospital. The collected data was correlated with the Socio-demographic data of the parents by using Statistical analysis. The impact of counselling were determined, whether the short session of counselling had made a change in the attitude of the parents. Statistical analysis was performed using chi-square test and SPSS software 4 windows version 20.

Findings:

Socio-demographic characteristics: Among 200 parents interviewed 176 were females of which 142 were housewives. Maximum numbers of parents (136) were in the age group of 26 to 35years, 106 parents had 2-3 children. 142 parents came from a rural area. There were 104 parents with UG or PG level of education.

Parents Knowledge: The overall knowledge of the 200 parents on immunization was found to be Fair [108(54%)].

Influence of socio-demographic characteristics on knowledge:

The level of education was significantly associated (X^2 value = 35.65, p value = <0.01) with how knowledgeable parents were on immunization. Most of the parents with a UG/PG level of education (Good: 60; Fair: 38; Poor: 6) were found to respond correctly to the questionnaire. The location or geographical area had also shown significant association (X^2 value = 22.99, p value = <0.01) with parent's knowledge on immunization.

Parents Attitude: The overall attitude of the parents on immunisation was found to be positive as about 80% of parents were found to have a positive attitude.

Influence of socio-demographic characteristics on Attitude: The level of education was significantly associated ((Chi^2 value = 20.769, p value = <0.01) with positive attitude of parents on immunisation, the higher the education, the more positive their attitude towards immunisation [UG/PG: 94(58.35%)].

Parent's Practice: The overall practice of the immunisation was found to be positive as almost 89% of parents were found to have a positive attitude.

Influence of socio-demographic characteristics on Practice: The number of children was significantly associated (Chi^2 value = 12.15, p value = 0.002) with practice of the parents. The association was found to be a negative association as increased number of children showed an increase in negative practice for immunisation.

Vaccine Hesitancy: Vaccine hesitancy here indicates the delay or refusal for vaccination by the parents. There were a total of 118 (59%) cases of vaccine hesitancy. The most common reason observed was, the child being ill"; that was about 50 (42.3%) cases

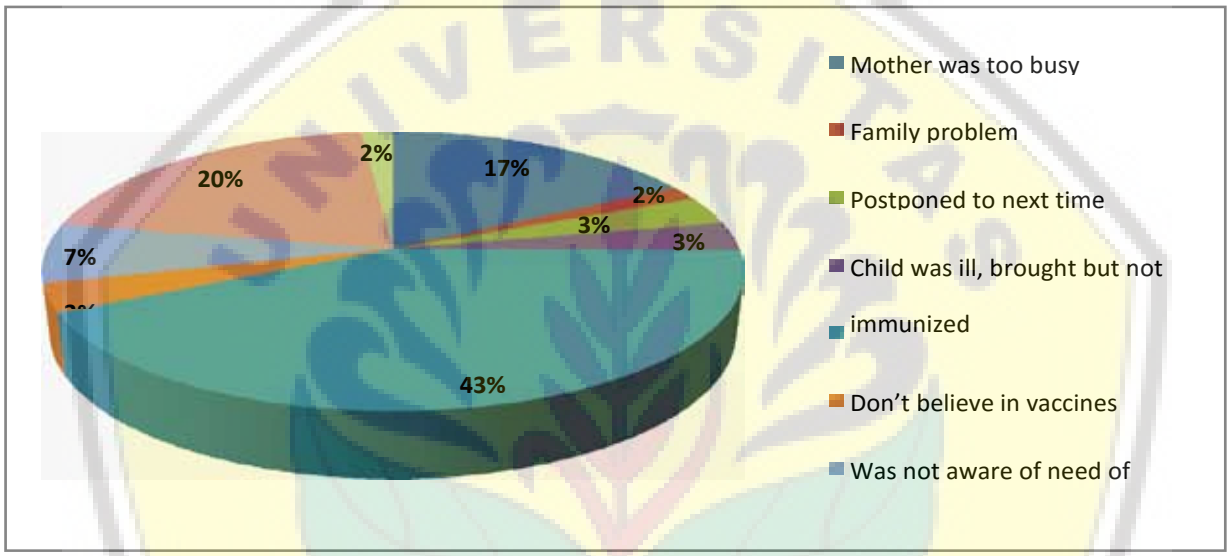

Figure 1: Distribution of reasons for Vaccine hesitancy

Impact of counselling on Vaccine hesitancy: Out of 200 parents included in the study 24 parents showed a negative attitude and hesitancy on vaccination due to the reason of hearing bad things about Immunisation. With the help of verbal counselling along with patient information leaflet and scientific literatures we were able to minimise their hesitancy towards vaccination to an extent.

Table 1: Reasons for parent's negative attitude towards vaccination

Sl.No.	Aspects on Vaccination	Parents Showed Hesitancy
1.	Infertility	14
2.	Pulse polio (extra dose)	3
3	Herd Immunity	5
4	Religion	2

Conclusion

Overall prescribing practices were in fair compliance with guidelines but still have a room for further improvement. Compliance to JNC 8 guideline resulted in better hypertension control in patients suffering from cardiovascular comorbidities. Poor adherence to guidelines in patients suffering from Diabetes mellitus and poor control among patients receiving mono therapy are the areas which need further probing and focus in the future. Different strategies like continuous medical education, seminars, reminder tools and the availability of clinical pharmacist to participate in collaborative practices and motivating patients to participate in BP goal achievement could increase guideline adherence and hypertension control.

Conflicts of Interest: The authors of this study

declare that there are no conflicts of interest regarding the publication of this article

Ethical Clearance: The study was conducted after attaining Approved by the Institutional Ethics Committee, P V S Hospital (P) LTD, Calicut and Kerala Ref. No. PVS/EC/02/17-18 (Dated on24/01/2017) and informed consent form was obtained from the parents.

Effect of Audio Assisted Relaxation Therapy on Level of Blood Pressure among Mothers with Pregnancy Induced Hypertension

Shasi Bala[1], Lekha Viswanath[2]

[1]Post Graduate Student, [2]Professor, Himalayan College of Nursing, Swami Rama Himalayan University, Dehradun cum Vice-Principal, Akal College of Nursing, Eternal University, Baru Sahib, Dist. Sirmour, Himachal Pradesh, India

Abstract

Introduction: The incidence of PIH is about 8-10% of pregnancies. Hypertensive disorder of pregnancy if unchecked will result in eclampsia with generalized convulsions, HELLP syndrome etc. It is usually managed with medicines. There are various non-pharmacological treatment like muscle relaxation, meditation, breathing etc. which are used to control of hypertension. Present study was aimed to assess the effectiveness of audio assisted relaxation therapy on level of blood pressure among mother with pregnancy induced hypertension.

Method: Experimental approach with one group pretest- posttest design was used for the study. Study was conducted among 30 antenatal mothers diagnosed with PIH admitted in Kamla Nehru Hospital, Shimla H.P, selected by using convenience sampling technique. Semi structured interview schedule is used to collect background information and sphygmomanometer was used to measure the level of blood pressure. The blood pressure (BP) was monitored three times a day for two days to obtain a baseline data and average of it was considered as pre-test. Audio assisted relaxation therapy was then administered for 20 minutes per sessions, two times a day for three days. The blood pressure (BP) was monitored before and after each session of relaxation therapy

Results: The mean posttest systolic is BP, 139.81 mm of Hg was significantly lower than the mean pretest systolic BP, 146.45 mm of Hg. The mean posttest diastolic BP, 87.63 mm of Hg was also ower than the mean pretest diastolic BP, 92.06 mm. Both differences were significant at the level of <0.001.

Discussion: The result of present study shows there is a significant difference in BP before and after intervention. So audio assisted relaxation therapy can be used as an effective add on intervention for the management of with women hypertension during pregnancy.

Keywords: *Pregnancy induced hypertension, Audio Assisted relaxation Therapy, Pregnant Mothers, blood pressure.*

Introduction

Pregnancy-induced hypertension (PIH) is a condition which present with high blood pressure with or without proteinuria and edema, with other clinical manifestation usually occurring late in pregnancy and regressing after delivery of the conceptus[1].

According to American College of Obstetricians and Gynecologists (ACOG) 2013 guidelines, the criteria for PIH is systolic blood pressure of 140 mm Hg or higher, or diastolic blood pressure of 90 mm Hg or higher occurring after 20 weeks of gestation in a pregnant mother whose blood pressure (BP) has previously been normal. Preeclampsia is diagnosed by persistent high BP that develops during pregnancy or during the postpartum period that is associated with a lot of protein in the urine or visual disturbances[2,3]. Indian scenario the incidence of PIH ranges from 5-15% in the

primi gravid mothers, whereas it is 16% in multigravida mothers[4]. Several epidemiological studies have been performed to determine the prevalence and risk factors of hypertensive disorder of pregnancy (HDP) as well as its subtypes. It was found in a study taht prevalence of HDP is 5.2–8.2%, gestational hypertension 1.8–4.4% and preeclampsia is 0.2–9.2%, respectively[5]. WHO estimates that out of 5,29,000 maternal death reported globally each year, 1,36,000 (25.7%) was contributed by India. Among these 16% are due to pregnancy related complications. According to WHO census 2010 the risk of a woman dying from a pregnancy-related cause is about 36 times higher during her lifetime in a developing country as compared to a woman living in a developed country.[6] According to WHO censes 2013 every year Nearly 76,000 women die globally due to preeclampsia[7]. Global scenario incidence of PIH is range from 1 to 35%. WHO estimates the incidence of preeclampsia to be seven times higher in developing countries[8]. Incidence rate of PIH is 8-10% in India[9].

According to WHO expert committee and Joint National Committee recommends non pharmacological treatment like muscle relaxation, meditation, breathing therapy as the first measure used to control of hypertension. Relaxation therapy is beneficial as it counteracts the physiological effects of stress and fight or flight response.[10,11,12] Present study was aimed to assess the effectiveness of audio assisted relaxation therapy on level of blood pressure among mother with pregnancy induced hypertension.

Materials and Method

The aim of the study was to find out the effectiveness of audio assisted relaxation therapy on level of blood pressure. So an experimental approach was appropriate for the study. One group pretest- posttest design with multiple observations is used for this study. As BP is a variable which is subject to variations due to the effect of many external and internal factors, average of three observations per day for two days was obtained to get the baseline blood pressure. The average of baseline measures is considered aspretest. Average of three observations on the last day was considered as the posttest. Intervention included the administration of audio assisted relaxation for 20 minutes two times a day for three days. In order to find the immediate effect of each session of audio assisted relaxation, the blood pressure level before and after intervention was measured.

The setting of the study was Kamala Nehru Hospital, Shimla Himachal Pradesh (KNH).A sample of 30 antenatal mothers diagnosed with PIH admitted in Kamala Nehru Hospital District Shimla, Himachal Pradesh was recruited for the study by using convenience sampling technique. The study included mothers who are willing to take part in the study, diagnosed with PIH and admitted in KNH and understand Hindi or English. The study excluded the mothers whose medication or dose changed in the past three days, variability in BP more than ten mmhg between mean of first and second day, having complications like eclampsia, HELLP syndrome and having mental illness.

A detailed explanation was given to participants about the purpose of the study and intervention and it was informed that intervention does not cause any harm to them. Participation was based on their willingness and written informed consent was obtained from each participant prior to data collection and they were allowed to withdraw from the study at any point. On recruitment Semi-structured interview schedule was used to collect Background information. Sphygmomanometer was used to measure the Level of blood pressure at the specified intervals and blood pressure was recorded in a flow sheet.

Audio assisted relaxation therapy (AART)was given to antenatal mothers along with routine medication and care. AART included sessions of guided relaxation of 20 minutes duration administered to mothers with PIH, with the help of prerecorded instructions by using headset for three continuous. It was developed and validated by experts in relaxation therapy. The intervention was administered in a separate quite room and was guided by prerecorded instructions. The mother was allowed to assume a sitting or side lying position as per her comfort and preference. The technique used for relaxation is focused attention. It is a prerequisite for meditation as a person is required to channelize all his attention to a specific sound and his breath. Focused attention helps in keeping the mind free from any distractions and channelizing thoughts in one direction towards slow breathing

The data was analyzed using frequency and percentage for distribution of background information. Mean and standard deviation and Paired t test to compare pretest and posttest level of blood pressure.

Results

Background information: Based on demographic variables majority 73.3% of mothers were in age between 19-30 years, 43.3% of them having diploma or degree and 76.6% of mothers were homemaker. Majority 53.3% of women's were belongs to joint family. Majority 30% of mothers were having monthly income of 10001-20000 monthly family income. About 66.6% of mothers were primigravidae and 46.6% of them were in gestational week between 36-40 weeks. None of them from any coexisting complications during pregnancy.

Based on PIH related data 40% of mothers were diagnosed with pregnancy induced hypertension at 31-35 weeks of pregnancy. Majority 60% of mothers were taking Labetalol for the treatment of PIH and also among them 51% of mothers used 50 mg dose for once a day. Majority, 87% of mothers were not received any teaching regarding relaxation therapy. About 20% of mothers reported to receive some informal teaching regarding management of PIH by restriction in diet like salt and oil free diet, avoid stress, positioning, fluid intake etc. None of them were not using any Non Pharmacological method.

Baseline Level of Blood Pressure:

Table 1. Frequency and Percentage Distributions based on baseline level of Blood Pressure: N=30

Variables	BP in mm of Hg	Frequency	Percentage
Level of systolic BP at the time of diagnosis	Less than 140	1	3%
	141-150	20	67%
	151-160	7	23%
	161-170	2	7%
Level of diastolic BP at the time of diagnosis	Less than 90	3	10%
	91-95	17	57%
	96-100	8	27%
	101-110	2	7%
Level of systolic BP on the day of recruitment.	130-140	5	17%
	141-150	14	46.6%
	151-160	11	36.4%
Level of Diastolic BP on the day of recruitment.	86-90	2	7%
	90-95	12	40%
	96-100	16	53%

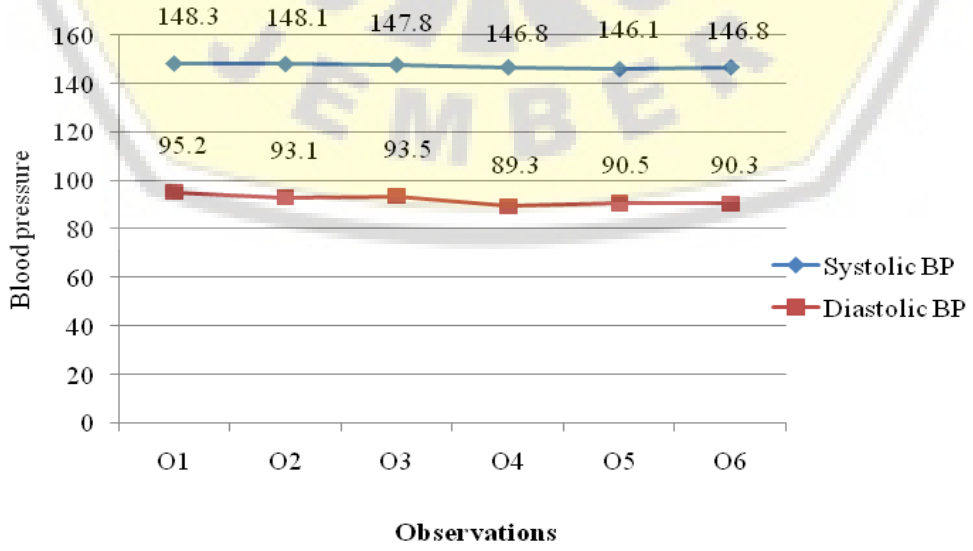

Fig 1: Line graph showing the mean blood pressure on first and second Day (N=30)

Figure no 1 shows that systolic and diastolic BP in first and second day was stable. Systolic BP of first and second day ranges from 148.3 mm of Hg to 146.8 mm of Hg and diastolic BP ranges from 95.2mm of Hg to 90.3mm of Hg.

Effect of Audio assisted relaxation therapy on level of blood Pressure:

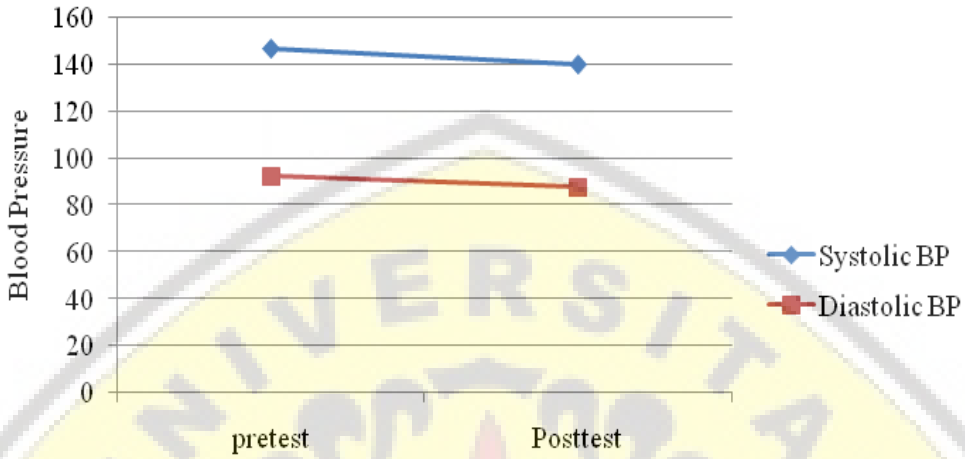

Fig. 2 Line graph showing the mean of pretest and posttest Systolic and Diastolic BP (N=30)

The fig. 2 shows that the mean systolic and diastolic BP is lower in posttest than the pretest. The pre-test systolic and diastolic BP is lower than the prestest with each session of the interventions (Fig. 3).

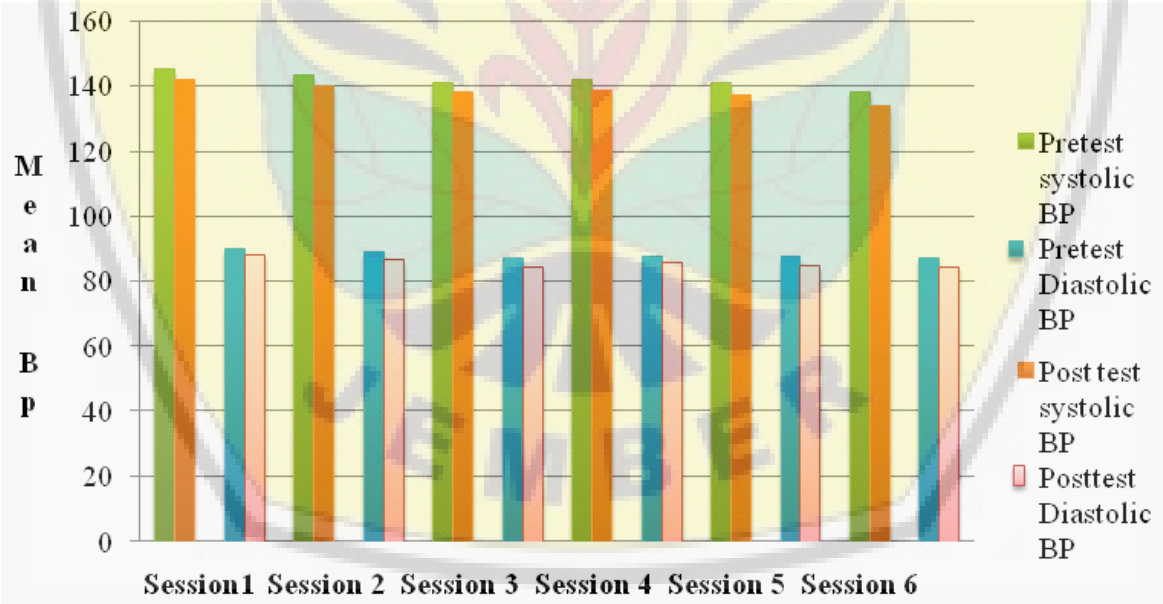

Fig. 3. Bar diagramme showing the immediate pretest and posttest systolic and diastolic blood pressure with each session of audio assisted relaxation (N=30)

Table: 2. Comparison of pretest and posttest Systolic and Diastolic blood pressure. N=30

	Pretest BP Mean± S.D.	Posttest BP Mean± S.D.	Mean Difference	t value	P value
Systolic BP	146.45±7.846	139.81±8.103	6.643	5.314	0.000**
Diastolic BP	92.06±3.820	87.63±5.581	4.427	5.101	0.000**

** Highly significant at P<0.001

Table 2 showed that there was significant (P<0.001) difference in the systolic blood pressure and diastolic blood pressure in pre-test and post- test. The mean pre-test scores of Systolic BP was 146.45 & diastolic BP was 92.06 significantly higher than the mean of post -test scores of Systolic BP was 139.81 & diastolic BP was 87.63. Hence, the null-hypothesis H_{01} was rejected and the research hypothesis was accepted.

Table: 3. Comparison of pre-test and post-test Systolic blood pressure for mothers receiving medications (group 1) and not taking any medications (group 2) N=30

		Pretest BP Mean± S.D.	Posttest BP Mean± S.D.	Mean Difference	t value	P value
Systolic BP	Group 1	149.23±4.47	142.06±7.48	7.17	5.17	<0.001**
	Group2	143.76±4.88	137.24± 8.66	6.51	4.29	<0.001**
Diastolic BP	Group 1	92.34±3.45	87.94±6.36	4.39	3.40	<0.001**
	Group2	91.06±4.257	86.06±4.40	4.00	5.52	<0.001**

Discussion

The present study was aimed to assess an effect of Audio assisted relaxation therapy on level of blood pressure among mothers with pregnancy induced hypertension. Findings of the study showed that AART was a safe method and helps to reduce systolic and diastolic BP and there was a positive strong correlation between AART and level of BP. So there is need to focus on use of non-pharmacological method to manage PIH and it can be implemented throughout the pregnancy.

Research studies conducted on effectiveness of interventions focusing on level of BP has shown to improve BP among mothers with PIH. A quasi experimental study was conducted at Government hospital and A.J Hospital, Mangalore in India in 2012 to evaluate the effectiveness of relaxation therapy on Mild Pregnancy Induced Hypertension. The results showed that the mean of pre-relaxation score (17.40) was significantly higher than the mean of post relaxation score (7.17). Since the difference in mean post therapy score is evident[13].A study was conducted to assess the effectiveness of guided imagery on level of blood pressure among PIH mothers in selected hospital in Pankajam Sitharam hospital at Trichy District, Tamilnadu 2015. A quantitative approach using quasi experimental pre-test post-test design with control group. Study sample is 60 PIH mothers were selected using Non-probability purposive sampling technique was used. Guided imagery was given to the mothers in experimental group for 10 minutes duration twice a day for 3 days. Sphygmomanometer was used to assess the level of blood pressure. Analysis using paired 't' test was obtained for level of blood pressure in control group was 0.84 which is not significant at p<0.05. For experimental group, the t value obtained was 22.52, which is highly significant at p<0.05 level. The findings of the study revealed that Guided Imagery helps in reducing blood pressure among PIH mothers[14]. In present study there was a significant difference in level of systolic and diastolic BP in pretest and posttest at level of 0.001.

So Audio assisted relaxation therapy can be used as an add on therapy for the management of mothers with pregnancy induced hypertension.

Conflict of Interest: The investigator has no conflict of interest.

Source of Funding: The study is funded by self.

Ethical Clearance: Ethical clearance was obtained from the institutional Ethics committee of Akal College of Nursing. Participation was based on willingness and written informed consent was obtainedfrom all participants.

Medical College (IGGMC), Nagpur, Maharashtra

Abstract

Introduction: Japanese encephalitis virus (JEV) belongs to Flavivirus group of viruses and is most important cause of Acute Encephalitis Syndrome (AES) in South East Asia. JEV has known to cause major epidemics in India leading to high mortality and morbidity. This study reports a seasonal outbreak of JEV in Central India.

Materials and Method: Serum samples were collected from patients and were processed by Ig M Capture ELISA (kit manufactured and supplied by NIV, Pune) as per the manufacturer's instructions. Vector surveillance was undertaken in the affected area and vector control measures were initiated.

Results: Among 28 samples, 15(53.57%) showed the presence of JEV antibodies. 86.6% paediatric population was affected. *Culex* density crossed critical level of 10%.

Conclusion: Vigilant role of microbiologist and rapid actions of public health workers can prevent JEoutbreaks and epidemics.

Keywords: *Japanese encephalitis, Seasonal outbreak, Vector surveillance.*

Introduction

Japanese encephalitis (JE) is a common mosquito borne flaviviral infection. It is one of the leading forms of viral encephalitis worldwide and is mostly prevalent in Southeast Asia, covering a population of over three billion.[1] Though all the age groups are vulnerable, predominantly it affects children (less than 14 years of age) in endemic regions. JE virus (JEV) infections mainly remain asymptomatic in humans, but 1% of infections result in clinical disease with a fatality rate of 20-30% and 30-50% of recovered patients may undergo everlasting neuropsychiatric sequelae. [2, 3] The ratio of overt disease to inapparent infection varies from 1:250 to 1:1000. Thus the cases of JE represent tip of the iceberg as compared to the large number of inapparent infections.[4] JE is said rarely to be mild and presents more often as frank encephalitis than do infections with other tropical flaviviruses.[5] Neurologic disease is the most prominent clinical feature of the systemic infection.[6]

The natural cycle of JEV in Asian continent involves water birds, *Culex* mosquitoes and an amplifying host. Humans and equines are considered to be the dead-end host since the viremia in peripheral blood is low and transient. *C.vishnui complex* act as a principal vector of JEV which breeds in water bodies with frank vegetation and spread in highest density between June and

Mob No.: 9021450574

November in temperate zones.[7] *Culex tritaeniorhynchus* is the most important and is associated with agricultural practices like rice cultivation or irrigated crop fields.[8] In Asia, pigs are considered to be the most important amplifying host, providing a link to humans through their close proximity to residential areas. Moreover, ardeid birds are considered responsible for the long-distance propagation of JEV and act as reservoir for the disease.[9]

In India, JE is a leading paediatric health issue and epidemics have been reported from many regions since 1955.[10] In recent past, India witnessed alarge outbreak in Malkangiri during 2012 and Manipur in July 2016.[11] Maharashtra is one of the most affected states along with some others in India.

The recommended method for laboratory confirmation of a JE infection is presence of JEV-specific Ig M antibody in a single sample of cerebrospinal fluid(CSF) or serum.The JEV-specific Ig M antibody capture ELISA has now become the first-line diagnostic assay recommended by WHO for detection of acute infections.[12]

The present study reports a seasonal outbreak of JEV with its epidemiological markers.

Materials and Method

The study was performed in Gadchiroli district in June-July 2018 which is highly maoist affected area located in east Maharashtra with a population of 1,072,942 (Population Census 2011-03-01).[13] JE and Dengue Ig M ELISA (kit manufactured by NIV, Pune) was done on all the samples as per manufacturer's instruction. The public health workers of the area assessed for presence of reservoir host such as pigs, cattle, poultry in the near vicinity of suspected cases. Vector surveillance was initiated immediately, that included collection of larvae and adult mosquitoes, identification of vector *species* and calculating their density. For adult vector collection, indoor and outdoor resting and dusk collection was carried out from fixed as well as random sites such as such as human dwelling, cattle sheds, mixed dwelling, bushes, plantations, standing crops, etc. by hand catch method using glass suction tubes. Per Man Hour Density (PMHD) was calculated.

PMHD = Number of mosquitoes collected

Actual man hours spent i.e. number of persons collecting X time spent in hours

For vector larvae,collection was done using dip method where the collecting equipment was immersed in the breeding places (edges of swamps, ditches, streams, rice fields other bodies of waters) at an angle of 45 º and larvae was collected. Larval density was calculated as –

Larval Density = [Total no. of larvae collected/Total no. of larval dips taken] × 100

Results

As Table 1 shows,out of total 28 serum samples tested for JE, 15(53.57%) showed the presence of JE Ig M and 4(14.28%) showed presence of dengue virus (DENV) Ig M. 3(10.71%) were positive for both JEV and DENV creating a diagnostic dilemma.

Table 1. Result of JE and Dengue Ig M ELISA

Sr.No.	Lab No.	Age in years	Sex	Result of JE Ig M	JE Ig M (Convalescent serum)	Dengue Ig M
1	75	14	Male	Positive		
2	76	14	Male	Positive		
3	77	40	Male	Equivocal		
4	79	12	Female	Equivocal		Negative
5	80	12	Female	Positive	Positive	Negative
6	81	12	Male	Positive	Positive	Negative
7	82	14	Male	Equivocal		Equivocal
8	83	14	Male	Negative		Negative
9	84	8	Female	Positive	Positive	Positive
10	85	13	Male	Positive	Positive	Equivocal
11	86	9	Female	Positive	Positive	Positive

Sr.No.	Lab No.	Age in years	Sex	Result of JE Ig M	JE Ig M (Convalescent serum)	Dengue Ig M
12	87	13	Female	Positive	Positive	Negative
13	88	13	Female	Positive	Positive	Equivocal
14	89	4	Female	Positive	Positive	Equivocal
15	90	32	Female	Equivocal		Equivocal
16	91	10	Female	Positive		Negative
17	92	10	Male	Equivocal		Equivocal
18	93	15	Male	Equivocal		Negative
19	94	28	Female	Positive		Negative
20	95	11	Male	Equivocal		Negative
21	96	10	Male	Equivocal		Negative
22	97	26	Female	Positive		Negative
23	98	5	Male	Positive	Positive	Positive
24	99	60	Male	Negative		Negative
25	100	6.5	Female	Negative		Negative
26	101	6	Male	Positive	Positive	Equivocal
27	102	14	Female	Negative		Positive
28	103	2.5	Female	Negative		Negative

Among positive, 6(40%) were male and 9(60%) were females. 13(86.6%) were children ≤ 14 years of age (lowest age was 4 years) and 2(13%) were adults less than 30 years of age. Maximum positivity was seen in age group of 4-6 and 7-9 years. Table 2 shows age wise distribution of positive cases.

Table 2. Agewise distribution of cases

Age group (in years)	No. of positive cases	Total no. of cases	% Positivity
1-3	0	1	0%
4-6	2	3	66%
7-9	2	3	66%
10-12	3	7	43%
13-15	5	9	55%
16-18	0	0	0%
>18 (adults)	2	5	40%

WHO says 'To confirm that a seasonal outbreak is due to JE, suspected cases should be tested until 5-10 are laboratory-confirmed as JE'[12] declaring this to be seasonal outbreak of JEV which was contained on a very primitive stage due to vigilant and active involvement of microbiologist leading to rapid actions as mentioned below taken by public health workers.

1. Insecticidal spray
2. Releasing guppy fishes
3. Mosquito net distribution
4. Educating people via mass meetings, handouts and posters
5. Checked for household water reservoirs and decant them if they had mosquito larva
6. Put tamifos in water bodies
7. Vector surveillance in and around the houses of confirmed and suspected cases. Results are shown in Table 3. It shows that only *Culexspecies* has density above the critical level of 10% beyond which epidemics are likely to occur.[14]

Table 3. Vector surveillance results

Vector Species	Density of adult (per man hour density)	Density of larva (per dip)
Anopheles culicifacies	5.2	108
Anopheles stephensi	0.0	
Anopheles fluventis	0.0	
Other Anopheles	7.2	
Aedesspecies	0.0	0.0
Culex quinquefasciatus	168	476
Culexvishnui	24	
Sandfly	0.0	0.0

Some confirmed cases were pig rearers having backside pigyards . Also, sudden increase in number of pond herons habitating near house of confirmed cases was noted.

Discussion

Out of 28,15(53.57%) showed the presence of JE specific antibodies in single serum specimen defining it as seasonal outbreak. In a study by Saikia L, 40.77 % were diagnosed as JE in patients of Acute Encephalitis Syndrome (AES).[15] Also, Anuradha SK showed 23.17% positivity for JE in viral encephalitis patients.[16] In a large outbreak in Uttar Pradesh, JEV was main viral etiology (49.4%) associated with AES cases applying serology.[17] Our positivity rate lies well in range as mentioned in other hospital based and outbreak studies.[18,19]

4(14.28%) showed presence of Dengue antibodies but in field surveys Aedes mosquito was not found. Absence of Aedes mosquito rule out the presence of dengue infection. There was also no history of travel in study patients. 3(10.71%) were positive for both JEV and DENV. Similar finding was demonstrated by Kaleshwar Prasad Singh *et. al.*[20]and other studies as well. [21,22] Presence of antibodies to both JE and dengue creates a diagnostic dilemma. In such cases, serological ratio of anti - dengue Ig M to anti- JE Ig M >1.1 defines infection with dengue virus, between 1.1 and <1.1 but >0.91 defines infection with unknown flavivirus and ≤ 0.91 defines a Japanese encephalitis virus infection .[23]In our study the ratio was≤ 0.91 and thus, these samples could be considered as JE positive increasing positivity to 64.28%.Nearly, similar positivity was noted in a large epidemic that took place in 16 districts of Uttar Pradesh, where 66.6% were positive for JEV.[24] Clinical presentation and other laboratory investigation can alsodifferentiate between JE and dengue infection.[25]

JE mostly affects children and is often referred to as "kid killer".[26] In our study, maximum positivity was seen in age group of 4-6 and 7-9 years. Similar findings are seen in a study by Auradha SK *et al.*[27]Epidemiological data collected from various JE endemic states of India during 2008–2013 also support our finding.[28]

About 25%–30% of JE cases are fatal and 50% result in permanent neuropsychiatric sequelae.[29]Case fatality rate (CFR) in our study is 7.14%which is low due to early detection and management of cases. The area specific case fatality rate ranged from 0 to 55.5% in the different districts or states during the period 1998 to 2002.[30]

Vector surveillance showed increased density of *Culexspecies* in the area showing need to do vector surveillance on routine basis and to watch for the early epidemiological warning signs. Other parameters like rainfall, rice field irrigation, migratory birds also affect transmission of JE and thus should be closely noted. Piggeries should be away from human residential areas as domestic pig rearing is an important risk factor in the transmission to humans.[31]Education plays an important role in preventing outbreaks of JE.[32]In our study also, different measures were taken to counsel and educate the population of the affected area where vector control and personal protective measures remained the mainstay.

Conclusion

This study reports the seasonal outbreak of JE in Central India which was contained at a very primitive stage due to vigilance of microbiologist and rapid actions taken by public health sector. AES caused by JE has high mortality and morbidity and due to early containment of the outbreak, this was prevented. Regular epidemiological surveillance is the key factor to prevent an epidemic.

Acknowledgment: We are thankful to DHR-ICMR,New Delhi for financial support and to NIV, Pune for their constant support and guidance. Thanks are also due to Asmita Babhulkar and Deepika Parise for their technical support and to public health workers from Gadchiroli district for their cooperation.

Conflicts of Interest: No conflicts of interest are associated with this study.

Ethical Clearance: Taken from Institute's ethical committee.

Source of Funding: DHR-ICMR, New Delhi.

A Study of Stress Level among Medical and Paramedical Students in Western Up India

Shivam Kamthan[1], Bhawana Pant[2], Deepak Kumar[3], Amit Mohan Varshney[4], Sartaj Ahmad[5], Arvind Kumar Shukla[6]

[1]Assistant Professor Instead of Tutor, Government Medical College Badaun, [2]Professor, [3]Assistant Professor, Department of Community Medicine, Subharti Medical College, Meerut, [4]Assistant Professor, Department of Community Medicine, MLB Medical College, Jhansi, [5]Associate Professor, (Medical Sociology), Department of Community Medicine, Subharti Medical College, [6]Assistant Professor, (Biostatistics), Department of Community Medicine, AIIMS, Raipur

Abstract

Introduction: Medical and paramedical students need high qualities of mental health as the education is highly stressful as compared to other professional modules. Minimal stress is sometimes subsidiary for a salubrious outwitting; high caliber of stress may have a negative effect on mastery of the academic curriculum and overall health.

Objectives: i. To assess the prevalence level of stress among medical and paramedical students. ii. To study the various factors associated with stress among medical and paramedical students.

Method: A cross-sectional-questionnaire based study was conducted among medical and paramedical students in Swami Vivekananda Subharti University, Meerut (U. P.). The stress was assessed by using Kessler 10-item psychological distress scale (K10) along with a pretested sociodemographic and preventive variables. Data were entered in Microsoft Excel and analyzed using SPSS version 19.0 statistical software. chi-square test was used

Results: In this study, it has been found that 59(21.6%) medical students were suffering from severe stress and 46(16.1%) paramedical students were suffering from severe stress. The female students had higher stress as compared to male students. The students of age >20 years had higher stress as compared to students of age <20 years. There was statistically lesser stress in students who practiced exercise and yoga daily as compared to students who did not practice exercise and yoga.

Conclusion: The medical students had higher severe stress as compared to paramedical students. The physical exercise and yoga were found to be very useful in prevention of stress among the students.

Keywords: *Stress, medical students, yoga, k10.*

Introduction

Medical and paramedical students need high qualities of mental health as the education is highly stressful as compared to other professional modules. Stress is stereotype in medical & paramedical students. Minimal stress is sometimes subsidiary for a salubrious outwitting; high caliber of stress may have a negative effect on mastery of the academic curriculum and overall health.[1]

Studying in university is one of the stressful stages of life and it is characterized by quite a bit of change in students lifestyles which is stress inducing. In

fact, the person experiences stressful events such as, changes in friendship relations, staying away from their home and family and education. In addition, studying medicine and Para medicine, by themselves, seem to be stressful due to their communication with patients, intensive curriculum and academic demands, including forced night awakenings for shifts and even for exam preparation .[2]

Medical & Paramedical education is highly stressful as compared to other professional curricula. Stress in medicos is not unorthodox and is process orientated. The enormous syllabus, peer competition for academic performance, perpetual evaluation and long duration of training are precipitating factors for stress s in medical & paramedical students.[3]

Stress is the condition that results when person-environment transactions lead the individual to perceive a discrepancy, whether real or not, between the demands of a situation and the resources of the person's biological, psychological or social system.[4]

Positive stress is called Eustress and Negative stress Distress. Eustress triggers the body alarm and enhances attention, performance and creativity; Distress has negative effects on the body impairing the person's physical and mental wellbeing. Different studies conducted worldwide among medical students have reported prevalence of stress ranging from 27-73%.[5]

There are ample academic stressors such as information receptivity overload, hectic routine that is devoid of socialization, minimal leisure time and recurrent academic evaluations. Some researches have shown that depression may lead to the state of fright, low motivation, despondency, anger and retaliation.[6] The continuous evaluation process, exhausting work hours, striving for earning high grades, goals etc. are not the only source of stress for medical students.[7,8]

The present study was undertaken to estimate the prevalence of psychological stress and association between the levels of stress and study variables among Subharti medical and paramedical students.

Aims and Objectives

I. To assess the prevalence level of stress among and paramedical students.

II. To study the various factors associated with stress among medical and paramedical students.

Material and Method

A cross sectional descriptive study was carried out at Swami Vivekananda Subharti University, Meerut (U. P.) from May 2017 to December 2018. Sample size was calculated using EPI INFO StatCalc, by using the following data; prevalence rate 50%, significance level 0.05 and power of the study 90%. Thus in this study, the minimum size was calculated as 270. Therefore, 273(medical) and 286(paramedical) students were randomly selected for the study. The sample was drawn from each semester of medical and paramedical undergraduate students of the university through systematic randomized sampling. The students who gave consent were included in the study and the students who were absent on the day of data collection were excluded from the study.

Study Tool: Data collection was performed by using the Kessler 10-item psychological distress scale (K10). It was designed to quantify current 4 weeks distress in population surveys. The K10 comprised of 10 questions. Each question scored on Likert scale ranging from 1to 5 The cut-off scores were used as < 20 no stress; 20–24 mild stress; 25–29 moderate stress; 30–50 rigorous stress[9-10]

Statistical Analysis*:* Data were entered in Microsoft Excel and analyzed using SPSS version 19.0 statistical software. Chi-square test was used to observe and quantify an association between the categorical outcome and different study variables. A p-value of < 0.05 was considered statistically significant.

Results

Table 1: Association of Demographic Variables of Medical Students & Paramedical Students and their stress level

Variables		Kessler Psychological Distress Scale (K10)								Total		P-Value
		Well		Mild		Moderate		Severe

1. In this study, 195(34.9%) students had no stress, 129(23%) students had mild stress, 130(23.2%) students had moderate stress and 105(18.8%) students had severe stress.
2. 219 (39.2%) of students were <20 years of age and 340 (60.8%) were> 20 years of age. A proportion of 70 (54.3%) mild, 60 (46.2%) moderate and 34 (32.4%) severe stress was found in < 20 years of age. 59 (45.7%) mild, 70 (53.8%) moderate and 71 (67.6%) severe stress was found in >20 years of age. There was statistically significant difference between the age group.
3. Gender wise distribution was found as 265 (47.4%) of students were males and 294 (52.6%) were females. A higher proportion of female students were found. 76 (58.9%) mild, 75 (57.7%) moderate and 60 (57.1%) severe stress was measured. Among male students 53 (41.1%) mild, 55 (42.3%) moderate and 45 (42.9%) severe stress was found in this study. There was statistically significant difference between the genders.
4. 138 (24.7%) of students belongs to rural community and remaining 421 (75.3%) belongs to urban area. 101 (78.3%) mild, 97 (74.6%) moderate and 72 (68.6%) severe stress was found in urban respondents. 28 (21.7%) mild, 33 (25.4%) moderate and 45 (42.9%) severe stress was found in rural respondents. There was not statistically significant between the residences of students.
5. 453 (81.0%) of students were Hindus and 91 (16.3%) were Muslim by the religion. 96 (74.4%) mild, 112 (86.2%) moderate and 89 (84.8%) severe stress was found among Hindu respondents. 31 (24.0%) mild, 16 (12.3%) moderate and 13 (12.4%) severe stress was found among Muslims. There was not statistically significant between the religions.

Table 2: Comparison of stress among medical and paramedical students

Variables	Kessler Psychological Distress Scale (K10)								Total		P-Value
	Well		Mild		Moderate		Severe				
	FREQ	%	FREQ	%	FREQ	%	FREQ	%	FREQ	%	
Medical	121	44.3	45	16.5	48	17.6	59	21.6	273	100	<0.001
Paramedical	74	25.9	84	29.4	82	28.6	46	16.1	286	100	Sig.

In this study, it has been found that 45(16.5) had mild stress, 48 (17.6%) moderate stress and 59(21.6%) medical students were suffering from severe stress. 84(29.4%)had mild stress,82(28.6%) moderate stress and 46(16.1%) paramedical students were suffering from severe stress .The results were found to be statistically significant.

Table 3: The association of addiction and stress level of study subjects.

Variables		Kessler Psychological Distress Scale (K10)								Total		P-Value
		Well		Mild		Moderate		Severe				
		Freq	%	Freq	%	Freq	%	Freq	%	Freq	%	
Smoke	No	186	95.4	125	96.9	126	96.9	102	97.1	539	96.4	0.814
	Yes	9	4.6	4	3.1	4	3.1	3	2.9	20	3.6	
Alcohol	No	194	99.5	127	98.4	128	98.5	105	100.0	554	99.1	0.475
	Yes	1	0.5	2	1.6	2	1.5	0	0.0	5	0.9	

Only 20 (3.6%) of respondent were ever smokers, out of them 4(3.1%) mild, 4(3.1%) moderate and 03(2.9%) severe stress was found in ever smoker, although 2(1.6%)mild, 2(1.6%)mild, 2(1.5%) moderate was found in alcoholic respondents. There was no statistically significant association.

Table 4: The association of exercise or pray with stress level of study subjects.

		Kessler Psychological Distress Scale (K10)								Total		P-Value
		Well		Mild		Moderate		Severe				
		Freq	%	Freq	%	Freq	%	Freq	%	Freq	%	
Exercise/ Yoga	No	79	40.5	46	35.7	50	38.5	61	58.1	236	42.2	0.003
	Yes	116	59.5	83	64.3	80	61.5	44	41.9	323	57.8	
Pray	No	7	3.6	5	3.9	5	3.8	3	2.9	20	3.6	0.975
	Yes	188	96.4	124	96.1	125	96.2	102	97.1	539	96.4	

323 (57.8%) of students were engaged in physical activities such as exercise and yoga. Out of them, 83 (64.3%) mild, 80 (61.5%) moderate and 44 (41.9%) severe stress was found in active students. There was statistically significant association present.

539 (96.41%) of respondents did prayer regularly. Out of them, 124(96.1%) mild, 125 (96.2%) moderate and 102 (97.1%) severe stress was found in respondent who did prayer regularly. There was no statistically significant association present.

Discussion

The present study found out that students suffering from severe stress was more in medical (21.6%) compared to paramedical students (16.1%) and it was found to be statistically significant. The academic burden and competition of postgraduate seats might have caused much severe stress in medical students as compared to paramedical students. Singh A and Singh S (2008)[9], Moayedi et al (2016)[2] found prevalence of perceived stress seems to be high among medical students. The study by Shapiro SL et al (2007)[10] also had documented high ratio of substance abuse interpersonal relationship problems, stress, depression and anxiety among medical students. The same study also reported that lack of social support, loneliness, specific personality factors and poor emotional adjustment of the professional students caused high stress in medical and paramedical students.

In our study it was seen that girls had more stress as compared to boys. A recent research reported similar findings by Mohsin S. et al. (2010)[11] that the overall mean perceived stress was significantly higher among female students but with the contrast that stress was not found

to differ significantly on the basis of sex as reported by Supe AN (1998)[12]. In fact, the literature revealed inconsistent data about gender difference and stress. The inconsistency in the data might be due to the reason that stress is itself a manifestation of multiple factors like biological, sociocultural or variable combinations of each.

In our study, students were >20 years of age had signicantly more stress as compared to students <20 years. The high stress in students >20 years might also be due to higher academic burden and competition for the postgraduate seats. Similarly, Yousif W (2016)[13] showed a significant association between stress and student age more than > 20 years.

The students living in urban area (68.6%) were seen to be suffering from severe stress compared to rural students (31.4%) which not found to be statistically significant. There was no significant association was observed between dietary pattern and stress. Also there was no significant relation found between stress and habits like smoking and alcohol.

323(57.8%) of students were engaged in physical activities such as exercise and yoga. The present study showed that exercise & yoga including physical postures, breathing exercises and meditation may be effective in reducing stress levels In a study done by Lona Prasad et al (2016)[14], yoga and exercise showed a statistically significant reduction in perceived stress. Andrée-Anne Simard & Melissa Henry (2009)[15] reported that the students reported improvements in overall health, perceived stress and depressive symptoms following the yoga intervention. Ms. Christine Michael (2017)[16] reported the stress among nursing students decreased with the practice of Yoga Nidra[17].

Conclusion

The medical students had higher severe stress as compared to paramedical students. The female students had higher stress as compared to male students. The stress level of students increased with age and academic year of curriculum. The higher level of stress among medical and paramedical students might be due to high academic burden during the studies. The physical exercise and yoga were found to be very useful in prevention of stress among the students. Therefore, it is recommended that the physical exercise and yoga should be used as preventive strategies of stress among medical and paramedical students.

Influence of Chair Based Exercises on Quality of Life among Frail Elderly

Shreeya Dilip Berde[1], Shrinivasan Anandh[2]

[1]Intern, Faculty of Physiotherapy, [2]Professor, Department of Community Health Sciences, Faculty of Physiotherapy, KIMS "Deemed to be University", Karad, Maharashtra, India

Abstract

Frailty, a progressive physiologic decline in multiple body systems, marked by loss of function, loss of physiologic reserve and increased vulnerability to disease and death. The overall prevalence of frailty is 22.7%. Frailty is more common in women (25.3%) than in men (18.6%).[1] Exercise has a wide range of health benefits in older people.[2,3] Mostly for community-dwelling population there is a clear evidence to support exercise in improving health and quality of life with well evidenced exercise programs. These programs have shown to reduce the risk of falls with associated benefits on mortality, morbidity and costs to health and social care.[5,6]Frail elderly people are often unable to undertake high intensity exercise programmes.[7] Therefore chair based exercises are been used as an alternative. Many research studies have reported the benefits of chair based exercises as a physical activity for older adults and individuals with limited movement.[4]

Method: The subjects in the KIMSDU campus were screened and 42 subjects fulfilling the criteria were involved. Prior consent was taken. Treatment protocol consists of chair based exercises for 4 days per week for 6 weeks The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of QOL and 6MWT.

Result: Intra group comparison results showed that chair based exercises are effective and QOL and 6MWT were statistically significant ($p<0.0001$) and (0.0431) respectively.

Conclusion: Chair based exercises were significantly effective in improving the mobility and function and preventing the risk of falls among frail elderly population.

Keywords: *Frail elderly, Chair based exercises, Quality of Life questionnaire (SF-36), 6 Minute Walk Test.*

Introduction

Frailty, a progressive physiologic decline in multiple body systems, marked by loss of function, loss of physiologic reserve and increased vulnerability to disease and death. With increase in age the prevalence of frailty increases. The overall prevalence of frailty is 22.7%. Frailty is more common in women (25.3%) than in men (18.6%).[1] Exercise has a variety of health benefits in older people.[2,3] Physical activity is the single most beneficial thing that individuals can do to maintain their health and function and quality of life.[4] Mostly for elderly population there is a clear evidence to support exercise in improving health and quality of life with well evidenced exercise programs widely engaged in clinical practice. These programs have shown to reduce the risk of falls with associated benefits on mortality, morbidity and costs to health and social care.[5,6]

Frail elderly people are often unable to undertake high intensity exercise programmes.[7] Therefore chair based exercises are been used as an alternative. Many research studies have reported the benefits of chair based exercises as a physical activity for older adults and individuals with limited movement.[4]

Research in the general population has shown that the elderly population who took part in regular, moderate chair based exercises have experienced increase in stamina and energy to do work than who doesn't. Chair based exercises increases the release of endorphins by the brain which raise the pain threshold and thus helps to increases the endurance. Chair based exercises is a modified form of exercises which mainly works upon the musculoskeletal and cardiovascular fitness of an individual.

Chair based exercises have been shown to have a beneficial effect at maintaining or promoting independence and mobility in older people.[8] The range of improvements demonstrated in research trials, lasting 8 weeks or longer, considering chair-based seated and chair-assisted standing exercises in both community dwelling and frail institutionalized older people include:[8]

- ↑Strength[9]
- ↑Power[10]
- ↑Flexibility[11]
- ↑Ability to perform everyday tasks[12]
- ↑Balance[9]
- ↓Depression[10]
- ↓Body fat[13]
- ↓Arthritic pain[14]
- ↓Postural hypotension[15]
- ↓Risk of falls[16]
- ↑ Reaction time
- ↓Stress and anxiety

Compliance to chair based programs is generally better than that of standing or dynamic exercise, especially amongst the oldest old and amongst those with low baseline levels of fitness and function. Chair based exercise has specific benefits as a training method.[17]

- It stabilises the lower spine by providing a fixed base (particularly important in those with kyphosis or lordosis of the spine).
- It facilitates greater range of movement by providing points of leverage and support.
- It minimises load-bearing and reduces balance problems in those with particularly poor mobility and arthritic pain.
- It increases confidence in those unable to perform free-standing exercise.[17]

Although chair based exercise has been shown to be effective, it should, in principle, be a starting point for those with low baseline function and be a part of a fuller rejuvenation/rehabilitation process. Ideally, for full preservation of independence, a programme that moves on, in time, to standing and to more dynamic challenges will better preserve gait, balance and mobility which intend may help to improve the quality of life.[17]

The chair based exercises are as follows:[18]

1. Marching
2. Knee Lift
3. Half Jack
4. Criss-Cross (along with arm movement)
5. Single Knee Raise
6. Mambo
7. Side Kick
8. Back Kick
9. Squat
10. Side Step
11. Swing

It is found in earlier studies that physical activities improve the metabolism and blood circulation. However there is limited research available to show any significant impact of chair based exercises on quality of life among frail elderly.

Materials and Methodology

An approval for the study was obtained from the Protocol committee and institutional Ethical Committee of Krishna Institute of Medical Sciences Deemed To be University. The subjects in Krishna Institute of Medical Sciences Deemed To be University campus were screened and those fulfilling the inclusion and exclusion criteria were involved. Participants were informed about

the study and consent was taken. Pre-test assessment was taken by using Quality of life questionnaire (SF-36) and 6 Minute Walk Test.[19] Chair Based Exercises was then given as per the protocol for 4 days per week for 6 weeks. Post-test assessment was taken by using Quality of life questionnaire (SF-36) and 6 Minute Walk Test. The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of Quality of life questionnaire (SF-36) and 6 Minute Walk Test.

Chair Based Exercise Protocol:[20,21]

1. **Warm UP** (6 minutes),
   - Heel digs
   - Side to touch
   - Back to touch
   - Knee raise
   - Punches
   - Trunk twist

   Each move will have 20 repetitions.
2. **Workout** (18 minutes)
   - (Sitting Position)
     - Marching
     - Knee lift
     - Half jack
     - Criss cross
     - Single knee raise
     - Mambo
   - Standing Position
     - Side kick
     - Back kick
     - Squat
     - Side step
     - Swing
   - Sitting Position
     - Marching
     - Knee lift
     - Half jack
     - Criss cross
     - Single knee raise
     - Mambo

   Each move will have 20 repetitions.
- **Cool Down** (6 minutes)
  - Hamstring stretch
  - Adductor stretch
  - Trunk side flexor stretch
  - Triceps stretch
  - Pectoral stretch

  Each stretch will be held for 20 seconds.

This protocol will be conducted for 4 days in a week for 6 weeks.

Statistical Analysis: Statistical analysis was done manually and by using the statistics software's INSTAT so as to verify the results derived. The statistical analysis of parametric data was done by using paired t test. Paired t test was used for statistical analysis of pre and post intervention within the group.

Results

1. Age Distribution

Table 1: Age distribution

Age Group	No. of Individuals
60-64 yrs	8
65-69 yrs	22
70-74 yrs	12

2. Gender Distribution

Table 2: Gender distribution

Gender	No. of Individuals
Male	25
Female	17

3. Outcome Measures

(6 Minute Walk Test and Quality of Life)

Table 3: Comparison of pre and post 6MWT and QOL within the group

Outcome Measures	Pre-test	Post-test	P value	t value	Inference
6 MWT	286±27.57	298±23.91	0.0431	2.055	Significant
QOL	56.14±6.561	60.23±6.199	0.0001	30.222	Extremely Significant

In present study the pre-test mean of 6MWT was 286±27.57, whereas post-test mean was 298±23.91. The pre-test mean of QOL was 56.14±6.561, whereas post-test mean was 60.23±6.199. Intra group analysis of 6MWT and QOL revealed statistically increase in post-test 6MWT and QOL scores. This was done by using paired t test. 6MWT (P=0.0431), QOL (P<0.0001).

Discussion

Frailty is often clinically apparent to geriatricians, especially in its end stages. Frailty, a progressive physiologic decline in multiple body systems, marked by loss of function, loss of physiologic reserve and increased vulnerability to disease and death. Frailty increases susceptibility to acute illness, falls, disability, institutionalization and death. The prevalence of frailty increased with age in men and women. The overall prevalence of frailty is 22.7%. Frailty is more common in women (25.3%) than in men (18.6%).[4] Exercise has a wide range of health benefits in older people.[5,6] Physical activity is the single most useful thing that individuals can do to maintain their health and function and quality of life.[7] Mostly for community-dwelling population there is a clear evidence to support exercise in improving health and quality of life with well evidenced exercise programs widely employed in clinical practice. These programs have shown to reduce the risk of falls with associated benefits on mortality, morbidity and costs to health and social care.[8,9]The present study "Influence of chair based exercises on quality of life among frail elderly" was conducted to see the effects of chair based exercises on quality of life among frail elderly.

The objectives of this study were to assess pre-test and post test measures of frail elderly using Quality of life questionnaire (SF 36) and 6 Minute Walk Test. To decrease the risk of falls and increase the ability to perform everyday in frail elderly population. To maintain their functional status, reduce the postural stress and to promote safe exercises. To specify the beneficial and harmful effects as per individual performance. To motivate repetitive movements with confidence and perform it regularly without supervision. This study has been designed to assess the influence of chair based exercise on mobility and function among frail elderly.

The study was conducted with 42 subjects. The subjects in the KIMSDU campus were screened and those fulfilling the criteria were involved. Subjects were informed about the study and prior consent was taken. The treatment protocol was carried out for 4 days in a week for 6 weeks. The outcome measures for this study were Quality of life questionnaire (SF-36) and 6 Minute Walk Test.

The results of this study showed that there was a significant difference in improving the mobility and function of frail elderly population after 6 weeks of intervention by giving chair based exercises.

Paired t test was used to analyze the influence of chair based exercises on quality of life among frail elderly and showed that there was significant improvement in mobility and function in frail elderly according to the 6MWT score (p=0.0431) and QOL questionnaire score (p<0.0001).Research in the general population has shown that the elderly population who took part in regular, moderate chair based exercises have experienced increase in stamina and energy to do work than who doesn't. Chair based exercises increases the release of endorphins by the brain which raise the pain threshold and thus helps to increases the endurance. Chair based exercises is a modified form of exercises which mainly works upon the musculoskeletal and cardiovascular fitness of an individual. Physical activity is the single most useful thing that individuals can do to maintain their health and function and quality of life.[4]Mostly for community-dwelling population there is a clear evidence to support exercise in improving health and quality of life with well evidenced exercise programs widely employed in clinical practice. These programs have shown to reduce the risk of falls with associated benefits on mortality, morbidity and costs to health and social care.[8,9]Chair based exercises have been shown to have a beneficial effect at maintaining or promoting independence and mobility in older people. Compliance to chair based programs is generally better than that of

standing or dynamic exercise, especially amongst the oldest old and amongst those with low baseline levels of fitness and function.[22]

Therefore the result of present study showed that chair based exercises intervention was significantly effective on improving the quality of life among frail elderly population.

Conclusion

Chair based exercises were significantly effective in improving the mobility and function and preventing the risk of falls among frail elderly population.

Abstract

Background and Purpose: In stroke, there is paralysis or weakness of one side of the body including upper limb, trunk and lower limb leading to the disturbances in the trunk muscles. Trunk is often neglected part in the stroke rehabilitation, trunk training exercises and Swiss ball exercises results in better recruitment of trunk muscles thus improving sitting balance. Core strengthening is said to be essential for balance and independent ambulation but it often been omitted in stroke rehabilitation.

Objective: To compare the effect of core strengthening exercises on Swiss ball and Mat, to improve trunk balance in hemiplegic patients following stroke.

Material and Method: A total number of 70 subjects were screened as per inclusion and exclusion criteria. The subjects were divided into two groups, Group-A received core strengthening exercises on Swiss ball along with conventional treatment and Group-B received core strengthening exercises on Mat along with conventional treatment. Treatment session was done 5 days a week for 6 weeks for 45-60 minutes. Pre and Post evaluation was done on the basis of Trunk impairment scale (TIS) score, Brunel balance assessment (BBA)score and Modified Barthel Index (MBI). **Results:** Subjects showed improvement in trunk balance following 6 weeks of core strengthening exercises. Post-intervention the TIS, BBA and MBI score of both groups improved but the Group-A improved more significantly than Group-B. The level of significance was P<0. 0001.

Conclusion: This study concluded that both the interventions have improved the trunk balance and activity of daily living by making the patient functionally independent.

Keywords: *Stroke, Swiss ball, Core strengthening, Trunk balance, Mat.*

Introduction

The "American Heart Association/American Stroke Association"(2016), stated that on a normal, in every 3 minutes 42 seconds, somebody dies of stroke.(1) World Health Organization (WHO) defined stroke as: "rapidly developing clinical signs of focal (or global) disturbance of cerebral function, with symptoms lasting 24 hours or longer or leading to death, with no apparent cause other than of vascular origin".(2) Among the non-communicable illnesses as assessed by Indian council of medical research, mortality rate is resulted in 41% cases and differently-abled is observed in 72% of stroke.(3) Throughout the United States, roughly 1 of each 19 expiries(1) and more than 7,95,000 individuals consistently experience the ill effects of a stroke.(4) The trunk muscles are impaired on both ipsilateral and contra lateral side of body to that of site of lesion, because the trunk muscles of the two sides of the body functions in synchrony.(5) The back extensors and the abdominal muscles are the two group of muscles which

are essentially important for moving and controlling the trunk.[6] The pelvic movement originates from trunk muscles, as pelvis is a part of trunk that supports further extremity movements.[7]

Balance is defined as the ability to maintain functional equilibrium.[8]Balance is a complex process which includes the integration and reception of sensory inputs and,[5] the visual, proprioceptive and vestibular system, along with the central functions of planning and execution of movement.[9]Anticipatory postural adjustments (APA) predicts the level of balance impairment and related danger of mobility as well as falls and are significant neuromuscular biomarkers.[10]

Core stability is regarded as recovery of balance after perturbation, by utilizing the capability of the lumbo-pelvic-hip complex to prevent buckling of the vertebral column.[11] A "core" comprising of the abdominals anteriorly, backside gluteal and paraspinal muscles, diaphragm as the roof and hip girdle and pelvic floor muscles at the bottom, is referred as box. [12] Bergmark (1989) [13] had differentiated the muscles as "local" muscles and "global" muscles, on the basis of the activity on the lumbosacral spine. The local muscles are actively involved in segmental stability of trunk, whereas the global muscles modulate the spine and trunk movement.[14]

Swiss ball (physio ball), also known as Pezzi ball, was created in 1963 by Aquilinocosani, an Italian plastic manufacturer [15].Before testing the patient's balance on the Swiss ball, the balance during static and dynamic condition is checked on a rigid and steady support in sitting and standing posture. [16]

The **Mat** program includes the patient in exercises that combines both movement and stability. [17] Functional exercises on mats are planned dynamically for improving the patient's independence. [18]

As a primary and secondary outcome measures, the results are estimated for the control of trunk by using the Trunk Impairment Scale (TIS) and the Brunel Balance Assessment (BBA) and Modified Barthel Index (MBI) for assessing functional balance after the stroke.

Methodology

Method: The study was conducted after taking approval from the institutional research ethics committee, approval no. (DMIMS(DU)/IEC/2018-19/7197) in Department of Neuro Physiotherapy, Ravi Nair Physiotherapy College, Acharya Vinoba Bhave Rural Hospital, Sawangi (Meghe), Wardha. Inclusion criteria were patients suffered from first episode of stroke within 1-3 months of duration, age between 40 to 60 years, stage 2, on the Modified Ashworth Scale, no visual and sensory deficits, ability to communicate verbally. Exclusion criteria were the existence of any other neurological or orthopaedic diseases, haemorrhagic stroke, patients having cognitive problems. of each of the 70 subjects composed pre informed consent, marked or with thumb impression was taken toand they were told about the conceivable result of the intercessions. Pre and post TIS score, BBA score and MBI score was taken. Patients were distributed in two groups with 35 subjects in each group respectively and were chosen randomly.

Subjects in a Group-A received core strengthening exercise on Swiss ball along with conventional treatment and subjects in the Group-B received core strengthening exercise on Mat along with conventional treatment. The total duration of exercises was almost approximately, 45 minutes to one hour. Subjects have permitted to take rest for 2 minutes in the middle of each new exercise or as and when he/she wished. Also, for core strengthening the patient had to asked to draw-in the abdominal muscles for 5 counts or 5 seconds.

Conventional physiotherapy- was received for 15 minutes by the both groups which includes, Active assisted range of motion exercise of upper limb (15 times each movement)-Shoulder, Elbow and Wrist and finger range of motion exercise.

Lower limb(15 times each movement)-Hip, knee and ankle range of motion exercise.

Core strengthening exercises on Swiss ball (GROUP-A) was given in supine-lying position,with upper trunk flexion and with lateral upper trunk flexion.

Interventional exercise (GROUP-A):

Supine-lying exercises: Bridging, Unilateral Bridging, Lower trunk rotations.

Sitting exercises: Static sitting balance, Forward trunk flexion, Lateral trunk flexion, Trunk rotations in sitting, Weight shifts, Forward reach, Lateral reach, Perturbations, sit to stand.

Core strengthening exercises on Mat (Group-B): Supine-lying position- Core strengthening exercise on

Mat was done in crook lying position, Upper trunk in flexion, Upper trunk diagonal rotation.

Common mat activities: Rolling-From the Supine-lying to Prone-lying: Flexion/abduction pattern of upper-limb, Flexion/abduction pattern of lower-limb.

From Prone-lying to Supine-lying-Flexion/ abduction pattern of upper limb to roll from prone-lying to supine- lying.

Bridging, Unilateral pelvic bridging, Upper trunk rotation, Lower trunk rotation, Prone on elbow, Quadruped position, kneel sitting, Kneel standing, Half kneeling.

Data Analysis: Statistical analysis was done by using descriptive and inferential statistics using chi square test, Wilcoxon Signed Rank Test and Mann Whitney U test as well as SPSS version 22.0 and Graph Pad Prism 7.0 version. The $p<0.05$ is considered as level of significance.

Table 1: Comparison of mean difference in Total Trunk Impairment Scale Score in Group A and Group B

Mann Whitney U Test:

Group	N	Mean	Std. Deviation	Std. Error Mean	z-value
Group A	35	10.71	0.57	0.09	4.83 P=0.0001, S
Group B	35	9.77	1.00	0.16	

According to table 1, based on Mann Whitney U test, the mean difference of total Trunk Impairment Scale score in Group-A and Group-B was compared. The P value was 0.0001 ($P<0.05$), which was found to be significant and represented graphically.

Table 2: Comparison of mean difference in Brunel Balance Assessment Scale at 1 week and at 1 month in Group A and Group B

Mann Whitney U Test:

	Group	N	Mean	Std. Deviation	Std. Error Mean	z-value
1 week	Group A	35	0.37	0.49	0.08	0.49 P=0.62,NS
	Group B	35	0.31	0.47	0.07	
1 month	Group A	35	4.88	0.58	0.09	10.47 P=0.0001, S
	Group B	35	3.40	0.60	0.10	

According to table 2, based on Mann Whitney U test, the mean difference of Brunel Balance Assessment Scale in Group-A and Group-B was compared at 1 week and 1 month. The P value was 0.62 ($P>0.0001$), which is found to be non-significant at 1 week in both groups respectively while the P value 0.0001($P<0.05$) was found at 1 month which was found to be significant and represented graphically.

Table 3: Comparison of mean difference in Modified Barthel Index Score in Group A and Group B

Mann Whitney U Test:

Group	N	Mean	Std. Deviation	Std. Error Mean	z-value
Group A	35	11.65	0.59	0.09	8.64 P=0.0001, S
Group B	35	9.65	1.23	0.20	

According to table 3, based on Mann Whitney U test, the mean difference of Modified Barthel Index score in Group-A and Group-B was compared. The P value was 0.0001 ($P<0.05$), which was found to be significant and represented graphically.

Discussion

Regain of the trunk balance or proximal and distal stabilization is an important part of stroke rehabilitation, as trunk balance is related with a marked improvement of functional activity of daily living.[19] Usually, the functional exercises of everyday living require the co-ordination between the limb and the trunk. The goal of the current study was to analyze the impact of Swiss ball exercises and Mat exercises combined with conventional treatment for increasing the strength of core muscles to improve trunk balance in subacute stroke patients.

Static sitting balance assesses the capacity to sit upright in sitting position within the normal base of support or when the base of support has been decreased. Results indicated noteworthy improvement in the two groups following intervention. The mean pretest score was improved from 5.51 to 7.00 following 6 weeks of treatment in Group-A while the Group-B improved from 5.65 pretest score to 7.00 post test score following intervention which was significant. Anyhow, when we correlate the mean difference in static sitting balance in Group-A and Group-B with the mean values of 1.48 and 1.34, there was no significant change found, P value was 0.22. The dynamic sitting balance domain assesses

specific side flexion of upper and the lower part of trunk. Over a 6 week's time of treatment, the mean pre and post test scores of the dynamic sitting balance domain of TIS in the Group-A enhanced from 4.77 to 9.94 while the Group- B improved from 4.91 to 10.00. But, when we compared the mean difference in dynamic sitting balance in Group- A and Group- B with the average values was 5.17 and 5.08, which shows that there was no significant difference found. The co-ordination domain of TIS assesses the upper and lower trunk rotations independently and checks for the symmetry in the rotations. Following intervention mean score of co-ordination in the Group-A improved from 2.00 to 6.00 and 1.88 to 5.22 in Group- B and after comparing the average difference of co-ordination scores in Group-A and Group-B with the mean values of 4.00 and 3.34, a significant enhancement was found in two groups, P value was less than 0.05.

Following a month of intervention, the mean pretest and post test scores of BBA at baseline evaluation, one-week evaluation and following 1 month of evaluation changed from 5.62 to 6.00 and 10.51 respectively in Group-A and from 5.48 to 5.80 and 8.88 in Group-B. However, by comparing the mean difference of BBA at one week and one month we found that the mean values were increased from 0.37 to 4.88 in Group-A and 0.31 to 3.40 in Group-B respectively.

Significant improvement of Modified Barthel Index scores in both the groups might be because of the common conventional treatment which was given to both the groups. Average pre-test grade of Modified Barthel Index in Group-A and Group-B was 6.05 and 6.41. Following 6 week of treatment program the average post-test grade in Group-A and Group-B stood 17.71 and 15.80, which was found to be significant. Also, when we compare the mean difference in Modified Barthel Index score in Group-A and Group-B which was 11.65 and 9.65 respectively.

Conclusion

This study concluded that both the interventions have improved the trunk balance and activity of daily living by making the patient functionally independent.

A Study to Aseess the Level of Knowledge on Diabetic Diet among Diabetic Patients in Selected Villages, Kanchipuram District, Tamil Nadu, India

Sowmya Sabu[1], Yaga Jeyanthi M.[2], Bhuvaneshwari[1], Divyapriya[1], Thatchayani[1], Lini Thomas[1], Padma Ramya[1]

[1]B.Sc.(N) IV Yr, [2]Associate Professor, Chettinad College of Nursing, Chettinad Academy of Research and Education Kelambakkam, Kanchipuram District, Tamilnadu, India

Abstract

Diabetic diet is one of the best tool for managing diabetes. It is a healthy eating plan that's naturally rich in nutrients and low in fat and calories. The study topic is A study to assess the knowledge on diabetic diet among diabetic patients in selected village, Kancheepuram District, Tamil Nadu. The objectives of this study are to assess the knowledge on diabetic diet among diabetic patients and to associate the knowledge on diabetic diet among diabetic patients with selected demographic variables. The sampling technique used was simple random sampling technique with the sample size of 50 diabetic patients. An extensive review of literature with the guidance of experts formed the foundation to the development of questionnaires. Structured interview schedule was used to assess the knowledge on diabtetic diet. The collected data was tabulated and analyzed by using descriptive and Chi-squire test. The study shows that the diabetic patients have inadequate (26%), moderate (24%) and adequate (50%) knowledge on diabetic diet. Hence health education was given for the diabetic patients with inadequate and moderate knowledge score to improve the patient knowledge. There is a significant relationship between selected demographic variable such as sex, income, duration of disease and family history of diabetes mellitus withe their knowledge.

Keywords: *Assess, knowledge, diabetic diet, diabetic patients.*

Introduction

Hasnain S (2013) .A diabetic diet is a dietary pattern that is used by people with diabetesor high blood glucose to manage diabetes. Adiabetic diet is the best eating plan for most everyone. More modern history of the diabetic diet may begin with Frederick Madison Allen and Elliott Joslin, who, in the early 20th century, before insulin was discovered, recommended that people with diabetes eat only a low-calorie and nearly zero-carbohydrate diet to prevent ketoacidosis from killing them. While this approach could extend life by a limited period, patients developed a variety of other medical problems. The introduction of insulin by Frederick Banting in 2015 allowed patients more flexibility in their eating. [1]

Reader DM (2014) viewed that diet has been the mainstay of therapy in diabetes for centuries. A number of factors influence glycemic response to food, including the amount of carbohydrate, type of sugar, nature of starch, cooking and food processing and food structure as well as other food components that slow digestion-lections, phytates, tannins, starch protein and starch lipid.[2]

Need for the Study: A cross sectional study conducted among 155 diabetic mellitus patients to assess knowledge, attitude and practice of dietery pattern.

Corresponding Author:

e-mail: yagajeyanthi@gmail.com

Samples were selected from the out patient department, primary health centre. The study result shows the majority of the patients did not followed diabtic diet (56%) and only 15% were followed the therapeutic diet regimenn. The majority of the patients took only 1-2 serving of starch and less than one serving of fruits per day and 41% of patients drank only four cups of water per day. [3]

A study was conducted in 2017 to assess the knowledge and practice of type 2 diabtes mellitus patients among 33 diabetec patients for the period of three months. The sample HbA1c result has also considered to assess micro and macro vascular complications. In developing countries the success of management of diabetes mellitus requires the health professionals should orient about the cultural beliefs, family & communal networks of the patients. The patients should also have good knowledge about the disease and diet. [4]

Objectives of the Study:

- To assess the knowledge on diabetic diet among diabetic patients
- To associate the knowledge on diabetic diet among diabetic patients with selected demographic variables.

Methodology

Research Approach: Non experimental-Quantitative Research Approach.

Research Design: Descriptive research design .

Research Setting: The study was conducted in selected village- Perumaleri, Kanchipuram district

Sampling Technique: Simple random sampling technique

Sampling Size: 50 diabetic patients

Sampling Criteria:

Inclusion Criteria:

- Patients with Diabetes Mellitus (Diagnosed patients)
- Patients who are willing to participate

Exclusion Criteria:

- Patients with elevated blood glucose (Un-diagnosed patients)
- Diabetic patients who are not present at the time of the study

Development and Description of the Tool: The tool was developed by the researcher on reviewing literature and in consultation with nursing experts in the field of community medicine and nursing.

Description of the Tool:

The tool consist of two sections: Section A: Demographic variables such as age, sex, education, monthly income, dietary habits, duration of diabetes mellitus and family history of diabetes mellitus

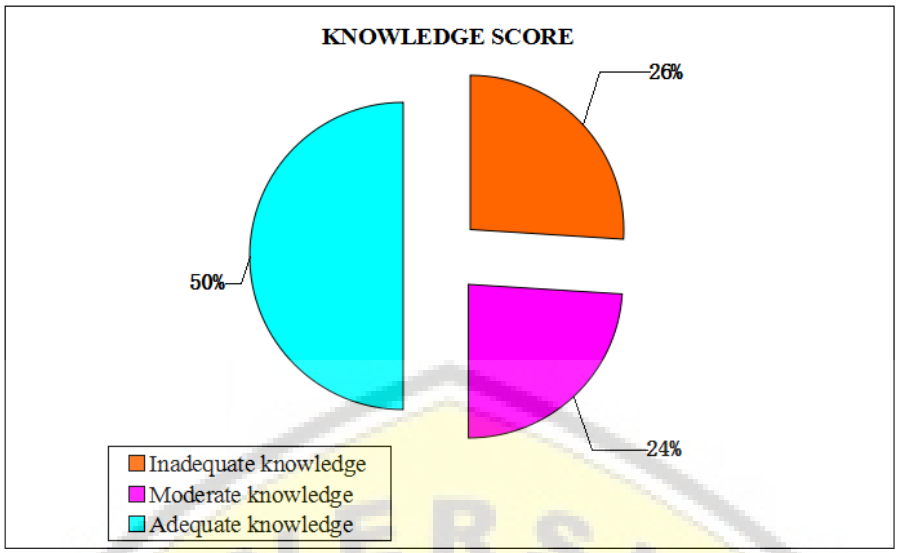
Section B: Questionnaire to assess the level of knowledge on diabetic diet among diabetic patients

Method of Scoring and Interpretation: Tool consist of 15 questions. Right response was given 1 score. Wrong response was given 0 score. 0-5 knowledge score was named as Inadequate Knowledge, 6-10 knowledge score named as moderate knowledge and 11-15 knowledge score named as adequate knowledge.

Method of Data Collection: The data was collected by using semi-structured interview technique. The duration of data collection period was 20 - 30 minutes per subject.

Statistical Analysis: The descriptive statistics like mean, percentage was used to assess the level of knowledge on diabetic diet among diabetic patients and Chi-square was used to find out the association between knowledge on diabetic diet among diabetic patients with selected demographic variables.

Study Finding: The collected study was tabulated and analyzed.. The study shows that 50% of sample had adequate knowledge. 24% of sample had moderate knowledge and 26% of sample had inadequate knowledge. There is a significant association between selected demographic variable such as sex, income, duration of disease and family history of diabetes mellitus with their knowledge. There is no significant association between age, education and dietary habits of diabetic patients with their knowledge.



Conclusion

According to the proverb prevention is better than cure, it is better to rectify abnormalities rather than to treat the complications. So that the Diabetic patient first make themselves physically fit with good dietary habits and Body Weight and serve the society around them.

Ethical Clearance: Obtained from Institutional Human Ethical Committee

Determine the Validity and Reliability of Structured Questionaire on Knowledge Regarding Care of Neonates among Peri Natal Mothers

Subbulakshmi S.[1], Sujatha Sridharan[2], Rajalakshmi[3]

[1]Research Scholar, Chettinad College of Nursing, [2]Professor, Department of Pediatrics, Chettinad Hospital and Research Institute, [3]Professor, Child Health Nursing, Chettinad Academy of Research and Education, Tamil Nadu, India

Abstract

A study to assess the validity and reliability of structured questionnaire regarding knowledge on care of neonates among perinatal mothers.. The objectives of the study were to assess the validity and reliability of structured questionnaire regarding care of neonates. A total of 50 peri natal mothers were participated in this study.The structured questionnaire was formulated. The total number of items in the questionnaire was 30. The reliability of the tool was assessed by Test-Retest split half and internal consistency reliability method . The validity of the questionnaire was measured by the face validity, content validity, construct validity and criterion validity method. The study results shows that in the test retest method the value for a Pearson's coefficient was r = 0.98, the spilit half techniques showed that r = 0.81. Cronbach's alpha value was r = 0.82, hence the questionnaire was highly reliable in assessing the level of knowledge on care of neonates among the perinatal mothers.

Keywords: *Validity, Reliability, care of neonates, Perinatal mothers.*

Introduction

In our world 140 million children are born every year. Where as 8 million infants die out of which 4 million infants die during the neonatal period, 98% of them do so in developing countries. Neonatal Mortality Rate is higher in rural area i.e. 49 per 1000 live birth and 27 per 1000 live birth in urban area[2].

According to a new UNICEF report (20.02.2018), the country's neonatal mortality rate at 25.4 deaths per 1,000 live births makes it 12th worst among 52 "lower middle-income countries" that pose risk for newborns. India is also the only major country in the world to have a higher mortality for girls than boys[4].

Neonatal mortality rate of India fell gradually from 49 deaths per 1000 live births in 1997 to 25.4 deaths per 1000 live births in 2018. Sanjay P Zodpey, conducted a study on Neonatal Morbidity and Mortality in Tribal and Rural Communities in Central India. Results showed that Pregnancy outcomes were available for 1,136 women, with an overall neonatal mortality of 73 per 1,000 live births[1]. The main causes of neonatal mortality were sepsis and respiratory illness. For tribal babies, mortality was also associated with maternal morbidity and delay in the initiation of breastfeeding. The knowledge on care of neonates among the mother is very essential in reducing the neonatal morbidity and mortality and to promote the optimal growth and development of neonates[3].

Topic of the Study: "A study to construct and to assess the validity and reliability of the questionnaire on knowledge regarding care of neonates among perinatal mothers in ante natal out patient department at selected tertiary care hospital, Kelambakkam, Kanchepuram District, Tamilnadu, India. ''

Objectives: To assess the validity and reliability of the structured questionnaire on knowledge regarding careof neonates among perinatal mothers.

Research Methodology

Research approach & research design: In this study the research approach was quantitative non-experimental evaluative approach and the research design was descriptive design.

Research Setting: The present study was conducted at ante natal out patientdepartment in Chettinad Hospital & Research Institute (CHRI), Kelambakkam, Kanchipuram District, Tamil Nadu.

Population: Perinatal mothers attendingantenatal out patient department in Chettinad Hospital & Research Institute (CHRI), Kelambakkam, Kanchipuram district, Tamil Nadu.

Sample technique & sample size: Non probability– Purposive sampling technique was used to select the perinatal mothers and the sample size was 50.

Inclusion Criteria: The study includes the peri natal mothers (mothers during 3rd trimester of pregnancy to 7th day of postpartum period), who are

- Able to read Tamil or English.
- Willing to participate in the study.

Exclusion Criteria:

The study excludes the perinatal mothers, who are

- Critically ill

Description of the tool: As the study aimed at evaluating the validity & reliability of the tool, A structured self-administered questionnaire containing 30 multiple choice questions with 4 possible options (total 120 items) were used to assess the knowledge on care of neonates. The researcher developed the tool by extensive review of literature.

The structured questionnaire consists of 6 aspects of neonatal care.

Which are:

- breast feeding
- thermo regulation measures for neonates
- infection control measures for neonates
- care of elimination of neonates
- Immunization for neonates
- danger signs of the neonates.

Tool Validity:

1. **Face validity:**

The questionaire is subjectively viewed for covering all the components of care of neonates by the experts and their suggestions and corrections were incorporated.

2. **Content validity:** The content validity of the tool was established in consultation with 10 experts i.e. 5 experts from Nursing & 5 experts from pediatric medical department and statistician. As per the suggestions of the experts the researcher has made the necessary modifications in the tool.

3. **Construct Validity:** The construct validity shows that the mothers who are already having children scored consistently higher than the primi mothers in the other group

The mothers who are already having children had an average score (mean±SD) of 18.2 ± 3.4 . The primi mothers had an average score (mean±SD) of 13.4 ± 4.3, hence the mothers who are already having children answered more questions correctly compared to the primi mothers.

4. **Criterian Validity:** In this study, Researcher has done a predictive validity on neonatal care based on the reviewed literatures. The reviewed literatures supported the criteria's presented in the tool.

Tool Reliability:

1. **Test-retest method:** Test-retest reliability involves administering the same measure to the same group of test-takers under the same conditions on two different occasions and correlating the scores. The reliability coefficient is simply the correlation (a Pearson's correlation) between the scores on the first and the second testing.

The value for a Pearson's coefficient was r = 0.98

2. **Split - half reliability:** The reliability of the tool was established by using splihalf method for assessment of the level of knowledge. The structured questionaire which has 30 items in it, was divided into odd and even items, to check its internal consistency. The co-rrelation co-efficient was calculated using the Spearman correlation coefficient formula.

The calculated value of r = 0.81. There by the tool was considered as highly reliable.

Internal consistency:

- The tendency towards consistency found in repeated measurements of the same phenomenon is referred to as reliability. Cronbach's alpha was used in assessing the reliability of tests for knowledge on neonatal care with questions that have four possible responses. Cronbach's alpha ranges from r=0 to 1, with r=0.7 or greater considered as sufficiently reliable.
- Cronbach's alpha value was r = 0.81. (questionairre)

Conclusion

The structured self-administered questionnaire (demographic proforma and knowledge questionnaire) evaluated in this study proved to be a valid and reliable to measure the knowledge on care of neonates. The questionnaire regarding care of neonates help to assess the level of knowledge on care of neonates which provides base for assessing the mother's knowledge and facilitates to organize health education sessions to the perinatal mothers in hospital and community setting. This must be addressed whenever they come for the ante natal review and the delivery of a baby. Further this will helps in creating awareness about care of neonates which in turn to promote the growth and development of neonates and help to reduce the neonatal morbidity and mortality.

Effectiveness of Aerobic Exercise on Short Term Memory and Sustained Attention among Developmental Coordination Disorder Children

Sujatha B.[1], Jagatheesan Alagesan[2], A. Brite Saghaya Rayna[3]

[1]Assistant Professor, [2]Professor, [3]BPT 4th Year, Saveetha College of Physiotherapy, Chennai, India

Abstract

The aim of the study is to determine the effects of aerobic exercise on the short-term memory & sustained attention among Developmental coordination disorder (DCD) children. The study is designed as single group experimental study. The study setting was done in school at Chennai according to the inclusion and exclusion criteria. Sampling technique used was Random sampling. The sample size was 20 subjects. The materials required were pulse oximeter, Bicycle ergometer, Weight machine, Stopwatch, Measuring tape, Stoop Test and Digit span Test. The result of the study from post-test value of Stroop test is 6.70 and pre-test is 11.30 there is slight decrease in the mean value this shows that stroop test due to aerobic exercise of high intensity interval training intervention slightly improved. P value is less than <0.001. The post-test value of digit span test is 0.460 and the pre-test is 0.537 from this there is slight difference in the statistical mean. P value is equal to 0.001. It has been concluded that the present study evaluated the impact of an aerobic exercise of high intensity interval training intervention on cognitive performance of short-term memory and sustained attention in school students. The result demonstrates the high intensity interval training improved the subjects short term memory and sustained attention by following the pre and post-test values of stroop test and digit span test.

Keywords: *Short-term memory, DCD, digit span test, stroop test.*

Introduction:

Developmental coordination disorder (DCD) is a mark of impairment in motor development which significantly interferes child's activities of daily living. Physical inactivity is due to wide spread sedentary lifestyle[1].

Children with developmental co-ordination disorder (DCD) face evident motor difficulties in activities of daily living (ADL).Assessment of their capacity in ADL is essential for diagnosis and intervention, in order to limit the daily consequences of the disorder. The aim of this study is to systematically review potential instruments for standardized and objective assessment of children's capacity in ADL, suited for children with DCD.As a rest step, databases of MEDLINE, EMBASE, CINAHL and PsycINFO were searched to identify studies that described instruments with potential for assessment of capacity in ADL, This life style change is associated with substantial increase in obesity, high blood pressure, high cholesterol, type2 diabetes & coronary heart disease throughout the life span during the childhood[2].

Regular physical activity has been shown to reduce the morbidity & motility associated with many of these chronic diseases. A large body of research shows that physical activity improves cognitive functioning[3].

Short term memory is the capacity for holding, but not manipulating, a small amount of information in mind in an active, readily available state for a short period of time. The duration of short-term memory seems to be between 15 to 30 seconds and capacity about 7 items[8]. Digit span test is a measuring tool for short term memory. Stroop test is a demonstration of interference in the reaction time of a task. when the name of a color (e.g. blue, green, red) is printed in a color which is denoted by the name (i.e. word red printed in blue ink instead of red ink)[9].

Hence the aim of the study is to evaluate the effect of aerobic exercise on short term memory in DCD children and to evaluate the effect of aerobic exercise on sustained attention in DCD children.

Methodology

The study is designed as single group experimental study. The study setting was done in school at Chennai according to the inclusion and exclusion criteria. Sampling technique used was Random sampling. The sample size was 20 subjects.

The inclusion criteria were DCD children were only included, both genders were taken between the age of 13 to 15 years who Did not have any musculoskeletal disorders. The exclusion criteria were BP greater than or equal to 150/90mm hg, Cerebral dysfunction, Cardiovascular problem and children with Allergies were excluded.

The materials required were pulse oximeter, Bicycle ergometer, Weight machine, Stopwatch, Measuringtape, Stoop Test and Digit span Test.

Procedure:

Data Collection Procedure: Atotal of 20 DCD children were diagnosed by DSM 5 criteria according to inclusion and exclusion criteria and the informed consent were obtained from all the subjects. The safety and simplicity about of the procedure explained. All the 30 subjects were selected using a random sampling technique. Subjects have been assigned into single group and high intensity interval training was given. Pre-test and post-test values of before and after exercise has been noted and considered as outcome values. The outcome measures are stroop test and digit span test. The data collected and tabulated was statistically analyzed.

Treatment procedure: Vitals (Blood Pressure, Heart Rate, pulse rate, respiratory rate) has been checked before starting the treatment procedure.

- Warm up phase. (10 minutes)
- Condition phase (20 minutes)
- Cool down phase (10 minutes)

The study was conducted as 3 sessions. In the 1st session the subject performed two pre-intervention working memory test: DIGIT SPAN TEST & "STROOP TEST" and values have been recorded and the 2nd session is a physical activity session in which the high intensity interval training has been given. and the last session is the post-intervention session immediately after the post intervention memory test and values has been recorded. This procedure has been given for the school students for 4 weeks, 3 days per week has been implemented and recorded.

High Intensity Interval Training:

Warm Up Phase: Stretching (3mins): Hamstring, quadriceps, gastrosoleus (each muscle for 15 secs, 3 repetition and rest period between each muscle is 15 secs).

Active range of motion (7minutes for both upper limb and lower limb).

Upper limb:

- Shoulder: flexion, extension, abduction, adduction, internal rotation and external rotation.
- Elbow: flexion and extension.
- Forearm: supination and pronation.
- Wrist: flexion, extension, ulnar deviation and radial deviation. Fingers: flexion, extension, abduction, adduction and opposition.

Lower limb:

- Hip: flexion, extension, abduction, adduction, internal rotation and external rotation.
- Knee: flexion and extension.
- Ankle: dorsi flexion, plantar flexion, inversion and eversion.
- Toes: flexion, extension, abduction and adduction.

Conditioning Phase: Subjects has been asked to peddle in bicycle ergo meter for 20 minutes (4*1 minute, 4min= peddling, 1min= recovering, gradually decreasing the intensity by 60 rotation per min) with the maintenance of % peak heart rate between 70 – 89 %. This % peak heart rate has been monitored by using the pulse oximeter.

Cool Down Phase: Stretching (3minutes): Hamstring, quadriceps, gastrosoleus (each muscle for 15 secs, 3 repetition and rest period between each muscle is 15 secs).Active range of motion (7minutes) for both upper limb and lower limb.

Upper Limb:

- Shoulder: flexion, extension, abduction, adduction, internal rotation and external rotation. Elbow: flexion and extension.
- Forearm: supination and pronation.
- Wrist: flexion, extension, ulnar deviation, radial deviation.
- Fingers: flexion, extension abduction, adduction and opposition.

Lower Limb:

- Hip: flexion, extension, abduction, adduction, internal rotation and external rotation.
- Knee: flexion and extension.
- Ankle: dorsi flexion, plantar flexion, inversion and eversion.
- Toes: flexion, extension, abduction and adduction.

Results

From the statistical analysis made with the quantitative data relieved a statistically slight difference between pre-test and post-test. The post-test value of stroop test is 6.70 and pre-test is 11.30 there is slight decrease in the mean value this shows that stroop test due to aerobic exercise of high intensity interval training intervention slightly improved. P value is less than <0.001.

The post-test value of digit span test is 0.460 and the pre-test is 0.537 from this there is slight difference in the statistical mean. P value is equal to 0.001.

Statistical analysis of both the stroop test and the digit span test revealed that there is a slight statistical difference seen in both the pre-test and post-test value.

Table 1: Pre-test and post-test Stroop Test

Group	Mean	Standard Deviation	T Value	P Value
Pre-Test	11.30	3.58	6.2279	>0.0001
Post-Test	6.70	3.49		

Table 2: Pre and post-test value. Digit Span Test

Group	Mean	Standarad Deviation	T Value	P Value
Pretest	0.537	0.192	4.4899	0.001
Posttest	0.460	0.157		

Discussion:

DCD is characterized by marked motor impairment that affects functioning in daily activities in the absence of intellectual or neurological dysfunction.[1]

Aerobic exercise is a physical exercise of low to high intensity that depends primarily on the aerobic energy generating process. Aerobic literally means "Relating to involving or requiring free oxygen" and refers to use of oxygen to adequately meet energy demand during exercise via aerobic metabolism generally high to moderate intensity activities that are sufficiently supported by aerobic metabolism can be performed for extended periods of time[11].

The aim of this study was to determine the "effectiveness of aerobic exercise on short term memory and sustained attention among DCD children". 20 subjects fulfilling the inclusion criteria were assigned to this study by randomization technique. Subjects were assigned into single group and high intensity interval training was given. Informed consent was taken from the subjects and the procedure was explained. single group (n=20) were receiving a high intensity interval training intervention over a period of 4 weeks,3 days/ week. Stroop test and digit span test were used as the tools for analysis the sustained attention and short-term memory. The outcome measure was taken before and after the intervention and after the end of 4th week.

Frank fincham etal,discussed that the purpose of this study was to evaluate the impact of a 4 week high intensity interval training intervention on cognitive performance in emerging adults. High intensity interval training shortly improved their mathematic and reading working memory scores from pre-test to post-test[12].

Cristiano R. R. Alves et al, discuss that the objective of this study was to assess the effect of an acute high intensity interval training session on selected parameters of cognitive functionlike (executive function and short-term memory performance) in middle aged groups. The main finding was that the high intensity interval training session improve the performance in the stroop "color word" test, which has been thought to be a measure of selective attention and the susceptibility to interference from conflicting stimuli. Conversely, the high intensity interval training slightly improves the performance in the digit span forward test has been considered as a measure of short-term memory[13]. Some authors have speculated that the exercise intensity affects the cognitive performance in u-shaped fashion, meaning that a high intensity exercise would improve cognition were as moderate intensity would impair the cognition.

Tomposiki et al, discussed that the study was to further investigate if exercise. In the form of interval training has an effect on memory function. It was hypothesized that exercise training that includes intermittent bouts of bicycling will have positive effect on memory retention. past studies have shown that acute continuous high intensity interval training improves cognitive function these past studies used the stroop test to measure cognitive function. The present study combined the success to investigate if moderate intensity interval training could also benefit cognitive performance using a list of 15 randomly generated words rather than a stroop test[14].

Working memory skills can explain individual differences in learning. Poor performance on working memory measures is characteristic of children failing to progress normally in the areas of reading [15].

It is worth noting that although those with DCD can have comorbid language impairments, their memory profile does not differ greatly compared to children with DCD and typical language skills [16].

The present study reveals the subjects who received the high intensity interval training shows that the slight improvement in the subject's short-term memory and sustained attention by concluding the pre-test and post-test result of stroop test and digit span test.

Conclusion

It has been concluded that the present study evaluated the impact of a aerobic exercise of high intensity interval training intervention on cognitive performance of short term memory and sustained attention in school students. The result demonstrates the high intensity interval training improved the subjects short term memory and sustained attention by following the pre and post-test values of stroop test and digit span test.

Effect of Moderate-intensity Aerobic Exercise in the form of Interactive Video Dance Gameon BMI and VO2 Max among Overweight Children between 9 to 14 Years

Sujatha B.[1], Jagatheesan Alagesan[2], A. Brite Saghaya Rayna[3]

[1]Assistant Professor, [2] Professor, [3]BPT 4th Year, Saveetha College of Physiotherapy, Thandalam, Chennai, India

Abstract

Background: Overweight reduces the VO2max in children hence they may have poor cardiovascular fitness, quality of life, lack of confidence and they are prone to develop cardiovascular diseases, diabetes mellitus, risk of fracture in future.

Objective: The objective of the study is effect of Interactive video dance game (IVDG) on Body mass index (BMI), maximum oxygen consumption (VO_2Max) and quality of life (QOL) in overweight children between age group of 9 to 14 years.

Method: The study is designed as an experimental study and the study setting is done Department of paediatrics, Saveetha medical hospital. sample size was 10 between the age 9 to 14 years and duration of the study was 8 weeks. Materials required for the study are Interactive Video Dance Game (IVDG), Short Form (SF) 36 questionnaire, stethoscope, pedometer and stop watch. BMI and VO_2Max of 20 samples were recorded as Pre-interventional score after a duration of 8 weeks again BMI and VO2max was recorded as post-interventional score.

Results: The pre-interventional score of mean and standard deviation of BMI were 24.2kg/m^2 ± 0.52. The mean and standard deviation of VO_2Max were 16.45ml/kg/min ± 2.05 the mean and Standard deviation of the score of SF 36 questionnaire was 47.3 ± 1.72 it shows a poor quality of life and reduced physical activities. the post-interventional score of BMI were 22.64 ± 1.02, VO_2Max were 21.97ml/kg/min ± 0.56, the Sf 36 questionnaire score were 56 .7 ± 0.63 shows an improved quality of life and physical activities.

Conclusion: Interactive video dance game is an effective and enjoyable exercise program for overweight children who wish to decrease their BMI and improve components of cardiorespiratory fitness.

Keywords: *Interactive video dance game, moderate-intensity, BMI, VO2 Max, overweight.*

Introduction

According to the new guidelines for Asians "BMI between 23 to 24.9kg/m^2 is considered to be overweight[1]. Overweight children may have a risk of developing obesity in future and this may causes dangerous complications such as, cardiovascular diseases like risk of both fatal and non-fatal myocardial infarction, Increased presence of atherosclerosis in both aorta and coronary artery and Hypertension[2], metabolic disorders such as Insulin resistance results in Type 2 Diabetes mellitus, Increased level of insulin in circulation and Dyslipidaemia[3], orthopaedic complications such as Greater risk of fracture when compared to underweight, Greater impaired mobility, Knee pain and Malalignment in both metaphyseal- diaphyseal and anatomic tibiofemoral angle[4]. Gastrointestinal system diseases such as Non-alcoholic fatty liver which is Seen in40 to 50% in children[5], psychosocial problems such as Depression, Abnormal eating and exercise pattern and Lower health-related quality of life[6], pulmonary complications such as sleep apnoea[7].

Overweight and obese children will have very high

lipoprotein which reduces the VO2max and this signifies the children have poor cardiorespiratory fitness, this may directly or indirectly cause the above-mentioned complications.

One of the main causes of obesity in present generation is lack of physical activities due to over usage of playing in smart phones, watching TV and video games. Many studies have been conducted with IVDG and it has been effectively increasing the physical activities[8,9,10]. It has been proven that energy expenditure is higher in IVDG when compare to sedentary video playing and walking[8].

aerobic exercise helps to improve the cardiorespiratory fitness. In our study we have preferred moderate-intensity aerobic exercise because high-intensity exercise in obese children may leads to musculoskeletal injuries whereas moderate-intensity effectively increases the VO_2Max and prevents skeletal muscle injuries.

Prescribing exercise for the overweight children may fail to follow the protocol and it may again worsen the condition hence interactive video dance game makes the physical activity enjoyable and interesting and hence the aim of the study is to reduce the BMI by using video game, to make exercise into an interesting activity and to improve VO_2max in overweight children and to improve physical activity and quality of life

Methodology

The study is designed as an experimental study and the study setting is done Department of paediatrics, saveetha medical hospital, thandalam, Chennai-602105, sample size was 2 between the age 9 to 14 years and duration of the study was 8 weeks.

Materials required for the study are Interactive Video Dance Game (IVDG) which is available in online stores and it is cheap, Short Form (SF) 36 questionnaire to determine the quality of life, stethoscope to measure heart rate, pedometer to monitor intensity of exercise and stop watch for monitoring duration of exercise.

The inclusion criteria for the study are Children within BMI of 23 to 24kg/m^2, Children between the age of 9 to 14years and Children with lack of physical activity. The exclusion criteria are Children with structural and functional abnormality of heart, Children who are already in weight loss program, Children with physical and mental disability, Children with endocrine pathology, Children with visual defect and Children with auditory defect.

Saveetha medical hospital has conducted a camp in which 67 apparently normal children's age, height and weight was recorded in which 20 children based on inclusion and exclusion criteria were selected for the study, their VO_2Max were recorded by measuring the resting heart rate and maximum heart rate by using 3-minute step test and SF 36 questionnaire were given and the score is recorded as pre-interventional score. The children undergo 5 minutes of Warm-up exercise followed by 20 minute of moderate-intensity aerobic exercise in the form of IVDG and 5 minutes of Cool-down exercise were given for 3 days per week. The protocol is followed for 8 weeks after that VO2max is again calculated and Sf 36 score were again measured and recorded as Post-interventional score respectively.

Results

The pre-interventional score of mean and standard deviation of BMI were 24.2kg/m^2 ± 0.52. The mean and standard deviation of VO_2Max were 16.45ml/kg/min ± 2.05 the mean and Standard deviation of the score of SF 36 questionnaire was 47.3 ± 1.72 it shows a poor quality of life and reduced physical activities as shown in Table No. 1. the post-interventional score of BMI were 22.64 ± 1.02, VO_2Max were 21.97ml/kg/min ± 0.56, the Sf 36 questionnaire score were 56 .7 ± 0.63 shows an improved quality of life and physical activities as shown in Table.no.2. The total decrease in BMI was 1.56kg/m^2 and increase in VO2Max was 5.52% ml/kg/min respectively as shown in Figure.no.1.

Table No. 1: Pre- interventional score

Components	Mean	Standard Deviation
BMI (kg/m^2)	24.2	0.52
VO2max (ml/kg/min)	16.45	2.05
SF- 36	47.3	1.72

Table No. 2: Post- interventional score

Components	Mean	Standard Deviation
BMI (kg/m^2)	22.64	1.02
Vo2 max (ml/kg/min)	21.97	0.56
SF-36	56.7	0.63

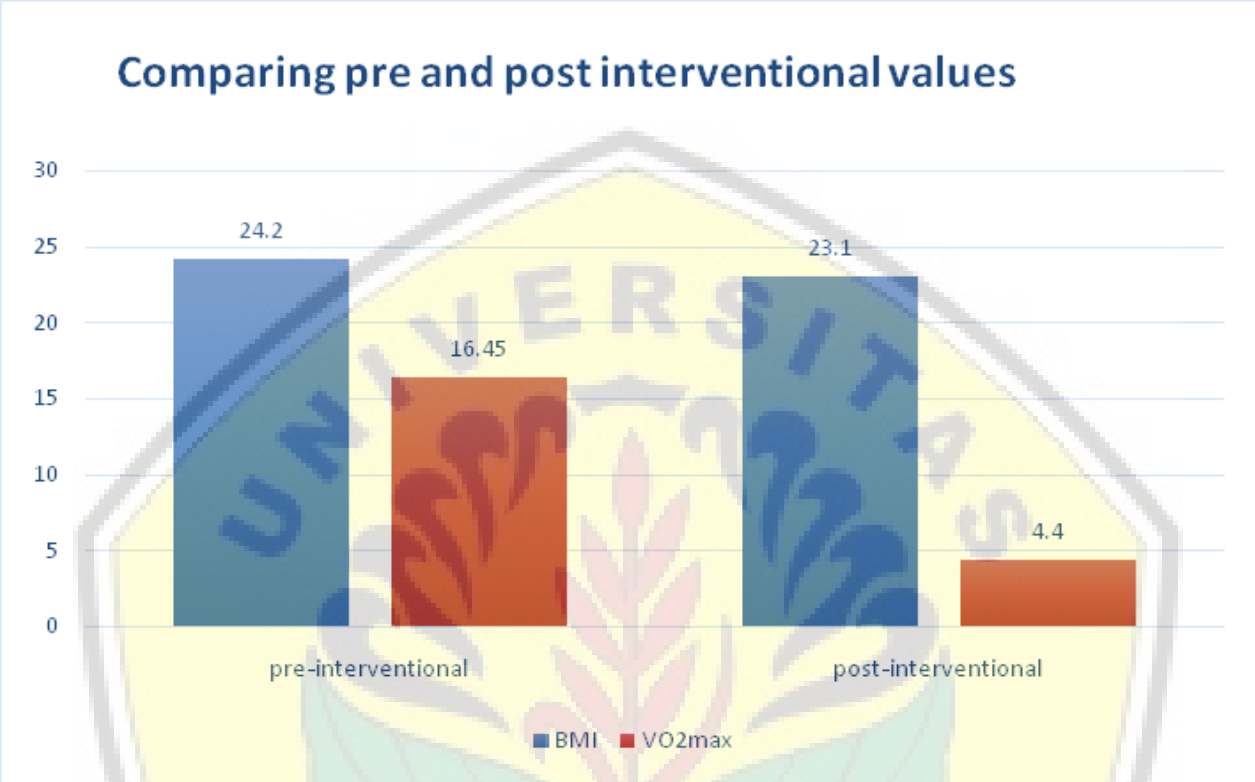

Figure No. 1

Discussion

The prevalence rate of obesity has been reached 1 billion overweight out of 300 million children[2]. School aged children are affected more[11]. The main causes for overweight are economic development, genetic factor, increased energy intake and lack of energy expenditure among the children[2,12]. Our study has decreased the BMI and improves VO_2Max through IVDG and moderate-intensity aerobic exercisewhich also improved their quality of life.

Mejia-Downs et al.,., has done a study by using IVDG among children with duration of 6 weeks and have reduced BMI of 0.75kg/m^2 and improved VO_2Max of 1.03ml/kg/min respectively[13] but in our study within the duration of 8 weeks BMI of 1.56kg/m^2 has been reduced in children and there is an significant improvement in VO_2Max 5.52% ml/kg/min, it may be due to the effect of Moderate-intensity aerobic exercise respectively.

Graciaet al.,have done a study by using high intensity interval training for a duration of 8 weeks and he determined that there are no changes in the BMI but there was an increase in VO_2Max 1.92ml/kg/min[14]but in our study there is a decrease in BMI and a significant increase of VO_2Max among children, hence our study is really an effective intervention.

Mogharnasiet al., have studied aerobic based training to reduce the BMI in a duration of 4 weeks and he determined that the BMI has been decreased 0.94kg/m^2 and VO_2Max has been increased 6.76%[15], their study has a significant decrease in BMI but it slightly increases the VO2Max but in our study the intervention was effect for both BMI and VO_2Max

Maffeiset al., have studied effects of cycling on

BMI and VO_2Max and he determined that BMI has decreased 0.62kg/m^2 and increases 6.02% of VO_2Max within the duration of 6 weeks respectively[16] but there is a significant decrease in BMI and increased VO2Max in our study when compared to their study.

Hence there was a drastically decrease in BMI and increase in VO2Max in our study when compared to other studies and hence the protocol designed by us was effective and it is enjoyable.

Conclusion

Interactive video dance game is an effective and enjoyable exercise program for overweight children who wish to decrease their BMI and improve components of cardiorespiratory fitness. Moderate- intensity aerobic exercise helps in cardiorespiratory fitness.

Sociocultural Correlates of Infant Mortality among the Rural Tribes in Meghalaya

Sunny Joseph Mavelil[1], S.C. Srivastava[2]

[1]Ph.D. Scholar, [2]Professor, Department of Rural Development and Agricultural Production, North-Eastern Hill University, Chasingre, P.O. Chandmari, Tura, West Garo Hills District, Meghalaya, India

Abstract

Background: The infant mortality is comparatively high among the rural tribes in India. This study examines the sociocultural factors that are correlated with infant mortality among the rural tribes in Meghalaya.

Method: Data from 900 tribal women lived in 142 villages which were randomly selected from 15 PHCs across five districts in Meghalaya. A semi-structured validated questionnaire consisting of socio-demographic details of the respondents, social profile of the deceased and sociocultural variables pertaining to the infant mortality rate (IMR).

Results: Respondents' median age was 28.9 years, 83% had primary education and 82% got married in the age group of 13–18 years. Over 96% of the respondents lived with their spouse and 80% had a monthly income ≤ Rs.5000. About 10.3% of respondents had three deliveries within a four-year period. Out of the deceased between the years 2014 and 2017, the infant mortality was 69% among the rural tribes. About 33.3% did not avail medical service from PHCs. Significant correlations were found between IMR and marital status (p=0.000), age of mother (p=0.003), frequency of antenatal check-ups (p=0.005), the immunization status of children (p=0.015) and family size (p=0.018).Mother's educational qualification, occupation and economic status were uncorrelated.

Conclusion: Infant mortality was correlated with maternal, prenatal, perinatal and neonatal determinants among tribes in rural Meghalaya. Findings support the need to focus on the age of the mother, marital status, family size and prenatal, perinatal and neonatal care.

Keywords: *Infant mortality, sociocultural, correlates, rural, tribe.*

Introduction

Infant and child mortality rates of a nation most often reflect its social and economic development. To this regard, India has made notable attempts in reducing both infant mortality and under-five mortality rates and a few states (namely Kerala, Tamil Nadu, West Bengal, Maharashtra, Punjab and HimachalPradesh) have almost achieved the Millennium Development Goal (MDG) by 2015[1 – 4]. However, as a nation India is yet to realize the same. It is evident that there are disparities related to socioeconomic condition, educational background, maternal health and child welfare, health facilities and environmental factors across different states and various social and/or ethnic groups in India. Besides, infant mortality has been higher among the scheduled tribe families in comparison to the generalpopulation[5]. Studies carried out in India and other nations found that infant and child mortality were associated with the sex of the child, mother's religion and ethnicity, income of

Corresponding Author:

the household, birth order, mother's age at marriage and childbirth, birth intervals, availability of professional antenatal and delivery care, full immunization of children, mother's education, urban-rural residence and mother's exposure to mass media[6-11].

One of the studies that found the decline in the infant mortality rate over a decade provided a framework foranalysing contributing factors[12]. These included: a) proximate factorssuch as nonmedical factors and medical care during the antenatal period,care at birth and preventive and curative care in the postnatal period); b) maternal factors like age, parity, andbirth intervals; and c) household and community-level factors such as water, sanitation and housing. This study has made a case for increased access to a minimum package of essential services in order to reduce the infant mortality rate. A few other studies also laid out intervention strategies and directions based on similar assumptions [13–17]. However, there was a gap in analysing the socio-economic and cultural factors correlated with the reduction of infant and child mortality rates in India.

As mentioned in the Mosley Chen Framework[18] the determinants of infant and childmortality are divided into three categories (i)biological factors; (ii)socio-economic factors; and (iii)environmental factors. In India, related to the socio-economic factors, a number of studies have shown that an infant born in a scheduled tribe has 19 per cent higher risk ofdying in the neonatal period and 45 per cent risk of dying in the post-neonatal period in comparison to other social classes. Besides, there is a disproportionate increase inchild mortality (aged 1-4 years) in scheduled tribes compared with the non-scheduled tribes[19-20]. Further, infant mortality is high among the scheduled tribes in rural areas compared to urban areas [20-21]. Overall, there is an increased possibility of deaths of infants in rural as compared to urban areas and the risk is exacerbated among scheduled tribes in India [22-23]. However, there is a dearth of studies carried out to understand the sociocultural correlates of infant mortality rate in India and to our knowledge this is the first of its kind study carried out in the state of Meghalaya.

Materials and Method

The present quantitative study was carried out in the Garo Hills Division of Meghalaya in 2017. There were five districts in the Garo Hills Division and the National Rural Health Mission (NRHM) provided health services through the Primary Health Centres (PHCs) and Community Health Centres (CHCs). People across the tribes in those districts started availing services from PHCs. A total of 37 PHCs were functional across five districts in the Garo Hills Division in 2017. For the purpose of the present study, we randomly selected 15 PHCs from a total of 37 PHCs and the random selection was done by the then government officials of the respective district. The then medical officers or their representatives, if the medical officer was unavailable, randomly sampled 142 villages mapped to the 15 PHCs. Senior staff from each PHC randomly selected five respondents each from 142 villages. Thus, the sample of the study consisted of a total of 900 respondents including 760 respondents randomly sampled from 142 villages and 140 Accredited Social Health Activists (ASHAs) worked in those sampled 142 villages. The principal and co-investigators met the Medical Officers in charge of the 15 PHCs and the meetings with ASHAs were ascertained. We obtained the Ethical Committee clearance to conduct the study.

Post to the receipt of the Ethical Committee's approval, the principal investigator trained the three co-investigators and an Auxiliary Nurse Midwifery (ANM) in the research protocol and the survey tool. The research team met the study participants and explained them about the objectives of the study. The research team ascertained the voluntary participation in this study and informed verbal consent was obtained from each respondent who volunteered to respond to the survey questionnaire. No personal identifiers were mentioned in the survey tool in order to maintain confidentiality.

The survey tool was first written in English and then got translated into the Garo language as it is widely spoken in the Garo Hills Division of Meghalaya. Later the tool was pilot tested on 60 subjects and we made a few changes in the questionnaire based on the answer options given by the pilot study respondents. Following the modification, we back-translated the questionnaire into English and tested again it on 60 respondents to check the reliability of the back-translated questionnaire and the Cronbach's alpha of the revised version of the survey tool was 0.89.The finalized version of the semi-structured interview schedule had a detailed proforma to recordsocio-demographic details, the dependent variables of infant and child mortality rates and the independent variables of sociocultural factors.

First, we entered the collected data into Microsoft

Excel and then we exported to IBM SPSS (version 20.0). We coded, recoded and analysed the data using SPSS version 20.0. We applied statistical method including descriptive statistics, inferential analysis to find correlations between variables and used Chi-square tests to find the statistically significant sociocultural correlates of infant and child mortality rates.

Findings: There were 900 women respondents from the randomly selected 142 villages spread across the five districts. The proportion of sample selected from each district is as follows: 13.3% from the East Garo Hills, 20.7% from the West Garo Hills, 12.7% from the South Garo Hills, 26.7% from the South West Garo Hills and 26.7% from the North Garo Hills of Meghalaya where all the NRHM program was implemented.

Table 1. Socioeconomic details of the respondents

	Women (N=900)	
Variable	**n**	**%**
Age of respondents		
17-25	353	39.2
26-35	376	41.8
36 & above	171	19.0
Education level		
Illiterate	156	17.3
Primary School	330	36.7
High School	357	39.7
Higher Secondary School	47	5.2
Graduation	10	1.1
Occupation		
Farming	582	64.7
Monthly salary earner	94	10.4
Daily wage earner	224	24.9
Monthly income		
Rs. 5000 or below	765	85.0
Rs. 5000- 7000	48	5.4
Above Rs.7000	87	9.6
Marital status		
Married & with husband	867	96.3
Widowed	33	3.7

The median age of the respondents was 28.9 years and about 96% of the respondents were married and had lived with their spouse at the time of the study. Almost 83% of them had a minimum primary education as their educational qualification. About 65% of them engaged in farming activities to earn their livelihood and 80% of the respondents had a monthly income of INR. 5000/or below. Out of the 900 study participants, 81.7% of them got married when they were in the age group of 13 – 18 years. While 87% of them chose their own life partner, 12% of the respondents had their marriage arranged by their family members. Before 18 years of age, almost 77% of the respondents had their first pregnancy. Between a four-year period from 2014 to 2017, over 10% of the respondents had three deliveries.

Table 2. Frequency and social profile of the deceased between 2014 and 2017

	Women (N=900)	
Variable	**n**	**%**
Death occurred in the family between 2014-2017		
Yes	81	9.0
No	819	91.0
Age group of the deceased (n=81)		
< 1 year	56	69.1
1-5 years	5	6.2
> 5 years	20	24.7
Sex of the deceased (n=81)		
Male	44	54.3
Female	37	45.7
Cause of death (n=81)		
Peri, neo and postnatal complications	34	42.0
Communicable diseases	2	2.5
Non-communicable diseases	45	55.5
Health services availed from PHC (n=81)		
Yes	54	66.7
No	27	33.3

In our study, 81 (9.0%) respondents reported at least one death in the family between 2014 and 2017. Out of the total 81 reported deaths, there were 44 male and 37 female family members. When the death occurred, 56 (69%) out of 81 were below the age of one (infant mortality) and five of them died when they were between the age of 1 – 5 years (child mortality). Out of the 56 deceased infants, 34 of them died due to perinatal, neonatal and postnatal complications. When the family member was ill before death, about 27 (33.3%) deceased were not taken for allopathic treatment.

Table 3. Sociocultural correlates of IMR

	Women (N=900)		
	IMR (n=56)		
Variable	**Yes (# & %)**	**No (# & %)**	**p-value**
Age of respondents			
17 to 20	10 (9.1)	100 (90.9)	0.003
21 to 25	24 (9.9)	219 (90.1)	
26 to 30	12 (4.7)	242 (95.3)	
>30	10 (3.4)	283 (96.6)	
Educational qualification			
Illiterate	7 (4.5)	149 (95.5)	0.625
Primary	25 (7.6)	305 (92.4)	
Above high school	24 (5.8)	390 (94.2)	
Age at marriage			
< 18	13 (12.1)	94 (87.9)	0.687
about 18 years	35 (5.7)	584 (94.3)	
about 21 years	8 (4.8)	166 (95.2)	
Marital status			
Married	44 (5.2)	797 (94.8)	0.000
Remarried	12 (20.3)	47 (79.7)	
Family size			
1 to 3	19 (9.0)	191 (91.0)	0.018
4 & 5	27 (6.4)	396 (93.6)	
6 & above	10 (3.7)	257 (96.3)	
No. of antenatal check-ups			
One	1 (3.7)	26 (96.3)	0.005
Two	3 (5.4)	53 (94.6)	
Three	11 (7.0)	147 (93.0)	
Four	40 (7.1)	526 (92.9)	
No antenatal check-ups	1 (1.1)	92 (98.9)	
Immunization status			
All children received	46 (6.3)	680 (93.7)	0.015
Some children received	4 (3.9)	98 (96.1)	
No children received	6 (8.3)	66 (91.7)	
Occupation			
Farming	31 (5.3)	551 (94.7)	0.230
Daily wage earner	21 (9.4)	203 (90.6)	
Monthly salary earner	4 (4.3)	90 (95.7)	
Monthly income			
< Rs.5000	47 (6.2)	716 (93.8)	0.438
> Rs.5000	9 (6.6)	128 (93.4)	

As evident in Table 3, there were statistically significant correlations between IMR and sociocultural variables such asthe age of the respondents, marital status, family size, number of antenatal check-ups and immunization status. In our study, variables such as educational qualification of mother, age at marriage, occupation and economic status did not have statistically significant correlation with the IMR. The Ch-square tests found the variable of marital status having the highest level of statistically significant correlation with IMR (p=0.000) followed by age of respondents (p=0.003), number of antenatal check-ups (p=0.005), the immunization status of children (p=0.015) and family size (p=0.018). Thus it is inferred that mother's educational qualification, her age at marriage, her occupation and income were not the correlates but marital status of the mother in the tribal village, family size, her age, the number of antenatal check-ups she had and the immunization status of her children were the significant correlates of IMR among the tribes in rural Meghalaya.

Conclusion

In conclusion, analysis of infant mortality in a four-year period showed a very slow decline among tribes in rural Meghalaya. For decreasing the IMR, the ongoing programmes of National Health Mission (NHM) aim at sensitizing women on sexual and reproductive health services, perinatal care, supplementary foods, breastfeeding practices and immunization. In addition to these, our study findings make a case for educating the tribal people on the sociocultural correlates such as increasing age at marriage, living with a spouse in the marital relationship, optimal family size, age at first birth, increasing the birth interval between two births and addressing gender-based discrimination among tribes.

Effect of pre-operative video teaching on anxiety among patients undergoing endoscopic urological surgeries

Surekha Vilas Sabale[1], Rupali Salvi[2], Sucheta Yangad[3], Nisha Naik[3]

[1]M.Sc. Nursing, [2]Principal, [3]Associate Professor, Dr. D.Y. Patil University, Pimpri, Pune

Abstract

Introduction: Anxiety is a normal adaptive response among surgical patients. It is anticipated to occur due to the stress of surgery and can occur at any time throughout the perioperative period.

Potential sources of anxiety include anticipation of impending surgery, Pain and discomfort, changes in body image or function, role changes, loss of control, family concerns, or potential alterations in lifestyle. Preoperative video teaching about the procedure may help reduce anxiety among the patients.

Objective: The objective of this study was to assess effect of video teaching on anxiety levels among patients undergoing endoscopic urological surgery.

Materials and Method: Pre-experimental one group pre-test post-test design was used for the study. To assess the anxiety levels among patients undergoing endoscopic urological surgery. Nonprobability purposive sampling technique was used to select 60 samples from selected hospitals. Demographic details were collected with semi structured questionnaire, anxiety was assessed using Hamilton Anxiety Scale and structured video teaching was provided after pretest.

Results: The analysis was done by using descriptive and inferential statistics. Researcher applied paired t test for pre and posttest anxiety score assessment and Fisher's exact test for analysis of association of anxiety scores with demographic variables of the patients.

Conclusion: Anxiety if not addressed before surgery may cause varied levels of physiological responses which may interfere with postoperative recovery. Therefore it is good to plan a virtual education before planned surgery to eliminate adverse effects of unaddressed anxiety.

Keywords: *Effect, video teaching, anxiety, endoscopic surgery.*

Introduction

Since human beings first learned to perform surgeries, they have used their creativity and intelligence to develop surgical techniques. Each time more advanced than the previous. Today surgery has evolved into a medical art and science with various revolutions like minimal invasive surgeries, endoscopic and robotic surgeries. With recent advances in surgical techniques problems of bleeding, pain, scar, wound infections, as well as associated morbidity and mortality of open surgeries have been reduced significantly.

A study done on patients with coronary artery bypass surgery revealed that patients previous experience with any surgery along with other causative factors of anxiety are responsible for various physiological responses. Severity of anxiety may vary depending upon previous positive or negative impact of hospitalization. Factors

like being in an unfamiliar environment, inability to decide care for oneself, fear of long-term effects of surgery, fear of complications, might increases anxiety.[1]

Comparative study of 200 patients undergoing cataract surgery revealed reduction in anxiety scores of patients undergoing cataract surgery in experimental group. Whereas, highest anxiety scores among control group were calculated. The Amsterdam Preoperative Anxiety and Information Score (APAIS) was used in this study.[2]

Dedicated healthcare staff for preoperative teachings to indoor patients may help reduce anxiety of hospitalization through patient and family education. Addressing their concerns and clearing their doubts about surgery. If patients and family members are allowed to verbalize their doubts physiological manifestations of anxiety may reduce and help in postoperative recovery and good postoperative results.

As anxiety may lead to increased protein breakdown, decreased wound healing, altered immune response and increased risk of infection and fluid and electrolyte imbalance. Pre-operative teaching about the procedure is proved to be an excellent tool for the positive impact on anxiety levels of any patient undergoing any procedure in the hospital environment.

A person undergoing operative intervention identifies anxiety as an unpleasant feeling, a state of apprehension, which may be observed as abnormal hemodynamics. Due to resultant autonomic nervous system stimulation, leading to fight or flight response. It begins as soon as the surgical procedure is planned and increases to maximal intensity at the moment of entering the hospital for surgery.

Preoperative period is the time when most patients experience significant fear regarding surgery and its outcome. They usually enter the clinic with fear of unknown. This study has demonstrated pathophysiological responses of preoperative anxiety. This anxious state tends to prevail through postoperative period. Researchers of this study recommended preparing patients (informing) about what to expect during the surgical experience, so that pathological effects of anxiety are reduced; as the patient feels more in control of his situations.[3]

Anxiety, fear and pain is never ending cycle. Especially when you are undergoing through an unknown or unexpected situation in life like; surgery, managing anxiety becomes the topmost priority to manage the situation with minimum distress.

A pre-experimental study was conducted by Samida Das from Bhubaneshwar, with purpose to assess the effect of pre-operative video assisted teaching (VAT) on knowledge and anxiety among the patient undergoing abdominal surgery. The study was done with one group pre-test post-test design total samples were (n=60). A self-structured questionnaire was developed to assess the knowledge (r = 0.72) and standardized Hospital Anxiety Depression Scale tool used to assess the anxiety. The pre-test was conducted, then VAT was provided, followed by post-test on 8th day. There was great increase in knowledge score (mean difference=8.12) and decrease in anxiety (mean difference=9.79) and a negative correlation between knowledge and anxiety. A chi square association was performed with knowledge showing significant relationship with age, sex, previous hospitalization, previous abdominal surgery, duration of hospitalization, types of abdominal surgery and socioeconomic status, but with anxiety showing significant relationship only with socioeconomic status (p=0.005). These results suggest that pre-operative education is effective and should be incorporated into routine practice in reducing anxiety and improving knowledge among patients.[4]

Research studies done worldwide evaluate the effect of anxiety on patients undergoing operative procedures even when the procedures are planned-ones; concluded that they create a lot of disturbance into one's emotional balance. Well informed or a virtual understanding of the fact may help in reducing fear and anxiety among patients.

As video teaching is a personalized intervention it may help them to express their concerns from known to the unknown.

As the researcher has more than 30 years of experience in the operation theatre and recovery units of multispecialty hospitals and seen many patients suffering with procedure related anxiety she has decided to work on the anxiety reduction of patients undergoing endoscopic urological surgeries.

A study done in China on patients undergoing cardiac surgery where the participants received preoperative education experienced a greater decrease in anxiety score (mean difference -3.6 points, 95%

confidence interval -4.62 to -2.57; P<0.001) and a greater decrease in depression score (mean difference education group reported less interference from pain in sleeping. The study confirms preoperative education -2.1 points, 95% CI -3.19 to -0.92; P<0.001) compared with those who did not. There was no difference between groups in average pain, current pain and interference in general activity, mood and walking ability. Researchers recommended that based upon existing evidence and international practice, preoperative education should be incorporated into routine practice to prepare cardiac patients for surgery.[5]

systematic review was conducted to investigate the effectiveness of various preoperative educational interventions in reducing preoperative anxiety. Fourteen interventional trials (12 randomized controlled trials and two pre/posttest trials) involving a total of 1752 participants were included in the review. Eight of the fourteen trials demonstrated that preoperative education intervention reduced preoperative anxiety significantly (P<0.05). It can be concluded that preoperative education interventions are promising in reducing preoperative anxiety in patients scheduled for surgical procedures.[6]

Material and Method

Study Objectives:

1. To assess the level of anxiety among patients before administration of video teaching.
2. To determine the effect of video teaching on the anxiety scores of patients undergoing endoscopic urological surgery.
3. To find the association of anxiety with selected demographic variables

Study Design: Study is based on Pre-experimental one group pre-test post-test category of quantitative experimental research, has some manipulation of independent variable in terms of the post video assisted teaching. Questions related to their surgery addressed in the video. Study has limited control over extraneous variables in terms of previous exposure to surgery or hospital environment. Assessment of anxiety status was done with help of Hamilton's anxiety assessment scale (HAM-A), a standardized anxiety rating scale.

Findings:

Section II:

Table 1: Effect of pre-operative video teaching onanxiety among patients undergoing endoscopic urological surgeries N=60

Anxiety	Pretest		Posttest	
	Freq	%	Freq	%
Mild (Score 1-3)	2	3.3%	30	50.0%
Moderate (Score 4-6)	13	21.7%	27	45.0%
Severe (Score 7-10)	45	75.0%	3	5.0%

Table 2: Paired t-test for the effect of pre-operative video teaching onanxiety among patients undergoing endoscopic urological surgeries N=60

	Mean	SD	T	df	p-value
Pretest	11.2	5.4	10.9	59	0.000
Posttest	3.7	2.7			

Researcher applied paired t-test for the effect of pre-operative video teaching on anxiety among patients undergoing endoscopic urological surgeries. Average anxiety score in pretest was 11.2 which reduced to 3.7 in posttest. T-value for this test was 10.9 with 59 degrees of freedom. Corresponding p-value was small (less than 0.05), the null hypothesis is rejected. This is evident that the anxiety of the patients undergoing endoscopic urological surgeries reduced significantly after pre-operative video teaching.

Section III: Analysis of data related to the association of anxiety with demographic variables

Table 3: Fisher's exact test for association of anxiety with demographic variables N=60

Demographic Variable		Mild	Moderate	Severe	p-value
Age in years	21-30	0	4	9	0.363
	41-50	1	1	16	
	51-60	1	5	9	
	61-70	0	3	10	
	71-80	0	0	1	
Gender	Male	0	4	19	0.503
	Female	2	9	26	
Education	Illiterate	0	1	9	0.087
	Primary	1	9	16	
	Secondary	0	1	13	
	Higher Secondary	0	2	2	
	Graduate	1	0	5	
Duration of surgery	Less than 2 hours	2	13	34	0.097
	2-4 hours	0	0	11	
Associated medical illness	Yes	1	9	30	1.000
	No	1	4	15	
Previous experience of surgery	Yes	1	10	30	0.658
	No	1	3	15	

Since p-values corresponding to all the demographic variables are large (greater than 0.05), none of the demographic variables was found to have significant association with the anxiety of the patients undergoing endoscopic urological surgeries.

Discussion

Study findings revealed reduced posttest anxiety scores among all cases undergoing endoscopic urological surgery. As more than 75% cases had recorded severe anxiety during pretest had reported reduction in anxiety score during posttest. Only 5% cases were recorded with severe anxiety scores during posttest.

Results of paired t-test for the effect of pre-operative video teaching on anxiety among patients undergoing endoscopic urological surgeries revealed that; Corresponding p-value for the pretest and posttest scores calculated was small (less than 0.05), therefore null hypothesis; There is no effect of video teaching on anxiety among patients undergoing endoscopic urological surgery was rejected.

Conclusion

It is evident from the research conducted that video teaching is a cost-effective method of reducing preoperative anxiety among patients undergoing endoscopic urological surgery. It is recommended for patients with or without previous experience of surgery as every experience is unique to the individual and psychological makeup varies with every experience.

SAQ Training Effect on Coordinative Abilities of University Level Male Cricket Players

Surinder Kumar

Asst. Prof. Department of Physical Education, Lovely Professional University, Phagwara

Abstract

Objective: The objective of this study was to check the Speed Agility Quickness (SAQ) training effect on Coordinative Abilities on University level cricket players.

Method: A total no. of twenty (20) samples of boys of University level players of department of physical education from Lovely Professional University, were randomly selected for the study. The pre-test and post-test was taken for find out the appropriate outcome. To find out the effect of the SAQ training on coordinative abilities, some drills of Speed Agility and Quickness has applied on the group of experimental in comparison of control group.

Result: According to the present study, there is a significant effect of SAQ drills on coordinative abilities of University level cricket players.

Keywords: *Speed Agility Quickness (SAQ), Cricket, Coordinative Abilities*

Introduction

Speed Agility Quickness (SAQ) Programme: It is a programme to help athlete to reach their optimum level, the athlete enhance their performance level due to help of this programme in every sport. Speed, agility and quickness is useful in every sports. If any person learn and master the skills of SAQ, he can take his performance to next level (Sahan[1]; Jovanovic et al[2].). It an athlete has the training programme regular and systematic than he can develop his skills and also can develop a fine atmosphere. Training will focus on the developing explosive movements, sports specific skills, love strength and techniques (Zoran[3]).

Coordinative Abilities: An ability to perform quickly and purposefully in the different or difficult comprehensive movement structure. In his context, coordinative abilities as understood as an extremely visible manifestation (a clear appearance) of controlled and regulated process of a motor activity of the central nervous system (Rosin[4]). Coordination ability is used for maximal utilization of technical skill, tactical skill and coordinative ability. An ability to achieve a superior level of harmony of an individual in physically movements and phase turning. In this we can able to change the position (development) and movement of physical movement and space in relative of related field of action. It is much helpful to coordinate the body parts and combination of limbs. It is helpful to improve the ability for quick action a signal.

Objective of Study: To know the effect of SAQ drills on coordinative abilities.

Definition and Explanation of the Terms:

Quickness: Ability of as person/athlete to execute movement skill in comparatively brief amount of time is part of the athleticism continuum (time) [2]

Reaction Time: Time lapsed (time pass by) between the athlete's recognizing the used to art and initiating the appropriate action.

Total Reaction Time: To execute the reactionary movement is of concern in summation of reaction time and time it takes. These are: Proper movement skills, Speed of movement

Hypothesis: Study is highlighting a particular set of

coordinative abilities that can be improve through SAQ training.

Procedure and Method

Sampling- A total no. of twenty (20) samples of boys of University level players of department of physical education from Lovely Professional University, were randomly selected for the study. Further There is division of two groups, one is experimental (N=10) and the other is control group (N=10).

Method: The training is designed for checking the effect of SAQ on coordinative abilities. The SAQ are followed for 5 days a week. Training was given to the players for 6 week.[2] Different coordinative variable was selected i.e. Balance, Coupling, Orientation, Rhythm, Reaction. The pre-test and post-test was taken for find out the appropriate outcome

Day 1	Upper body (Strength)
Day 2	Lower body (Speed work/Quickness)
Day 3	Speed Agility Quickness Drills
Day 4	Lower body (Speed work/Quickness)
Day 5	Speed Agility Quickness Drills

Analysis of Data: To find out the effect of SAQ training on the pre determent variables analysis of co-variants was done for the experiment and control groups. In case of significant f-ratio, LSD was calculated on post hoc measure. The data was processed using SPSS (VERSION 22). The related results and the graphical representation of the data is presented in the chapter.

Balance: Pre and post- test (6 weeks) score of experimental and control group on balance is presented in table no. 1.

Table No. 1

Pre and post (3 weeks) test scores of experimental and control groups on balance.

Group	N	Pre-test		Post-test	
		Mean	SD	Mean	SD
Experimental	10	17.0470	3.12419	21.451	5.94175
Control	10	14.5480	4.42535	12.324	4.80881

The pre and post -test mean of 6 weeks training program on balance indicate that in case of experimental group, the pre and post -test Mean and SD were 17.0470 (3.12419) and 21.451(5.94175). Respectively. In case of control group the pre and post- test Mean and SD were 14.5480(4.42535) and 12.324(4.80881). Respectively

Coupling: Pre and post -test (6 weeks) score of experimental and control group on coupling is presented in table no. 2.

Table No. 2

Group	N	Pre-test		Post-test	
		Mean	SD	Mean	SD
Experimental	10	14.5010	1.49798	11.735	.078157
Control	10	14.6360	2.07138	12.106	1.06848

The pre and post -test mean of 6 weeks training program on coupling indicate that in case of experimental group, the pre and post- test Mean and SD were 14.5010(1.49798) and 11.735(0.078157). Respectively

In case of control group the pre and post -test Mean and SD were 14.6360(2.07138) and 12.106(1.06848). Respectively

Orientation: Pre and post -test (6 weeks) score of experimental and control group on orientation is presented in table no. 3.

Table No. 3

Group	N	Pre-test		Post-test	
		Mean	SD	Mean	SD
Experimental	10	2.4000	1.4298	3.6	0.69921
Control	10	2.0000	1.0540	2.8	1.0328

The pre and post -test mean of 6 weeks training program on orientation indicate that in case of experimental group, the pre and post -test Mean and SD were 2.40 (1.4298) and 3.6(0.69921). Respectively

In case of control group the pre and post -test Mean and SD were 2.00(1.0540) and 2.8(1.0328). Respectively

Rhythm: Pre and post -test (6 weeks) score of experimental and control group on rhythm is presented in table no.4

Table No.4

Group	N	Pre-test		Post-test	
		Mean	SD	Mean	SD
Experimental	10	7.2310	0.66368	6.803	0.56773
Control	10	7.2500	0.57795	7.477	0.56

The pre and post -test mean of 6 weeks training program on rhythm indicate that in case of experimental

group, the pre and post -test Mean and SD were 7.2310 (0.066368) and 6.803(0.56773). Respectively. In case of control group the pre and post -test Mean and SD were 7.25(0.57795) and 7.477(0.56). Respectively

Reaction: Pre and post -test (6 weeks) score of experimental and control group on reaction is presented in table no. 5.

Table No. 5

Group	N	Pre-test		Post-test	
		Mean	SD	Mean	SD
Experimental	10	3.0230	.79944	1.772	0.60426
Control	10	3.3750	1.12594	2.356	1.20057

The pre and post -test mean of 6 weeks training program on reaction indicate that in case of experimental group, the pre and post -test Mean and SD were 3.0230 (0.79944) and 1.772(0.60426). Respectively In case of control group the pre and post -test Mean and SD were 3.3750(1.12594) and 2.356(1.20057). Respectively

Conclusion

The objective of the study was to develop coordinative abilities of players, to develop the coordinative abilities through SAQ drills and to know the effect of SAQ drills on coordinative abilities. There were two groups in the study (Silva[5]; Thomas[6].). The experimental group was under training for compare with the control group which was not in training. The findings of the study is effected on players. According to the findings and the discussion, the effect of SAQ drills on coordinative abilities of cricket players is effective. On the basis of findings and discussion the hypothesis that there would be significant effect of SAQ training on coordinative abilities of cricket players is partially accepted on 2 coordinative abilities depicted significant difference out of selected abilities (Hoff[7]).

Prevalence of Musculoskeletal Disorders among High School Children in Mangaluru

Sushmitha T.[1], Sajjad A.R. Ebrahim[2]

[1]Postgraduate, Yenepoya Physiotherapy College, Irimbanam, Eranakulam, [2]Assistant Professor, Yenepoya Physiotherapy, College, Yenepoya (Deemed to be University), Mangaluru

Abstract

Background: Musculoskeletal Disorders (MSDs) are defined as musculoskeletal symptoms or pain that reflect a number of conditions, which affect the muscles, ligaments, tendons, nerves, bones and joints. The World Health Organization (WHO) commissioned a report describing the impact of impaired musculoskeletal health among the younger population. Anthropometric measures, school bag weight, faulty postures, student- furniture mismatch are some of the common risk factors associated with MSDs among school going children.

Objectives: To find the prevalence of musculoskeletal disorders among high school children in Mangaluru and to find the influence of risk factors for the musculoskeletal disorders.

Study Design: A cross sectional study.

Method: 326 high school children aged 12-16 years from different parts of Mangaluru district participated in the study. A questionnaire was designed to collect the general information. Assessment of the musculoskeletal disorders was done using the Standardized Nordic questionnaire (SNQ).

Results: Out of the 326 students assessed, prevalence of MSDs was found to be 40.2 %. While 40.4 % participants reported of discomfort with the dimensions of the desk and bench, 73.3% of the students cited that they carried heavy bags for at least 5-15 min on a daily basis and 74.8 % of the students stated that they travelled for at least 5 – 15 min of duration on a daily basis.

Conclusion: The prevalence of MSDs among school children was notable. It was also noted that, factors like, school bag weight, anthropometric measures, duration of school bag carriage, duration of travel, mode of transportation to and fro from school, furniture mismatch etc were evident among the population who suffered from MSD. Therefore, preventive and educational activities regarding the MSDs could be included among the population of school children to curb the future complications of these MSDs.

Introduction

Musculoskeletal Disorders (MSDs) are defined as musculoskeletal symptoms or musculoskeletal pain that reflect a number of conditions, which includes a wide range of inflammatory and degenerative conditions affecting the muscles, ligaments, tendons, nerves, bones and joints.[1] Musculoskeletal diseases are prevalent and their impact is wide spread.[2] The occurrence of MSDs are often related to repetitive motion, forceful exertions,

non-neutral body postures and vibration which cause damages to tendons, bones, nerves and other soft tissues.[3] Over 150 diseases and syndromes have been identified to be associated with impaired mobility and function, reduced quality of life and mental well-being.[4] In a systematic analysis done to evaluate the worldwide disease burden and the years lived with disability, low back pain (LBP) was found to be the leading cause of years lived with disability in the world, followed by neck pain and other MSDs in the fourth and fifth place respectively.[5] The World Health Organization (WHO) commissioned a report which described the profound impact of impaired musculoskeletal health on aging among the population.[6] Musculoskeletal problems tend to be recurrent often lasting from adolescence into adulthood. Physical deformities left untreated over time was found to be progressive, causing debilitating consequences.[7, 8]

On an average school children spend at least 5 hours a day at school.[9] A population based study among children and adolescents, had reported a prevalence of MSD which varied between 10- 67%.[10] Another study done among children aged between 5–16 years reported a prevalence of idiopathic musculoskeletal pain of 16.2%. The authors also highlighted the association between the affect of these MSDs on the daily activities and the percentage of absenteeism from school.[11]

A number of studies have proved that school children prone to get musculoskeletal problems, mainly involving the body areas that included the neck, shoulder, upper back, lower back.[12,13,14,15] School bags often consist of books, tiffin box, water bottle and other necessary types of equipment which all the students carry to school. It was reported in a study that 6 out of participants who carried heavy back packs experienced chronic back pain and also reported of upper and mid back pain resulting from changes in posture.[9] Greater bag weight was related to spinal misalignment or curvature, muscle strain and spasms of the back and shoulders.[9] In another study the authors evaluated the effect of backpacks on the lumbar spine in children by performing standing MRI and found that increasing backpack loads significantly compressed lumbar disc and thereby significantly increased lumbar asymmetry.[12] Researchers have also reported that, faulty postures maintained for a prolonged period of time could result in various musculoskeletal illness.[16] Postural deviations are a common problem among children due to long-term poor posture in modern lifestyle. Motorized transportation and lack of regular physical activity are some of the other risk factors associated with postural deviation among children.[17] Mode of transport to and fro from the school is one of the known contributors to MSDs.[13]

In Mangaluru, school children constitute about 21.4 % of the total population. As per Dakshina Kannada statistics (31-3-2016), there were around 272 high schools in Mangalore Thaluk with 32595 students among which 16756 were boys and 15389 were girls.[18] The purpose of this study was to find the prevalence of musculoskeletal problems among high school children in Mangaluru and to find the influence of risk factors associated with MSDs.

Materials and Method

The cross-sectional study included 326 high school students, which was selected randomly from the different parts of Mangalore district. High school students of both the gender, age group between 12 – 16 years were selected randomly (184 boys and 142 girls). Following patients were excluded: (1) Participants under any medication such as antiepileptics, analgesics etc. and (2) participants with the history of previous surgeries/ recent surgeries (involving back, neck, upper limbs and lower limbs). The study was approved by Yenepoya (Deemed to be) University Ethical committee. Children along with the teachers were explained about the purpose of the study. Those who fulfill the criteria were included in the study. Informed consent was given to the parents and an assent was taken from the students. A validated General Performa included the details about each participant such as age, height, weight, bag weight, duration of school bag carriage, method of school bag carriage, duration and mode of travel to and fro from school, duration of sitting hours at school and school furniture discomfort was given to the students. Along with General Performa, SNQ was also given. For a better understanding, questionnaires were translated in to regional language. For the younger students and those who couldn't understand the questionnaire, data were collected orally and filled accordingly. Adequate time was given for the completion of questionnaire and was collected on the subsequent visits.

Height was measured using stadiometer, weight was measured using calibrated weighing machine and school bag weight was measured using portable weight checker. BMI and Bag weight to body weight ratio of each participant was calculated and noted.

Findings:

Table 1: Characteristics of study participants

Characteristics (n = 326)	Mean ± SD
Age (Years)	13.567±0.7147
BMI (kg/m^2)	18.561±3.5349
Bag weight (kg)	4.573±0.9597
Sitting hours (min)	5.471±0.6981

Table 1 shows mean and standard deviation of variables.

Table 2: Prevalence of musculoskeletal disorder (n=326)

Variables	Frequency	Percentage (%)
Musculoskeletal Disorder		
Reported 'Yes' to MSDs	131	40.2
Reported 'No' to MSDs	195	59.8

Table 2 shows the prevalence of musculoskeletal disorders among the participants.

Table 3: Correlation of various factors with prevalence of MSDs

Variables	Frequency	Percentage (%)
Bag weight to body weight ratio		
<10% of body weight	60	45.8
10% - 15% of body weight	57	43.5
>15% of body weight	14	10.7
Duration of school bag carriage		
<10 min	71	54.2
>10 min	60	45.8
Method of bag carriage		
Both shoulder	97	74
One shoulder	34	26
Time taken to school		
<10 min	75	57.2
>10 min	56	42.8
Mode of transport		
Bus	81	61.8
Walk	30	22.9
others	20	15.3
Comfortable using the furniture		
Yes	79	60.3
No	52	39.7

Table 3 shows the frequency and percentage of risk factors considered and its correlation with MSDs.

Table 4: Association between discomforts using existing class room furniture among the participants with musculoskeletal disorder

Variables (n=52)	Frequency	Percentage (%)
Height of the desk	7	13.5
Height of the bench	22	42.3
Distance between desk and bench	2	3.8
All of the above	21	40.4

Table 4 shows the frequency and percentage of variables related to the discomfort using the existing classroom furniture among the participants with MSDs.

Characteristics of participants are depicted in Table 1. A total of 326 participants were included in the study out of which 142 students were girls and 184 were boys. Parameters such as age, Body Mass Index (BMI), bag weight, duration of sitting hours, mean age etc were taken into consideration. The mean age was 13.56 ± 0.17 years, mean BMI was 18.56 ± 3.53 kg/m^2, mean bag weight was 4.53 ± 0.95 kg and the mean sitting hours was 5.41 ± 0.69 min.

Table 2 shows the prevalence of musculoskeletal disorders among the participants. Table 3 shows the risk factors considered during the study and its correlation with musculoskeletal pain. Table 4 shows that 40.4% of the participants with musculoskeletal disorders had discomfort with height of desk, height of bench and the distance between desk and bench. Figure 1 depicts the descriptive statistics of pain around different body sites among the population with MSDs where the participants referred to be suffering from pain at different body sites. Around 30.5 % of the participants cited that that they had neck pain. Some participants cited pain over their shoulder out of which 4.6 % participants specified that they had shoulder pain on the left side, 2.3 % specified shoulder pain on the right side,with 6.9 % participants reporting shoulder pain on both sides. The participants also reported with pain on the elbow and wrist out of which 2.3 % participants specified that they had elbow pain on the left side, 3.1 % participants had elbow pain on the right side. 6.1 % participants specified that they had wrist pain on left side, 7.6% participants had wrist pain on right side and 1.5 % participants reported with wrist pain on both sides. The participants also refereed to other body sites which included 31.3 % with upper back pain, 18.3 % participants had lower back pain, 15.3% reported with pain on the thighs/hips. Besides

this another 35.1% of the participants with MSDs reported with pain on the knees and 26.7 % reported pain on the ankles/feet.

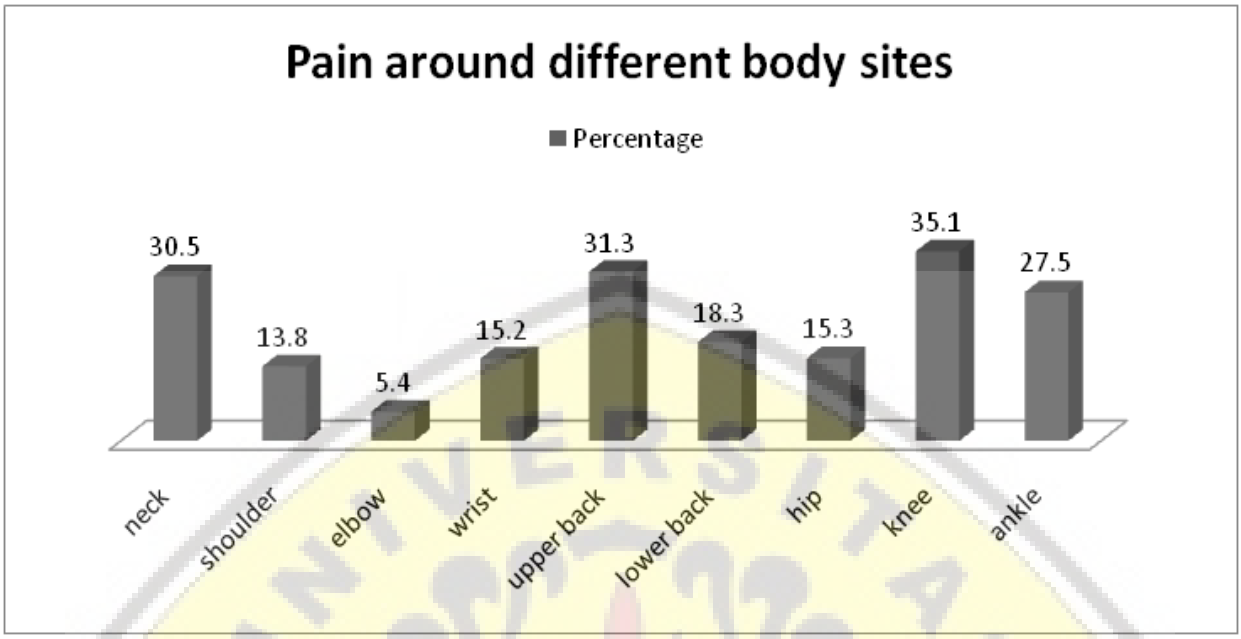

Figure 1: Descriptive statistics of pain around different body sites among the population with MSDs

Figure 1 Shows body region wise analysis of MSDs among the participants.

Conclusion

The present study was done to find the prevalence of MSDs among high schoolchildren between the age group 12 – 16 years in various schools in Mangaluru and also to find the risk factors associated with MSDs. The results showed the prevalence of MSDs among high school children as 40.2 %. The major risk factors associated were school bag weight, duration of school bag carriage, method of school bag carriage, duration of travel mode of transport, duration of sitting hours and furniture mismatch. The higher level of prevalence and association of numerous risk factors pose a need for large scale study among a larger and uniform population with different age category. The findings can be used for awareness program in state and national level, which might be the initial step in prevention of MSDs among school children. The furniture ergonomics can be corrected according to the body dimensions of the students by the help of expert engineers considering the age and the growth patterns of the children. All these initiatives and awareness programs can result in a more active and efficient study environment for students thereby increasing the productivity.

Effectiveness of Benson's Relaxation Therapy on Post Operative Pain among Mothers Delivered by Caesarean Section in a Selected Hospital at Mangaluru

Sweety Theresa D'Souza[1], Janet Prima Miranda[2]

[1]II[md] Year M.Sc. Nursing Student, [2]Associate Professor, Department of Obstetrics and Gynaecological Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Mangaluru, Karnataka, India

Abstract

Background: The effective pain relief is one of the important aspects to in treating patients undergoing caesarean section Untreated pain after surgery may lead to many complications like increased opioid use, postpartum depression and development of persistent pain. Pharmacologic and non-pharmacologic therapy helps in postoperative pain management

Objectives: The objectives of the study were to determine the postoperative pain among mothers delivered by caesarean section, to evaluate the effectiveness of Benson's relaxation therapy on postoperative pain and to associate postoperative pain scores with selected demographic variables.

Method: Quantitative research with quasi-experimental repeated measures design was used. Purposive sampling technique was adopted to select 40 mothers delivered by caesarean section to test effectiveness of Benson's relaxation therapy. The data was collected by using numerical pain rating scale.

Result: The result showed that the mean pre interventional postoperative pain scores of the mothers in the experimental group was 7.90 and in the control group was 8.00 which showed mothers had severe pain both the group. The post intervention pain scores in the experimental group showed there was significant reduction in pain ($p<0.05$) at various time interval. Whereas in the control group also there was significant reduction ($p<0.05$) at various time interval except for 2-12 hour comparison ($p=0.346$).There was no association of pretest postoperative pain scores with selected demographic variables such as age, religion, occupation, monthly income, parity, type of caesarean section and source of information on relaxation therapy in the experimental group and control group ($p>0.05$), except for religion ($p=0.032$) and source of information on relaxation therapy ($p=0.040$) in the control group

Conclusion: Benson's relaxation therapy proved to be effective in reduction of postoperative pain among mothers delivered by caesarean section in selected hospital at Mangaluru.

Keywords: *Postoperative pain;Benson's relaxation therapy; Caesarean section.*

Introduction

Pain is one of the major symptoms in many of the medical condition; one of the most common reasons for seeking medical help.[1] All pain hurts, the resulting sensation is different for different kinds of pain. Surgical pain is the pain caused due to surgical procedure.[2] The effective pain relief is one of the important aspects in treating patients undergoing surgery. The effective pain relief measures have many physiological benefits and

reduce length of hospital stay. Various agents, routes and modes are available for the treatment of postoperative pain management.[3] Complementary and alternative medicine includes various healing approaches and therapies that originate from around the world and that are not based on conventional Western medicine.[4] Relaxation techniques in the forms of breathing exercises, yogic stretching and been used for thousands of years as a part of the ancient religions of Hinduism and Buddhism.[5] Dr. Herbert Benson coined the term 'Relaxation response'. The response is defined as personal ability to encourage the body to release chemicals and brain signals that make the muscles and organs to slow down and increase blood flow to the brain.True relaxations can be achieved by removing oneself from every day thoughts and making an effort to spend some time every day choosing a word, sound, phrase, prayer or by focusing on the breathing. It helps to create inner peace and better health.[6] Although the development of new analgesics and advances have been made in the understanding of pathophysiology of postoperative pain many patients still suffer from moderate to severe postoperative pain.[7]Untreated pain after surgery may lead to many complications like increased opioid use, postpartum depression and development of persistent pain. A pharmacologic and non-pharmacologic therapy helps in postoperative pain management.[8]

Materials and Method

The aim of the study was to assess the effectiveness of Benson's relaxation therapy on postoperative in selected hospital. Quantitative approach with quasi experimental repeated measures design was adopted for the study. Forty subjects were selected by Non-probability purposive sampling technique and were assigned equally to experimental and control group. The postoperative pain was assessed by numerical pain rating scale. Data were analyzed using descriptive and inferential statistics.

Findings: Demographic characteristics of the participants (n=20+20) showed that the majority of the mothers (70%) in the experimental group and control group (55%) belonged to 22-25 years age group. Most of the mother in the experimental group (65%) had higher secondary education whereas the mothers in the control group (50%) had primary education. Most of the mothers both in the experimental and control group (95%, 85%) were homemakers. Majority of the mothers both in the experimental and control group (60%, 55%) belonged to extended type of family. Most of the mothers in the experimental group and control group (40%, 45%) were primiparous. Most of the mothers in the experimental group and control group (70%, 60%) had elective caesarean section. All most all the mothers in the experimental and control group (90% each) had not received any source of information on relaxation therapy for pain. The mean pain score at 2 hrs after caesarean section in the experimental group was 7.90±0.640 and in control group was 8.00±0.725, which showed mothers had severe pain in both the groups (table 1).The mean post intervention pain scores gradually reduced at different time interval but the reduction of pain is apparent in experimental group than in the control group (figure 1). Wilcoxon sign rank analysis showed that there was a significant reduction in the post intervention pain score in the experimental group at various time interval ($p<0.05$). The control group also showed reduction in post intervention pain scores ($p<0.05$) at various time interval except for 2-12 hour comparison ($p=0.346$). Hence it can be concluded that Benson's relaxation therapy had an effect on the experimental group in terms of reduction in postoperative pain at various time interval. Association of the pre-test postoperative pain scores with selected demographic variables showed that there was no association of pre-test postoperative pain scores with selected demographic variables such as age, religion, occupation, monthly income, parity, type of caesarean section and source of information on relaxation therapy in the experimental group and control group, except for religion ($p=0.032$) and source of information on relaxation therapy ($p=0.040$) in the control group.

Table 1: Pre intervention postoperative pain score of the mothers in the experimental group and control group. n=20+20

Group	Min	Max	Max. possible score	Mean±SD
Experimental Group	7	9	10	7.90±0.640
Control Group	7	9	10	8.00±0.725

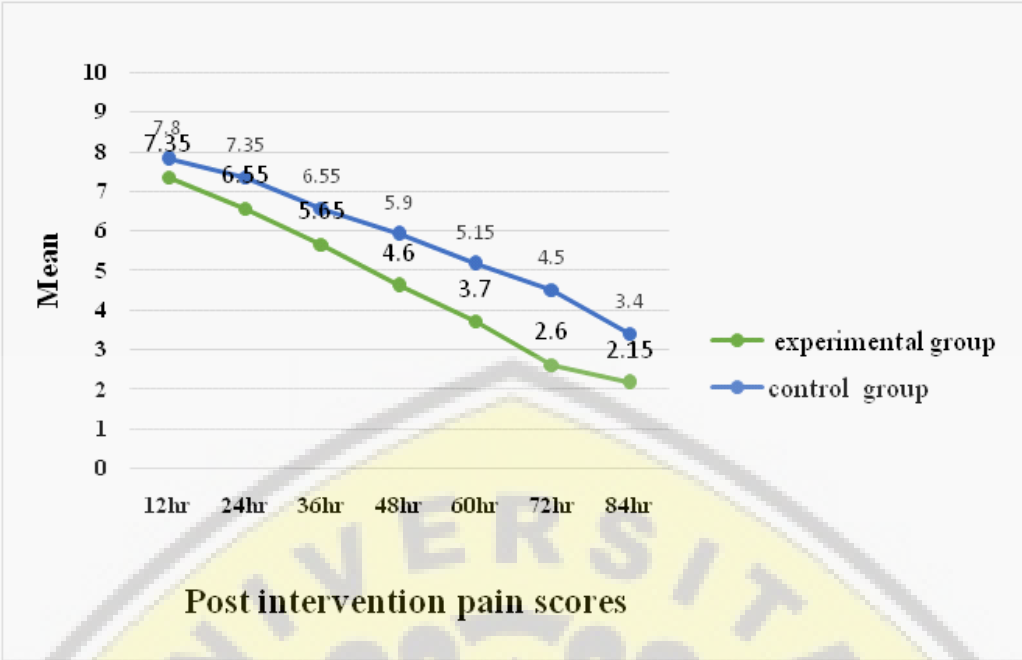

Figure 1: Line graph showing comparison of mean post intervention postoperative pain scores between the experimental group and control group.

Conclusion

The study result showed that Benson's relaxation therapy was effective in reducing the postoperative pain among mothers delivered by caesarean section and it also provided comfort to the mothers in the experimental group. Thus the researcher suggests that there is a need for non pharmacological techniques along with pharmacological method for the postoperative pain management. The researcher recommends that similar study can be done with wider duration with larger group to get a better outcome. There is a need for an extensive and intensive nursing research in the area of postoperative pain management. More researches can be conducted on Benson's relaxation therapy and effectiveness.

Ethical Clearance: Yenepoya Ethics Committee-1 (YEC) approved my study protocol number 2018/101 titled "A study to assess the effectiveness of benson's relaxation therapy on post operative pain among mothers delivered by caesarean section in a selected hospital at Mangaluru" On 11/06/2018 under the chairperson Dr. Vikram Shetty.

Factors Affecting Utilization of Services among Beneficiaries of Janani Suraksha Yojana in Haryana

Tanoja Bachloo[1], Anu Bhardwaj[2], Anshu Mittal[3], Kshitij Chaudhary[4], Shilpi Gupta[2]

[1]Assisstant Professor, [2]Professor, [3]Professor and Head, Maharishi Markandeshwar Institute of Medical Sciences and Research, Mullana (Ambala), [4]Assisstant Professor, Maharishi Markandeshwar Medical College and Hospital, Kumarhatti, Solan

Abstract

Background: The utilization of maternal health care services is an important contributor to the health of the mother and children. Many factors prevent the women from seeking health services.

Objectives: To assess the utilization of maternal health services during antenatal and natal period among JSY beneficiaries and to study the effect of various socio-demographic variables on utilization of these services.

Materials and Method: The present study was undertaken in the rural field practice area of the department of community medicine MMIMSR, Mullana on a sample of 200 beneficiaries who had delivered a child in last one year through house to house survey. Eligible beneficiaries under JSY were interviewed on a pre-designed, pre-tested semi-structured schedule, by house to house visit.

Results: Age group, literacy and BPL card were not found to be significantly associated with more than four antenatal visits. Age group was seen to be significant associated with the place of delivery Association was found to be significant (p0.05)In present study association between place of delivery with Litercay and BPL card holders was not found to be significant ($p > 0.05$)

Conclusion: Many factors affect utilization of Maternal Health services and need to be studied.

Keywords: *Janani Suraksha Yojna,utilization, maternal health services.*

Introduction

Each year, approximately eight million women suffer pregnancy- related complications and over half a million die[1]. of all the maternal deaths 99% occur in developing countries and one third of them are occurring in South East Asian countries[2]. In April 2005, in response to the slow and varied progress in improvement of maternal and neonatal health, the Government of India launched a scheme known as Janani Suraksha Yojna (JSY)[3] under the umbrella of National Rural Health Mission (NRHM). This scheme is an intervention for safe motherhood. JSY is a 100% centrally sponsored scheme and is being implemented in all states and union territories and aimed to reduce maternal and infant mortality by promoting institutional deliveries. NRHM has categorized Haryana among the High Performing State (HPS). The utilization of maternal health care services is an important contributor to the health of the mother and children.Many factors prevent the women from seeking health services. Therefore, this study was done with the objective to assess the utilization of maternal health services during antenatal and natal period among JSY beneficiaries and to study the effect

Corresponding Author:
Dr. Anu Bhardwaj
Department of Community Medicine, Maharishi Markandeshwar Institute of Medical Sciences and Research, Mullana (Ambala), Haryana
e-mail dranubhardwaj78@gmail.com

of various socio-demographic variables on utilization of these services.

Material and Method

A cross sectional study was conducted among beneficiaries of JSY residing in the rural area of Ambala district, Haryana, from January to December -2015

Sample Size: Sample size was calculated using the formula:

$$n = 4pq/L^2$$

where: n = required sample size, p = prevalence, q = 100-p, L = permissible error in estimate of "p"

As our main focus in Janani Suraksha Yojna is on increasing institutional deliveries, so we have used percentage of institutional deliveries for calculating sample size. The percentage of institutional deliveries in Haryana is 74%[4], so the sample size came to be 140, which was rounded of to 200.

The population of District Ambalais served by four C.H.C's. Out of these four C.H.C's one C.H.C was randomly selected. From thechosen the C.H.C, 2 P.H.C's were randomly selected. In each P.H.C., 2 Sub-Centre's were randomly selected. A list of mothers who delivered during last one year (January 2014- December 2014) was obtained from (MPHW-F) and only those entitled under JSY were included in the study. From this list first fifty females, according to date of delivery from all the four sub-centers were selected for the study. Eligible beneficiaries under JSY were interviewed on a pre-designed, pre-tested semi-structured schedule, by house to house visit. Data was entered in Microsoft Excel and analyzed using SPSS version 21. Chi-square test was usedto find the significance of association between maternal health utilization and various socio –demographic variables. Informed consent was taken from the study participants. Permission was taken from Institutional Ethics Committee before the start of the study.

Results

This study was done with the objective to assess the utilization of maternal health services during antenatal and natal period among 200 JSY beneficiaries and to study the effect of various socio-demographic variables on utilization of these services.

Table 1: Association of Antenatal visits with various factors

Age	<4 visits	>4 visits	Total	P value
<25	8 (80.00%)	139 (73.20%)	147 (100%)	0.851
25 -30	2 (20.00%)	48 (25.30%)	50 (100%)	
>30	0 (0.00%)	3 (1.6%)	3 (100%)	
Literacy				
Illiterate	1 (10%)	17 (8.9%)	18 (100%)	0.364
Primary	4 (40%)	48 (25.3%)	52 (100%)	
Secondary	2 (20%)	93 (48.9%)	95 (100%)	
Higher secondary	3 (30%)	27 (14.25%)	30 (100%)	
Graduate	0 (0%)	5 (2.6%)	5 (100%)	
BPL				
Yes	4 (40%)	58 (30.5%)	62 (100%)	0.528
No	6 (60%)	132 (69.5%)	138 (100%)	

(Table 1) shows association of antenatal visits with age group, literacy and BPL status of participating women. In the less than 4 visits category, majority (80%) were in <25 years of age group. Similarly in more than 4 visits category majority (73.2%) were in less than 25 years age group. Age group not found to be significantly associated with more than four antenatal visits In the present study in the category of less than 4 visits, less than half (40%) had education up to primary level, followed by 20% who had education up to middle class and 30% who had studied up to higher secondary. Only 10% women were illiterate in the same category. Similarly in more than 4 visits category, majority (48.9%) had education up to secondary level or middle school, followed by 25.3% who had studied up to primary level, 14.25% who had education up to higher secondary or high school, 8.9% were illiterate and only 2.6% were graduates in the same category. The association of Literacy of women with number of ANC visits was found to be insignificant ($p > 0.05$)On examining association of antenatal visits with BPL card holders it was seen in the category of >4 visits majority 69.5% did not have any card while only 30.5% had card. The association of BPL card holders with ANC visits was not found significant ($p > 0.05$)

Table 2. Association of Place of delivery with various factors.

Variable	Place of Delivery				P value
	Home N(%)	Govt. Hospital N(%)	Private N(%)	Total N(%)	
Age Group					
20-25	0(0.0%)	86(72.3%)	61(79.2%)	147(100%)	.005
25-30	4(100%)	30(25.2%)	16(20.8%)	50(100%)	
30-35	0(0.0%)	3(2.5%)	0(0.0%)	3(100%)	
Literacy of wife					
Illiterate	1(25%)	12(10.1%)	5(6.5%)	18(100%)	.538
Primary	0(0.0%)	27(22.7%)	25(32.5%)	52(100%)	
Secondary	3(75%)	58(48.7%)	34(44.2%)	95(100%)	
Higher secondary	0(0.0%)	18(15.1%)	12(15.6%)	30(100%)	
Graduate	0(0.0%)	4(3.4%)	1(1.3%)	5(100%)	
BPL					
Yes	3(75%)	39(32.8%)	20(26%)	62(100%)	.095
No	1(25%)	80(67.2%)	57(74%)	138(100%)	

(Table 2) shows association of place of delivery with age group of beneficiary. In the category of home delivery all the women were in the age group of 25-30 years where as in the category of gvernment hospital 72.3% were in the age group of 20-25 years. Similarly, in the category of private hospital 79.2% were in age group of 20-25 years. The subjects 58 (48.7%), who delivered in government hospital who had studied up to secondary school, followed by 27 (22.7%) who had studied up to primary school, 18 (15.1%) studied up to higher secondary, 4 (3.4%) were graduate and only 12 (10.1%) were illiterate. 34 (44.2%) studied up to secondary school, 25 (32.5%) studied up to primary school, 12 (15.6%) studied up to higher secondary school. 1 (1.3%) graduate and 5 (6.5%) illiterate, delivered in private hospital. While 3(75.0%) who delivered at home had studied up to secondary level and only 1 (25.0%) women who delivered at home were illiterate. In the present study in the category of home delivery majority 75%had BPL card while 25% did not have any card in the category of government hospital majority 67.2% did not have any card, In the category of private hospital majority 74% did not have any BPL card and only 26% had BPL card.

Discussion

Quality antenatal care is the key to reduce maternal deaths. JSY is a safe motherhood intervention under NRHM. Its main focus is to reduce maternal and infant mortality and morbidity by emphasizing on institutional delivery. It offers cash assistance to the eligible beneficiaries to remove financial barriers hindering access to comprehensive maternity and newborn care.

In order to decrease the information gap in the rural areas of Haryana, this modest (present) study aims to contribute to the data collection. The present study was undertaken in the rural field practice area of the department of community medicine MMIMSR, Mullana .The study population consists of beneficiaries who had delivered a child in last one year. It was conducted on a sample of 200 such females residing in this area through house to house survey during the year 2015 .

On studying association of ANC visits with age group in this study number of visits decreased with the increase of age group despite all having heard about the scheme and increased awareness of the fact that four ANC are must for having healthy mother and healthy baby in the end of pregnancy and simultaneously association was not found to be significant .This decrease may be due to over confidence or experience of the previous pregnancies, This may be young women are motivated easily and older women thinking child birth is a natural phenomenon and do not consider ANC visits

to be necessary . It may be also due to increase of house hold responsibility. However, results were not found to be significant. Similar results were found) in study of Zanib et al.(2001) in Bangladesh it was also found that the overall trend of visiting health facility decreases with the increasing age [5]. In the present study, when relating ANC visits with literacy of women, it was found that number of antenatal visits increased with the literacy of women, however this association was not found to be significant. But in the study of **Kour et al (2015)**[6]it was observed that education had a statistically significant (.006) relation with ANC visits. The positive effects on utilisation are larger for less educated and poorer women by **Jackson et al** 2015,[7] In the present study association of ANC visit with BPL card holders was not found to be significant.

The main focus of JSY Scheme is on institutional delivery. In present study majority (56%) of the deliveries took place in CHC, (38.5%) at private hospital, 2% occurred at home and 1% deliveries took place at sub centre. Whereas, National Family Health Survey-3 (NFHS-3) reported[8], overall rate of institutional delivery in Haryana as 39.4% (Urban 66.7%, Rural 30.3%). A number of national surveys and provincial data sources have demonstrated a steep increase in institutional deliveries both nationally and state-wise since the inception of the JSY program A community based cross-sectional study in Ujjain district, Madhya Pradesh, by Sidney *et al*.,[3] found that 89% of the women had an institutional delivery, out of which 70% deliveries occurred in a CHC and 26% in the district hospital. The present study results are consistent with the findings of Narayan et al.[9] where institutional delivery was found to be 88 % and home delivery 12%. As per report of NHM Haryana 2012 institutional delivery in govt facility were 43.84% and in private hospital were(35.86%). The difference in preference of institution for deliveries may be due to the 24*7 availability and difference in preference for the health institutions.[10]

Summary and Conclusion

This study was a cross-sectional study among 200 JSY beneficiaries to assess the factors affecting the utilization of health services among JSY beneficiaries the utilization of maternal health services. Age group not found to be significantly associated with more than four antenatal visits. The association of Literacy of women with number of ANC visits was found to be insignificant ($p > 0.05$)The association of BPL card holders with ANC visits was not found significant ($p > 0.05$).

Age group was seen associated with the place of delivery Association was found to be significant (p0.05) In present study association between place of delivery and BPL card holders was not found to be significant ($p > 0.05$).

The utilization of maternal and child health services is far from satisfactory in rural India. Hence, to achieve the goal of safe motherhood, future strategies must take cognizance of critical variables. In conclusion, JSY scheme led to high rate of institutional delivery but in present study it was found that people were not aware about the ANC. So as to achieve the 100% results, the motivation, information, education and communication facilities should be increased What is more important is identification of high risk pregnancy and giving them priority care as the main aim of ANC is to reduce MMR, this can be done by ASHA workers by regular visiting the pregnant women to increase the awareness.

Recommendations: JSY scheme aims to reduce the MMR in India by increasing the proportion of institutional deliveries. However, it should be remembered that increasing the institutional deliveries is not the only solution for reducing MMR. What is more important is identification of high risk pregnancy and giving them priority care increasing the proportion of deliveries with skilled birth attendants and appropriate referral facility along with accessibility to health services. It is common experience that at present rate of institutional deliveries, hospital beds have 2-3 pregnant mothers on single bed. Therefore, sufficient attention is needed to be pay to increasing the facilities at hospital, otherwise poor quality delivery care would be worse than current scenario. The JSY scheme also considers deliveries at sub centre as institutional. The deliveries at sub centre cannot be managed properly in case of complications and this would be as good as home delivery and may even worsen the already eroded faith of general population in health system. There is a strong requirement for monitoring and evaluation under JSY to ensure quality services and to prevent corruption.

Knowledge on Practice of Self Perineal Care among Postnatal Mothers in a Selected Hospital at Mangaluru with a View to Develop Information Booklet

Teena Joseph[1], Teesa Theresa Jose[1], Thanooja, Tinsu Titus[1], Tintu Joseph[1], Tinu Suthan[1], Vineetha Suman[1], Amisha S. Amin[2]

[1]IV[th] year B.Sc. Nursing Students, [2]Lecturer, Department of Obstetrics and Gynecological Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be) University Mangaluru, Karnataka, India

Abstract

Objectives of the Study:

- To determine the existing knowledge regarding practice of self perineal care among postnatal mothers.
- To find the association between knowledge scores and selected demographic variables.
- To develop information booklet on self perineal care.

Method: A descriptive study was conducted among 100 postnatal mothers admitted at postnatal ward of selected hospital, Mangaluru. Non-probably convenient techniques was used in the study to select the sample. Structured knowledge questionnaire was used to assess the knowledge of postnatal mothers on self-perineal care.

Results: The study findings showed that majority of the postnatal mothers 55% had average knowledge on self perineal care and has no significant association between the knowledge scores and selected demographic variables.

Conclusion: The study concludes that majority of postnatal mothers has inadequate knowledge regarding self perineal care and hence there is a need to conduct health education programs to enhance the knowledge of postnatal mothers on self perineal care.

Keywords: *Knowledge, Postnatal mothers, Practice, Self perineal care.*

Introduction

Postpartum period is the period during which the woman adjusts, physically and psychologically after child birth.[1] This period is usually considered to be 6 weeks in duration. The postnatal period is a very special time where women undergo the transition into motherhood.[2] An arbitrary time frame divides the period into the immediate postpartum (first 24 hours), early postpartum (first week) and late postpartum (second to sixth weeks). The main goals in postpartum care are to assist and support the woman's recovery to the pre-pregnant state and educate the mother about her own self-care.[3]

In the developing countries the risk of maternal death is 200 times higher than the risk of woman in the developed world. In these countries 99 percent of the estimated 5, 36,000 maternal death has occurred due

Corresponding Author:
Ms. Amisha S. Amin
Lecturer, Department of Obstetrics and Gynecological Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be) University Mangaluru, Karnataka, India
e-mail: amishaamin42@gmail.com

to perineal sepsis. India continues to contribute about a quarter of all worldwide maternal deaths .Maternal mortality rate in India is 230/100000 population and 99 percent are preventable.[4]

A cross sectional study conducted to assess the pattern of maternal mortality in a tertiary level government hospital of a city in north India showed that hemorrhage (37.33 %), pregnancy-induced hypertension including eclampsia (15.55 %) and sepsis (11.11%) were the commonest cause of death following delivery[5].

A study conducted to assess the knowledge and practice on prevention of puerperal sepsis among 100 postnatal mothers in selected hospital, Puducherry showed that only 51% of mothers had adequate knowledge regarding prevention of puerperal sepsis[4].

Proper perineal care is important in preventing infection of the episiotomy, bladder and uterus. Mother should be taught regarding self perineal care, so that she can practice it following discharge from hospital. This promotes healing and provides comfort to the mother. Effective education provides the women with sufficient knowledge to meet their health needs and to seek assistance if necessary. Hence the investigator felt the need to assess the existing knowledge of mothers regarding practice of self perineal care and develop the information booklet to enable the client to participate their own care or needs.

Materials and Method

The study was conducted at a selected hospital of Mangaluru and the hospital was selected based on the feasibility of conducting the study and the availability of the samples. Non-experimental descriptive survey design was adopted. A sample of 100 postnatal mothers were selected by using non-probability convenient sampling technique. A structured knowledge questionnaire regarding practice on self-perineal care was developed by the investigator and was validated by 5 experts in the field of Obstetrics & Gynecology. The tool was then administered to selected 100 postnatal mothers. Collected data was analyzed using descriptive and inferential statistics.

Result and Discussion

Part 1: Demographic characteristics of the postnatal mothers.

Description of demographic characteristics of postnatal mothers: The age distributions of majority postnatal mothers are of 22-25 years. 48% of postnatal mothers have educational status up to PUC. 83% are house wife's, 70% belongs to Muslim religion, 47% of postnatal mothers have 2 children's, 100% of mothers had normal vaginal delivery, 46% are having previous knowledge regarding self perineal care, from family members 33%, friends 2%, health workers 8%, media 3% and 54% are not having previous knowledge regarding self perineal care.

Part 2: To determine the level of knowledge of postnatal mothers regarding self perineal care

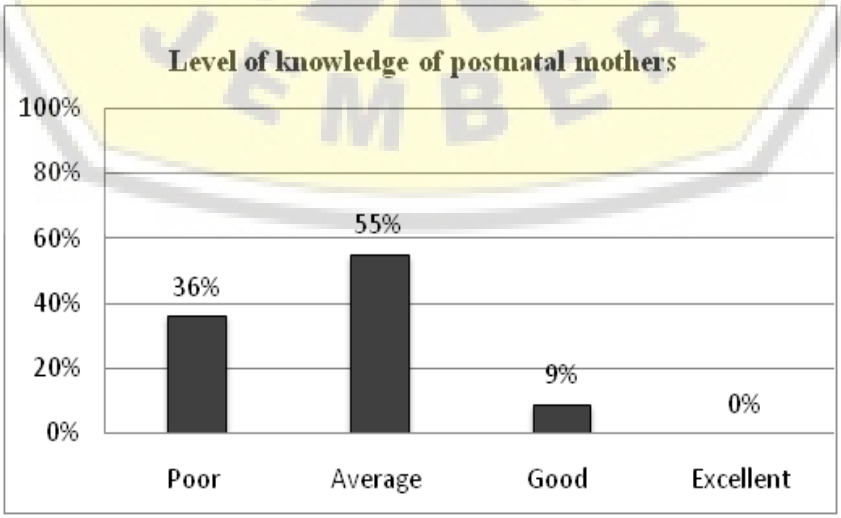

Figure 1: Level of knowledge of postnatal mothers about self perineal care.

The above bar graph shows that majority of the postnatal mothers (55%) had average knowledge on self perineal care, 9% had good knowledge, 36% had poor knowledge and no mothers have excellent knowledge.

Part 3: The above table reveals that the total knowledge score is 20, maximum score was 12 and the minimum knowledge score of postnatal mothers was 2. The mean and median knowledge score is 7.45 and 7.50 respectively with standard deviation 2.341.

Table 1: Mean, median, maximum scores and standard deviation of knowledge score of postnatal mothers regarding self perineal care. n=100

Total Score	Obtained Score				Standard Deviation
	Maximum	Minimum	Mean	Median	
20	12	2	7.45	7.50	2.341

Part 4: In order to find out association between risk scores and selected demographical variable, the following null hypothesis was stated

H_0: There will be no significant association between knowledge score and selected demographic variables.

Table 2: Association between knowledge of postnatal mothers regarding self perineal care and selected demographic variables

Demographical Variables	Chi Square Value	Df	Inference
Age 18-21 years 22-25 years 26-29 years Above 30 years	28.33	30	p=.553 NS
Educational status No formal education Primary PUC Degree & above	28.87	30	p =.524 NS
Occupation House wife Self-employee Government employee Others	18.50	20	p=.554 NS
Religion Muslim Hindu Christian Others	25.43	30	p=.704 NS
Number of children 1 2 3 More than 3	27.42	30	p=.601 NS
Mode of delivery Normal vaginal delivery Vaginal instrumental delivery	18.91	20	p=.527 NS
Previous knowledge Yes No	5.99	10	p= .816 NS
Source of information Family members Friends Health workers Media	42.89	40	p=.348 NS

Table 2 shows that there is no association between the knowledge score of postnatal mothers with the selected demographic variables. Hence the null hypothesis is accepted.

Conclusion

The present study concludes that majority of postnatal mothers has inadequate knowledge on practice of self perineal care. Thus its very important to educate mothers regarding self perineal care and its importance by conducting various health education programmes.

Ethical Clearance: Yenepoya ethics committee-1 approved our study protocol number 2018/076 titled "Knowledge on practice of self-perineal care among postnatal mothers in a selected hospital at Mangaluru with a view to develop information booklet '' on 6/06/2018 under the chairmanship of Dr. Vikram Shetty.

Abstract

Objectives: To study the effect of Buzz Group as a teaching method on academic performance of the students in the teaching in clinical postings and to compare it with the academic performance of students' taught with conventional way of teaching & to further evaluate Buzz group teaching learning method from students' perspective.

Method: An interventional crossover of teaching learning method in which one group was taught using Buzz group teaching and another with the conventional way of teaching, the study was conducted between Jan 2019 to March 2019 in 2 batches of 40 students each and the data was analyzed. The crossover was done as per ethical committee suggestions so as to avoid deprivation of the students from any of the teaching method.

Results: The t value in the Buzz group was significant i.e. 4.667 before crossover and 3.196 after crossover in one batch and 4.604 before crossover and 2.887 after crossover. The overall communication, learning, problem solving, communication and score for Buzz group teaching was compared to conventional way of teaching and the results were statistically significant. The problem solving in the Buzz group teaching shown t-value of 14.701 of significance.

Conclusion: The results suggest that Buzz group teaching is clearly better than the conventional classroom teaching and is in coherence with the MCI guideline of Competency Based Medical Education (CBME) guidelines. This method of teaching requires minimal additional efforts and its inclusion in few of the Clinical postings could prove equally effective

Keywords: *Buzz Group; Teaching Learning Method; Peer assisted Learning.*

Introduction

"*A wise man learns from experience and an even wiser man from the experience of others.*"

Medical knowledge is vast knowledge in true sense and therefore the time period for learning it is obviously meager. Both the student of the medical education as well as the teacher has to utilize the available time with their best potential for attaining maximum knowledge and skills in the available time frame[1].

It has been observed that student's attention wanders in class. It may wander from the very next minute teacher start teaching due to various reasons ranging from loss of interest in subject, feeling of being in alien world, no interaction with teachers, no immediate feedback or teacher's critical evaluation, to feeling of less knowledge and loss of confidence for active participation.[2]

Corresponding Author:
P.M. Durgawale
Associate Professor Dept of Community Medicine, Krishna Institute of Medical Sciences Deemed to be University, Karad

These various reasons hinder the teaching in classrooms as well as clinical postings where teacher already has to fight against time crunch for completing the teaching. These problems make a good teacher bring in some innovative ideas so that the student will always be on their toes to actively participate or listen. One of the better innovative ideas probably underutilized is Buzz group teaching.

Buzz Group is a large group divided into several small groups, consisting of 4-5 people. The place is arranged so that students can seat face to face and exchange ideas easily. The discussion can be done in the middle or at the end of the lesson with the intention of sharpening the framework of the lesson material, clarifying the lesson material, or answering questions[3]. With Buzz group of teaching each question answered by the group is by sharing and discussing their knowledge with teammate colleague which is equal to separate teaching of the student who doesn't know the answer; this ultimately saves lot of time and energy in individual teaching sessions.

According to the definition of BUZZ GROUP by UNICEF[4]: Buzz Groups are a method for quickly and efficiently gathering feedback on a topic or responding to a specific question during a plenary (a session that includes all participants of an event). Without moving from their seats, participants form mini-clusters of two or three people and engage in free discussion – or 'buzz'– for a few minutes on a given question. Buzz Groups provide a welcome change of pace for participants, helping to enliven and energize large group meetings and events.

- **First "buzz groups" was used by Dr. Donald Phillips at Michigan State University**

Variations of the Buzz Group[4,5]: There have been number of different method by which Buzz group can be used viz. Phillips 66 Method, Clark's 22 Method, Huddle Method, Circular Response Method, Progressive Buzz Sessions

Uses of buzz group[6]: Buzz group have numerous advantages as it can be used at any time throughout the program, particularly when you want trainees to become actively engaged with the issues. Even it can be used prior to a lecture to determine what is already known about a topic. It can be used to intersperse a lectureto foster comprehension and bring out questions, with this you can conclude a lecture by asking groups to integrate new information with previous learning even after a difficult session, BUZZ GROUPS could be asked to collect questions and issues that need clarification.

Advantages of buzz group[7]: It allows everyone's ideas to be expressed, Participants learn to work in real-life situations where others' opinions are considered, It sets the groundwork to get discussion started, as members actively participate its good for dealing controversial subject.

We planned the study with the following objectives.

Objectives:

1. To study the effect of Buzz Group teaching on academic performance of the students in the teaching in clinical postings.
2. To evaluate Buzz group teaching learning method from students' perspective.
3. To compare the academic performance of students' undergoing teaching with Buzz group teaching method with the academic performance of students' taught with conventional way of teaching.

Methodology

Study Design: Interventional study.

Study Subjects: 3rd year 1st term MBBS students.

Sample Size: Two Batches of 40 MBBS 3rd year 1st term MBBS students which make it 80 students in total will be included for study.

Type of Study: Crossover study.

Study Duration: 3 Months.

Ethical Committee Permission: This being an interventional study, ethical committee permission was obtained and crossover of the students so that each student will have equal exposure to both the teaching learning method was done as suggested by the committee.

Process: Each Batch of 40 students was grouped in two different group viz. Group 'A' and Group 'B'. The students in Group A were again grouped in number of 4 students in one group randomly so as to make 5 groups from 20 students. The students were now working as team instead of a single individual following the principals of Buzz group teaching. The questions asked to their team were now answered by the team, after discussion amongst themselves and

using their individual knowledge in tandem! Here each question answered is by sharing and discussing their knowledge with teammate colleague which is equal to separate teaching of the student who doesn't know the answer; this ultimately saves lot of time and energy in individual teaching sessions. The other group B of 20 students had undergone the teaching the traditional way. After 5 case discussions both the students group were subjected to OSCE with set of formulated questionnaire. The assessment was so planned so as to assess their cognitive, affective and psychomotor domain and record their overall performance. In the next second half of the posting crossover of the students group was done and Group A was undergoing the posting traditional way whereas the Group B was subjected to Buzz group of teaching. These two groups after 5 case discussions were assessed with another set of formulated questionnaire and their performance was recorded.

The students' individual perception was recorded at the end of the posting on likerts scale of 1-5 for different questions like communication, learning, expression of ideas, Problem solving and overall perception about the teaching learning method.

These both the records were analyzed using Mann- Whitney test, Paired t test. Both the groups after completion of study will be again subjected to set of self reporting questionnaire where they will be asked close ended and a few open ended questions which will assess their individual perception about the new teaching method.

Table 1: Result of Batch - 1

Group A (Buzz Group)		Groupb (Conventionalgroup)	
Roll No	**Marks**	**Roll No**	**Marks**
1	22	21	21
2	23	22	16
3	24	23	18
4	21	24	17
5	24	25	17
6	18	26	16
7	22	27	18
8	26	28	20
9	21	29	23
10	22	30	21
11	17	31	17
12	18	32	15
13	24	33	15
14	23	34	16
15	22	35	17
16	16	36	18
17	19	37	15
18	23	38	22
19	22	39	16
20	21	40	15

When two groups were compared, it is clearly seen that performance of GROUP A students was statistically extremely significant with the t value 4.667 which can be interpreted as the BUZZ GROUP of teaching has significantly shown improved students' academic performance as compared to conventional method of teaching

Table 2: Result of Batch – 1 After Crossover

Group A (Conventional Group)		Group B (Buzz Group)	
Roll No	**Marks**	**Roll No**	**Marks**
21	24	1	18
22	21	2	17
23	22	3	17
24	20	4	18
25	20	5	20
26	20	6	17
27	19	7	19
28	23	8	23
29	26	9	18
30	24	10	16
31	22	11	19
32	19	12	22
33	19	13	21
34	19	14	17
35	21	15	15
36	18	16	15
37	17	17	16
38	24	18	20
39	17	19	19
40	18	20	18

When two groups are compared, it is clearly seen that performance of GROUP A students was statistically very significant with the t value 3.196 which can be interpreted as the BUZZ GROUP of teaching has significantly shown improved students' academic performance as compared to conventional method of teaching

After the cross over when GROUP B was taught using BUZZ GROUP METHOD they have shown improved performance but the difference was slightly less than the previous group. Probably, now both the groups have gone undergone Buzz group teaching method. Therefore, Buzz group teaching method has improved the performance significantly.

The results of Batch 2 were as follows:

Table 3: Result of Batch–2

Group A (Buzz Group)		Group B (Conventional Group)	
Roll No	**Marks**	**Roll No.**	**Marks**
41	16	61	19
42	27	62	16
43	18	63	18
44	18	64	18
45	18	65	17
46	21	66	16
47	24	67	18
48	21	68	20

Group A (Buzz Group)		Group B (Conventional Group)	
Roll No	**Marks**	**Roll No.**	**Marks**
49	18	69	22
50	22	70	21
51	23	71	17
52	22	72	16
53	22	73	16
54	23	74	16
55	19	75	17
56	20	76	18
57	24	77	15
58	23	78	22
59	24	79	17
60	24	80	16

When two groups were compared, it is clearly seen that performance of GROUP A students was statistically extremely significant with the t value 4.604 which can be interpreted as the BUZZ GROUP of teaching has significantly shown improved students' academic performance as compared to conventional method of teaching.

Table 4: Result of Batch – 2 After Crossover

Group A (Conventional Group)		Group B (Buzz Group)	
Roll No	**Marks**	**Roll No.**	**Marks**
41	17	61	16
42	24	62	22
43	18	63	20
44	18	64	21
45	20	65	18
46	16	66	21
47	22	67	22
48	20	68	23
49	22	69	19
50	19	70	22
51	17	71	21
52	16	72	22
53	17	73	22
54	16	74	20
55	17	75	19
56	18	76	20
57	21	77	19
58	22	78	23
59	17	79	21
60	16	80	21

When two groups were compared, it is clearly seen that performance of GROUP A students was statistically very significant with the t value 2.887 which can be interpreted as the BUZZ GROUP of teaching has significantly shown improved students' academic performance as compared to conventional method of teaching.

After the cross over when GROUP B was taught using BUZZ GROUP METHOD they have shown improved performance but the difference was slightly less than the previous group. Probably, now both the groups have gone undergone Buzz group teaching method. Therefore, Buzz group teaching method has improved the performance significantly.

Student's perception about BUZZ group vs CONVENTIONAL group of teaching: The following questions were asked to the students who underwent the study. They were asked to rate the study on the basis of these 5 criteria. The criteria are as follows:

A= COMMUNICATION IN GROUP
B= LEARNING
C= EXPRESSION OF IDEAS
D= PROBLEM SOLVING
E= OVERALL SCORE

The feedback of the same is represented in a table form given below.

Table 5: The comparison ratings as per OVERALL SCORING IN GROUP between buzz group method and conventional study method for Batch 1 (Roll no 1-40) is given below.

	Buzz Group	Conventional Group
Mean	4.55	3.35
Minimum Value	3.0	3.0
Maximum Value	5.0	4.0
t-value	9.883	

Table findings suggest that the mean value of the buzz group is 4.55 & the mean value of conventional teaching is 3.35. The buzz group ratings are higher than that of conventional group. Thus, comparing the t-value= 9.883 between them shows SIGNIFICANT variation.

The analysis of Table 5 clearly supports that Buzz group is better than Conventional group. The author Tagor Pangaribuan[8] published in research gate and**Muntaha Muntaha**[9] in his studyfound that Buzz group technique is effective for students having low self-esteem. The **author Yuni Indah Novita Sari** in their study at Kediri University **Project**[10] published in Artikel Skripsi found that the Project Based Learning gave significant effect to the students' writing ability, The authors Elisabeth Milaningrum in**Smpn 1 Jaten Karnganyar Project**[11] & Inoue Tetsuro in their study **Testuro Inoue Project.**[12]respectively published in Information Centre Jurnal Sains Terapan & Education Research found that the introduction of Buzz Learning techniques at the junior high school level has resulted in dramatically improved reading ability, an augmented ability to learn by themselves, fewer students with inferiority complexes and students learning out of curiosity rather than just obligation. Teaching, reading using Buzz Group method to the students of SMPN1 Jaten Karanganyar is more effective than one of those having direct instruction method.

Table 6: The comparison ratings as per OVERALL SCORING IN GROUP between buzz group method and conventional study method for Batch 2 (Roll no 41-80) is given below.

	Buzz Group	Conventional Group
Mean	4.55	3.325
Minimum Value	3.0	3.0
Maximum Value	5.0	4.0
t-value	10.161	

Shows that the mean value of the buzz group is 4.55 & the mean value of conventional teaching is 3.325. The buzz group ratings are higher than that of conventional group. Thus, comparing the t-value= 10.161 between them shows SIGNIFICANT variation.

The findings of the second batch of the students is comparably similar indicating that the Buzz group of teaching is better than the conventional way of teaching!

Conclusion

- From the above obtained results, it is clear that BUZZ group method of teaching is preferred by the students over the CONVENTIONAL method using the peer learning (BUZZ group) method.
- There are certain constraints of Buzz group teaching like the facilitator needs to actively tackle buzzing in group but this type of teaching, certainly, can be equally effective if used in some of the case discussions, if not possible in all.

- MCI is now proposing CBME (Competency Based Medical Education) and this type of teaching would be a method of choice for better implementation of CBME in clinical postings.

Implication: The study findings can help formulate the teaching time table with inclusion of Buzz group teaching in few clinical posting time tables since it will improve students' performance and it is in coherence with the MCI recommendations of CBME.

Acknowledgement: We are thankful to the Community Medicine department staff members because of their active involvement and participation. It is because of this that the study was satisfactorily carried out.

Assessment of Diabetes Risk and the Factors Associated in Adult Population Using Indian Diabetes Risk Score: A Community Based Study in Coastal Andhra Pradesh

V. Sarada[1], B. Subbarayudu[2], C. Rajyalakshmi[3]

[1]Assistant Professor, Community Medicine, GITAM Institute of Medical Sciences and Research (GIMSR), Visakhapatnam, Andhra Pradesh, India, [2]Associate Professor, General Medicine, GIMSR, [3]Assistant Professor, Community Medicine, GIMSR

Abstract

Introduction: Diabetes is the chronic metabolic disease with rising prevalence in low and middle income countries. According to WHO diabetes is the seventh leading cause of death in 2016 and is major cause for complications like cardiovascular diseases and stroke. Hence, early identification of people at risk of diabetes is required to reduce the disease burden.

Objectives: To assess the diabetes risk among the adult population using Indian Diabetes Risk Score. To identify the factors associated with the diabetes risk score.

Materials and Method: A community based cross sectional study was done in an urban resettlement colony to identify the people at risk of developing type 2 diabetes .Indian Diabetes Risk Score was used to identify at risk individuals. The study subjects were categorized into low, medium, high risk groups based on IDRS scores .Random blood sugar levels of subjects were obtained at time of data collection after taking informed consent. The data was entered in Microsoft Excel and analyzed by using SPSS version 21. Chisquare test was used to find any significant association between socio-demographic profile, RBS values and risk categories.

Results: In the study among 129 subjects,64.3 % were males, 35.7% were females. IDRS scores indicate 12(9.3%) were in the low risk, 53(41%) were in medium risk and 64 (49.7%) were in high risk category. About 21.7% had Random blood sugar values ≥200mg/dl at the time of study. There was significant association between RBS values and IDRS.

Conclusion: The present study showed that majority of subjects were in medium and high risk categories. Hence, the study recommended life style modification and further monitoring of blood glucose levels to prevent the risk of development of diabetes.

Keywords: *adult population, community, diabetes risk, Indian Diabetes risk score, Coastal Andhra Pradesh.*

Introduction

Non-communicable diseases (NCDs), including heart disease, stroke, cancer, diabetes and chronic lung disease, are collectively responsible for almost 70% of all deaths worldwide. Almost three quarters of all NCD deaths and 82% of the 16 million people who died prematurely, or before reaching 70 years of age, occur in low- and middle-income countries.[1] The rise of NCDs has been driven by non- modifiable risk factors like age, gender, family history and modifiable risk factors tobacco use, physical inactivity, the harmful use of alcohol and unhealthy diets. Thus for NCD principles of primordial, primary prevention have to be applied for early detection of risk factors. These lead to identification

Corresponding Author:
Dr. Boda Subbarayudu
Associate Professor, General Medicine, GIMSR

of "Risk Scores or Tests". Several diabetic risk scores have been devised for the last decade for prevention programs in the USA, Scandinavia and U.K.[2,3] All these scores are useful mass screening tools which are based on population based criteria from the respective countries. Mohan et al group from the Chennai Urban Rural Epidemiology Study (CURES) have attempted to develop a simple user friendly Indian Diabetes Risk Score.[4]

India currently represents 49% of the world's diabetes burden, with an estimated 72 million cases in 2017, a figure expected to almost double to 134 million by 2025. Diabetes prevalence has increased by 64% across India.[5,6] Up to 2 % of women aged 15-19 years and 2.6 % aged 20-25 years had high or very high blood glucose levels. In men, this rose to 2.9 % and 3.7 %, respectively (NFHS 2015-16). Currently, 1 in 4 under age 25 years has adult-onset diabetes.[7,8] Challenges like early-onset diabetes, genetically predisposition, poverty, illiteracy, non-adherence to diabetic management etc indicate that diabetes must be carefully screened and monitored regardless of patient age within India.[9,10] About 66% of Indian Diabetics are not diagnosed as compared to 50% in Europe and 33% in USA. There is a need to unmask hidden burden of the disease. The IDRS has a sensitivity of 72.5% and specificity of 60.1% and is derived based on the largest population based study on diabetes in India CURES.[11,12] IDRS uses two modifiable risk factors (waist circumference and physical inactivity) and two non-modifiable risk factors (age and family history of diabetes), providing a clear message that if modifiable risk factors are altered, the risk score can be considerably reduced. This score may be incorporated into the proposed Indian National Diabetes Program and surveillance studies on NCD by WHO and ICMR.[13]. Hence the present study was conducted to assess risk for diabetes among adult population using IDRS.

Objectives:

1. To assess the diabetes risk among the adult population using Indian Diabetes Risk Score.
2. To identify the factors associated with the diabetes risk score.

Materials and Method

Study design: A Community based cross-sectional study.

Study setting: Urban resettlement colony in the urban field practice area of GITAM Institute of Medical Sciences and Research, Visakhapatnam, Coastal Andhra Pradesh.

Study period: January-February 2019

Sample size: 129

Sampling method: Purposive sampling

Procedure of data collection: An urban resettlement colony was selected for the study in the urban filed practice area of GITAM Institute of Medical Sciences and Research, Visakhapatnam. A regular free medical camp was conducted in the area in the month of January 2019. The study participants were selected from the population attending the camp based on inclusion and exclusion criteria. Data was collected using a Questionnaire including variables related to Socio-demographic profile and Indian Diabetes Risk Score(IDRS). The IDRS was based on four simple parameters namely age, abdominal obesity, family history of diabetes and physical activity. The information for these risk factors was obtained based on four simple questions and one anthropometric measurement namely waist circumference .Subjects with an IDRSvalue of ≥60 was categorized as high risk, 30-50 moderate and,<30 as low risk.The purpose of the study was explained andinformed consent was taken from the subjects. Socio-economic status was assessed by using Modified kuppuswamy scale for 2019.The height, waist and hip circumference of the study subjects were measured in centimeters by using a non- stretchable measuring tape following WHO STEPS protocol.[14] The weight was measured in kilograms with the help of standardized weighing scale. BMI, WHR were calculated. The blood pressure of the participants was measured using a standardized sphygmomanometer in mmHg and BP ≥140/90 is considered as hypertensive according toJNC VII classification.[15] The levels of the Random blood sugar (RBS) of the participants were detected at the time of data collection by using standard glucometer.

Inclusion Criteria:

1. All persons attending camp with age>18 years.
2. Those who are not clinically diagnosed as having diabetes.
3. Those who are willing to participate in the study.

Exclusion Criteria:

1. Those who are already diagnosed to have diabetes.

2. Pregnant women, chronically ill patients.
3. Those who are not willing to participate in the study.

Statistical method: Data was entered in Microsoft Excel and analyzed by using SPSS software version 21. Chi-square test was used to test the association between categorical variables and $p<0.05$ was taken significant.

Results

About 129 subjects participated in the present study. **Table no 1** represents the socio-demographic profile of the participants. The study subjects were in the age group of 22 to 65 years of age with mean age 39.71 years and SD= 12.211. Among the study participants 64.3 % were males, 35.7% were females. The distribution of participants based on education, occupation, socio-economic status is shown in **Table no 2**.

The distribution of the subjects based on WHO cut off values (Asian standards) for BMI and anthropometry for men and women is represented in the **Table no 3.** Among males (n=83), 62.66% had waist circumference ≥90 cm and 55.4% had waist hip ratio >0.9. Among females (n=46),82.6% had waist circumference ≥80 cm and 43.48% had waist hip ratio >0.85. Among the participants 42.6% were obese based on BMI.

About 14.7% of the men were current smokers and 10.1% were current alcoholics. In the study participants 10.1 % were known hypertensive. About 14% of the individuals had blood pressure ≥140/90 and 21.7% had Random blood sugar values ≥200mg/dl at the time of study as shown in **Table no 4**.

The distribution of the study subjects into low, medium, high risk groups based on their IDRS scores is shown in **Figure no. 1.** Out of 129, 12(9.3%) were in the low risk, 53(41%) were in medium risk and 64 (49.7%) were in high risk category.

The study showed no significant association between socio-demographic variables and IDRS categories. The study participants were categorized into two categories based on their RBS values as individuals with RBS ≥200mg/dl and others with ≤200mg/dl. Chi-square test was done to find any significant association between RBS values and IDRS.The study showed a significant association between RBS values and IDRS as shown in Table no. 5.

Table no 1: Socio-demographic profile of participants (N=129)

Discussion

The present study was done among 129 subjects to identify the risk of development of diabetes by using IDRS. Although various risk factor scoring systems (Ramachandran et al)[16] were developed previously, IDRS developed by Mohan *et al*[4] is considered simple, fast, inexpensive, non-invasive and reliable tool toidentify individuals at high risk of type 2 diabetes which has been previously validated by other researchers in India. The IDRS scoring system clearly indicates that the risk of development of diabetes can be minimized by modifying the modifiable risk factors. In the study,out of 129, 12(9.3%) were in the low risk, 53(41%) were in medium risk and 64 (49.7%) were in high risk category. Similarly in the studies done by Mohan V et al[4] in Chennai city, Gupta et al [17] in urban Pondicherry, Nagalingam S[18] et al in semi urban area of Tamil Nadu the study subjects in high risk group were 43%,31%,37% respectively. In the studies done by Randip C et al[19] in rural West Bengal and Brinda P et al[20] in rural Karnataka the population in the high risk category were 31.5% and 25.7% respectively. The differences in the risk score among different studies might be due to differences in socio demographic profiles.

In the study, subjects were tested for RBS levels as it is the most convenient method and can be done in large scale at any time of the day depending on availability of the person and does not need venipuncture. In the present study 31.25% of the subjects in high risk group were having RBS ≥200 .Similarly in the studies done by Sumana M et al [21] andArun A et al[22] 35 % and 47% of the high risk group were having RBS ≥200 respectively .Thus validating IDRS .Various other studies were done (Vardhan A et al, Stanley JML et al, Adhikari P et al)[23-25] validating the IDRS score. Hence IDRS tool is cost effective in screening risk of type 2 diabetes in a developing country like India with rising burden of diabetes and where most of the people are unaware of their diabetes status.

Conclusion

In the present study majority of the participants were in medium and high risk categories based on IDRS scores. The study showed significant association between RBS values and the IDRS. Hence the study showed that IDRS is a cost effective mass screening tool for early identification of people at the risk of developing diabetes.

Recommendations: All the subjects with RBS value more than the cut-off were advised to undergo further confirmatory test and follow up for diabetes. Those who belonged to IDRS moderate and high risk categories were advised lifestyle modifications and dietary changes. Those who were in the low risk category were advised health promotion activities.

Evaluation of Proportion of Children (0-18 Yrs) Identified and Underwent Surgery for Congenital Heart Diseases Under the Rashtriya Bal Swasthya Karyakram (RBSK), Program in District Thane, Maharashtra State

Vijay Bawiskar[1], Prasad Bhandari[2], Kailas Pawar[3]

[1]Joint Director, Maharashtra State AIDS Control Society, Govt. of Maharashtra, [2]Orthopaedic Surgeon Class 1 Civil Hospital, Thane, Govt. of Maharashtra, [3]Civil Surgeon, Civil Hospital, Thane, Govt. of Maharashtra,

Abstract

Under National Rural Health Mission, significant progress has been made in reducing mortality in children over the last fourteen years (2005-19). Whereas there is an advance in reducing child mortality there is a dire need to improving survival outcome. This would be reached by early detection and management of conditions that were not addressed comprehensively in the past.

Rashtriya Bal Swasthya Karyakram (RBSK) is an important initiative aiming at early identification and early intervention for children from birth to 18 years to cover 4 'D's viz.

Defects at birth, Deficiencies, Diseases, Development delays including disability.

The services aim to cover children of 0-6 years of age in rural areas and urban slums in addition to children enrolled in classes 1st to 12th in Government and Government aided Schools.

Child screening under RBSK is at two levels community level and facility level. While facility based new born screening at public health facilities like PHCs/CHCs/DH, will be by existing health manpower like Medical Officers, Staff Nurses & ANMs, the community level screening will be conducted by the Mobile health teams at AnganwadiCentres and Government and Government aided Schools.

Keywords: *Rashtriya Bal Swasthya Karyakram (RBSK), Heart Surgeries, Thane District.*

Introduction

The Ministry of Health & Family Welfare, Government of India, under the National Health Mission, NHM launched the Rashtriya Bal Swasthya Karyakram (RBSK), that executes 'Child Health Screening' and 'Early Intervention Services', a systemic approach of early identification and link to care, support and treatment[(1)]. It started health screening of school children in the age group of 6-18 years through the 'School Health Program' SHP in 2008[(1)]. The RBSK aids early detection and management of defects at birth, diseases in children, deficiency conditions and developmental delays including disabilities prevalent in children[(2)]. It was initiated in 2013 and has been implemented in 33 districts of Maharashtra[(3)]. A team comprising 2 medical officer (one male & one female), one ANM and one Pharmacist is deputed under the supervision of medical superintendent in each district for the said purpose[(3)]. The team screens children from anganwadicenters and schools. After screening, children identified with

Corresponding Author:
Dr. Vijay Bawiskar
Joint Director, Maharashtra State AIDS Control Society, Govt. of Maharashtra,
e-mail: infoquality2020@gmail.com

defects, deficiencies, diseases and developmental delays are referred to the Rural Hospital/Sub District Hospital/ District Hospital or the specified referral center for further treatment[3].

The initiative is estimated to benefit 270 million children attending anganwadi centres and schools in a phased manner[1]. An effective health intervention will reduce both direct costs and out-of-pocket expenditure[4]. Child Health Screening and Early Intervention Services also aims at reducing the extent of disability, at improving the quality of life and enabling all persons to achieve their full potential[5].

After screening the next vital step is confirmation of preliminary findings, referral support and management and follow ups. Under RBSK, these activities viz. confirmation, management, referral, tracking & follow-up, needs to be planned according to the age group of the child[1].

The burden of pediatric heart disease in India is largest as compared to other countries because the population of children is highest in the world[6]. Two recent studies at birth have given estimation of congenital heart disease (CHD) in India. Approximately 100,000 babies are born each year with "major" and "critical" CHD[4]. These CHDs include a list of conditions that need to be addressed early, mostly within the 1st year of life. Such cases do not receive timely treatment, because of which the morbidity and mortality burden is high.

It is essential that the cases are identified early so that they could be referred and treated promptly. So, a research study was planned with an objective to find out number of children identified with heart diseases and operated for heart surgeries, through the RBSK initiative in the district of Thane in the rural, municipal council and nagarpalika area during the year 2018-2019. The study would be helpful in understanding the proportion percentage of children receiving treatment after identification of CHD and the reasons for not undergoing the treatment.

Method

Data of all the children screened under RBSK screening programme was collected from district early intervention centre of Anganwadi Centres (AWC), School Health Program (SHP). The data is from three regions of Thane District. Secondary data of the year 2018-2019 was obtained with due approval from the concerned authority. The data was analysed using excel spread sheets. It was on number of cases identified, cases operated and the different reasons for non- conduct of the heart surgeries.

Population Setting: Thane is one of the largest and advanced districts in the state of Maharashtra. It lies on the North of Konkan division. According to census 2011, it is third in the state in terms of population. The industrial areas developed in Thane, Kalyan, Ulhasnagar, Ambernath, Bhiwandi talukas of the district are close to Mumbai. Marine fishing, groundwater fishing is done as well. In terms of industrial development Thane district is third in the state. Industrialization has brought economic and social development of the district. Maharashtra Industrial Development Corporation has developed 8 industrial estates. Access to the ports at Mumbai, international market, development in communications and the facilities provided by the government has made the district prosperous. Especially in the southern and western parts of the district, there is a centralization of industries[7].

Results

Table 1: Proportionate distribution of identified and conducted heart surgeries through RBSK in the year 2018-2019 in Thane district

	AWC/School	Identified	% to Total Cases	Conducted	Not done	% to Total not done
Rural	AWC	53		49 (92.45%)	4 (7.55%)	26.66%
	SHP	23		17 (73.91%)	6 (26.07%)	40.00%
	Total	76	58.46%	66 (57.39%)	10	66.66%
MNC	AWC	33		33 (100%)	0(0%)	0%
	SHP	17		14 (82.35%)	3 (17.64%)	20.00%
	Total	50	38.46%	47(40.86%)	3	

	AWC/School	Identified	% to Total Cases	Conducted	Not done	% to Total not done
NP	AWC	2		2 (100%)	0(0%)	0%
	SHP	2		0 (0%)	2 (100%)	13.33%
	Total	4	3.07%	2 (1.73%)	2	
Total	AWC	88		84	4	
	SHP	42		31	11	
Grand Total		130		115(88.46%)	15(11.54%)	

*AWC- Anganwadi Center *SHP-School Health Program * MNP- MahaNagarPalika, NP- NagarPalika,

Table 1 reflects that out of the total 130 cases identified majority (n=76, 58.46%) were from rural area as compared to MNC (38.46%) and NP (3.07%) area.

Similarly, highest number of heart surgeries (n=66, 57.39%) were conducted in the same group as compared to MNC (40.86%) and NP (1.73%) area.

As such, the contribution of total number of identified cases and operated cases from NP area is significantly low.

Out of the Total 130 cases identified for Heart surgery, in 115 cases (88.46%) surgery was performed and in 15 cases (11.54%) surgery could not be performed due to various reasons.

On further analysis it is revealed that out of 15 cases in which the surgery could not be performed, the cases from Rural Area were 10 (66.66%), the cases from MNP and NP area being 20.00% and 13.33% respectively. The analysis also reveals that out of these 10 cases, 4 cases (40%) are on follow up for Surgery and 6 (60%) are put on medicines only. The proportion of cases from Rural Area in whom surgery has not been performed poses a great public health concern.

Discussion

With a child population of over 400 million, India has the largest number of children between the ages of 0-18 years globally. The indicators are a cause of concern, as India contributes 20% to global child deaths [8]. The birth defects prevalence varies from 61 to 69.9 per 1000 live births [9]. To address child health including birth defects and developmental delays, the RBSK provide targeted, comprehensive care to children aged 0–18 years. It takes care of screening, early intervention, management and treatment, including surgeries for the required health conditions, free of cost[1]. A formative research study carried out in eight districts across 5 states found that 25% of the children were screened to have a Congenital Heart Disease (CHD). They received treatment with private health providers and/or support from non-profits and philanthropic institutions. The highlighted barriers reports of non-availability of facilities for diagnostics and tertiary care services[8].

Even in states such as Maharashtra, there is a reliance on diagnostic camps such as 2D Echo camps for confirming the congenital heart diseases leading to sometimes, 2-3 months waiting period for diagnosis and confirmation[8]. These results clearly suggest that universal coverage for pediatric heart care needs to be supported by public insurance schemes. Private institutions will need to partner with the government in providing for UHC in a manner quite similar to the Aarogyasrimodel[4]. The total costs for pediatric heart care will be substantial and the government has to generate the necessary resources. It is not entirely clear what the annual fund requirement will have to be. The program needs to be sustainable. In regions where there are serious deficiencies in basic maternal and child health services, substantial resource allocation for expensive heart surgery needs to be justified[8,10].

Conclusion and Recommendations

RBSK program should ensure 100% coverage. Inclusive of all AWCs as well as all schools from Government and Private sector. 100 % coverage of Rural area must be ensured with well-planned provision of Adequate budget and manpower. A robust mechanism must exist for early detection of the problems, follow up, free referral systems, prompt diagnostic mechanism, well supported treatment facilities as well as motivational counselling systems to support the health education and awareness amongst the community.

Correlation between Food and Nutrition Security and Chronic Energy Deficiency among Indian Rural Women

Zoobi Khanam

Post Doctoral Fellow, Department of Community Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Abstract

Background: Malnutrition is one of the worst problems globally and is inseparably interconnected with poverty. Under nutrition during intra-uterine and early childhood periods causes risk of frequent infections subsequent increase in maternal and child morbidity and mortality. The aim of present study was to find out the association between food and nutrition security and chronic energy deficiency in women of reproductive age group of rural India.

Material and Method: This study was conducted among 448 rural women of reproductive age group (15-49 years) in rural Varanasi using face to face interview for assessing the food and nutrition security and nutritional status. The required sample size was selected by adopting multi-stage random sampling procedure. Interview schedule contained information regarding food security, 24 hour dietary intake, body mass index and socio-demographic variables. Collected data was analysed with the help of SPSS software, version 22nd.

Results: It was observed that out of 119 high and marginally food secured subjects, 34.45%subjects were chronic energy deficient whereas 65.55%had normal body mass index. There existed significant association between nutritional status of study subjects and food security at household level ($p<0.05$). Statistically significant difference was found when carbohydrate, protein, fat and energy content were compared according to the BMI and food security categories. Socio economic class gradient also prevailed in the occurrence of chronic energy deficiency in the study subjects (<0.001).

Conclusion: It is evident from the results that there is a strong significant correlation between food and nutrition security and prevalence of chronic energy deficiency among subjects.

Keywords: *Chronic energy deficiency, food and nutrition security, reproductive age group, rural women.*

Introduction

In India, women comprised nearly 50%of the population and 1/3rd of labour force. Nearly 70 % of Indian population resides in rural areas[1] and rural women of reproductive age group (15–49 years) are at the utmost risk of malnutrition, anaemia and ill health and these are worsened by pregnancy and hard physical labour[2].

Under nutrition which is a form of malnutrition is one of the worst problems globally and is inseparably interconnected with poverty. Under nutrition can be divided into protein-energy malnutrition and micronutrient deficiencies.[3] Global hunger had affected 815 million people in 2016, or 11% of the worldwide population.[4] Maternal and child undernutrition lead to at least 3.5 million deaths each year and 11% of the total global disease burden. Current literature from developing countries shows that undernourished women with a body mass index (BMI) below 18.5 demonstrate a progressive upsurge in mortality and morbidity[5].

Undernutrition during the period of foetus development and early childhood agesresults in low

birth weight baby who is prone to frequent infections and causes increased risk of morbidity and mortality in mother and child both[6]. Hence, the main aim of present study was to find out the correlation between food and nutrition security and chronic energy deficiency in women of reproductive age in rural Varanasi. With this background following specific objectives were decided:

1. To find out the association between chronic energy deficiency (CED) among study subjects with their socio-demographic variables.
2. To observe the association between CED and food security.
3. To investigate the correlation between nutrient intake and CED.

Material and Method: Present study was conducted among rural women of reproductive age group (15-49 years) in Varanasi district of Uttar Pradesh state in India. This required a scale based in-depth interview for assessing the Food and Nutrition Security and application of indirect method of nutritional assessment. However, role of socio-demographic variables in these areas cannot be underestimated. The study was conducted in Chiraigaon Community Development (CD) Block of Varanasi district, which was selected out of 8 community development blocks by simple random sampling method. Women of reproductive age group, who were pregnant at the time of study, overweight/ obese and seriously ill were excludedfrom the study.

Study design: A community based cross sectional design was adopted for this study.

Sample size: Sample size was fixed on the basis of prevalence of CED among women of reproductive age group. As per literature search prevalence of CED in rural women of reproductive age group is 38.8%.[7] Based on this value, the sample size for this study was calculated using the formula i.e. $n=Z^2 pq/L^2$

Where: z= 1.96, n= Sample size, p= Estimated prevalence of CED (40 %), q= 100-p, L= permissible level of error is taken as 10% of the prevalence rate

The required sample size was calculated to be 576.24. Taking an additional sample of 5% for drop outs required sample size became 605.04 which were rounded to 610. Later on 162 overweight and obese subjects were excluded from the estimated sample size to make the present study more focused on CED. Hence the total sample size was fixed upto 448.

Sampling Methodology: The required sample size was selected by adopting multi-stage random sampling procedure. In the first stage, one Commisionary of Uttar Pradesh state (comprising of 7 districts) was selected randomly. Then one Community Development Block (i.e. Chiraigaon) was selected out of eight Community Development Blocks of Varanasi district by simple random sampling. In 3rd stage, 5 villages (i.e. Narayanpur, Dubkiyan, Umrahan, Tilmapur and Bariyasanpur)out of 84 revenue villages were selected by systematic random sampling. In stage 4, the required study subjects were selected adopting probability proportion to size (PPS) sampling technique and in order to get required no. of study subjects, every seventh household was selected by systemic random sampling. In the last stage one study subject was selected from each household by lottery method.

Tools & Technique of the study: The present investigation is a field survey based study in which primary tool used was a pre designed and pre-tested interview schedule for recording of information pertaining to the subjects considered for the study. The Interview Schedule comprised of following sections:

A. General information: This section contained information pertaining to socio-demographic factors i.e. religion, caste, occupation, marital status, type of family, education and socio-economic status.
B. Information regarding Food and Nutrition Security: A modified 6-item US household food security survey module[8] was used to score regarding food security in the household. The questionnaire was first tested for validity in Indian rural areas. After some modifications questions were modified in interview schedule. Present study is based on 3 point scale of this module. This section also incorporated information pertaining to dietary intake by 24 hours oral questionnaire method. Standardized utensil such as bowls, spoons were used to measure food items during diet survey. The schedule was pre-designed and pre-tested through a pilot study on 30 rural women of non study area.
C. Nutritional status: Nutritional status of study subjects was assessed by BMI. Anthropometric measurements viz. weight, height were recorded with the help of anthropometric rod and weighing machine (Libra) following standard technique. BMI

of each study subject was computed by using the formula weight (kg)/ height (m^2). Nutritional status of study subjects were graded according to proposed criteria of BMI for Asiansby WHO.[9]

Data collection: Dietary assessment of study subjects was done by using 24 hour dietary recall oral questionnaire method. Standard utensils (e.g. bowls for measuring cooked rice, dal, curd, vegetables, milk etc.; spoon for measuring oil, sugar etc.) were used for measuring the approximate intake of different food items. Dilution factor of liquid food such as dal was also noted. Diet survey was not conducted on the day after any festival or any other special occasion.

Socioeconomic Status: For monthly income of the family statements were recorded from the study subjects and confirmed from head or responsible members of the family. The social class of the subject was determined by modified BG Prasad classification (2018)[10].

Statistical analysis: Data thus generated were analysed with the help of Microsoft excel 2007 and SPSS version 22nd software. US household food security module was used to categorize level of food security in household. Intake in terms of energy, protein, fat, vitamin A, C and iron were computed as per Nutritive Value of Indian Foods.[11] Appropriate statistical tools were applied to draw relevant influences. In order to identify contribution of influencing factors, statistics incorporated in this study included χ^2 and unpaired t test.

Results

Association of CED among study subjects with their socio-demographic characteristics demonstrated the extent of CED maximum (30.6%), in the age group of 15-24 years. Corresponding value was 24.46% in 25 to 34 years age group, 24% in 35-44 years and 21.74% in ≥45 years of age group. There was significant ($p<0.001$) inversely correlation between nutritional status and age group of study subjects. CED was found significantly ($p<0.05$) more in Muslim (41.18%) than in Hindu subjects (25.60%). Maximum no. ofthe subjects belonging to joint family (32.04%)had CED. Corresponding value was significantly ($p<0.05$) lower in subjects belonging to nuclear (24.59%) and three generation (8.69%) families. Majority of subjects(34.04%) who were unmarried and 24.16% married subjects were victims of CED significantly ($p<0.001$),whereas none of the widow or subjects separated from spouse belonged to this category.

Although educational status and socio-economic status (SES) of study subjects were significantly ($p<0.001$) associated with nutritional status, there was no discernible trend. Maximum no. of subjects under category of CED had their education upto high school (31.43%) and middle school level (31.34%). There existed no significant association between nutritional status of the study subjects and occupation.

There existed significant association between nutritional status of study subjects and food security at household level ($p<0.05$) as shown in table 1. It was observed that out of 119 subjects having food security at high and marginal level,65.55%had normal BMI (18.5-22.9 kg/m2) whereas 34.45%were the victims ofCED. Corresponding value for subjects belonging to low and very low food secure households were, 26.47% and 23.37% respectively.

In current study, all nutrients i.e. carbohydrate, protein, fat, calcium, phosphorous, iron and calories were reported least among subjects with CED. Statistically significant ($p<0.05$) correlation was found when these nutrients were compared with BMI categories (table 2).

Table 1: Association of food security statuswith chronic energy deficiency among subjects.

Variables	Food Security Category						Total	
	High/Marginal Food Security		Low Food Security		Very Low Food Security			
	N	%	N	%	N	%	N	%
Nutritional Status								
CED	41	34.45	18	26.47	61	23.37	120	26.79
Normal	78	65.55	50	73.53	200	76.63	328	73.21

Discussion

Satisfactory nutrition is essential for accomplishing ideal health,quality of life and efficiency of nation. Adequate and proper nutrition can be achieved more rapidly through the continuous availability, accessibility and affordability of safe and nutritious and hygienic food to all people at all time.

In this study out of 448 subjects 41.52%, 31.03% and 22.32% subjects belonged to the age groups of 15-24 yrs, 25-34 yrs and 35-44 years, respectively. Women of younger age group (15-34 years) are more likely to be victims of under nutrition. According to Hazarika et al, in Indian context under nutrition is more in younger women 15-19 years and older ones (40-49 years),[12]this study also support the findings of present investigation. Majority (414) of them was from Hindu religion and rests (N=34) were Muslims.In present study less CED was observed in Hindu. Whereas, in other study Ramachandran et al.[13] pointed that religion does not seem to have major difference in current or future BMI status among women as those belonging to Hindu religion are only having marginally less rates of CED and vulnerability than those belonging to other religions. As much as 149 (33.26%) and 213 (47.54%) subjects were from SC/ST and other backward castes (OBC) respectively. In comparison to present study, higher representation (64.6%) of OBC was found in the study of Srivastava et al.[14] Caste exerted significant influence; SC/ST households had larger proportion of CED in findings of Hazarika et al.[12] Similar findings have also been reported from a study conducted on women of reproductive age group in Azamgarhdistrict.[15] Muslims, SC/ST and OBC are more likely to suffer from chronic under nutrition than subjects belonging to other caste category. In the current research, 54.46% and 5.13% subjects were from nuclear and 3 generation family respectively. In the study of Rao et al.[2], proportion of nuclear families was higher (63.5%) than present study.

Data of existing study confirm that, 66.52% subjects were married which is in agreement with the figures reported by NFHS-3.[7] Two third of the study subjects were literate. The female literacy rate of the country and the state are 65.46% and 59.26%, respectively.[1] The literacy level of subjects in the present study was much more than the extent of illiteracy (55%) reported by Barker et al.[6] and in study of Srivastava et al[14] percentage was 87. Bharti et al[16] also reported that under nutrition declined with increasing level of education in both rural and urban areas. In the present analysis although there is not any discernible trend between education and CED among subjects yet the lowest proportion of CED was found among subjects with highest category of education i.e. graduation and above. As observed in another study, the women educated upto high school or above are predicted to have a high BMI than one who is not. Similar to the fact of highly educated women suffer less from CED[16]. Contrary to this finding, in present study subjects who were educated up to high school were the highest victim suffering from CED. Contrary to this another study reported under nutrition more in illiterates.[12]

The occupation of the subjects was not significantly associated with nutritional status in this study. A study from Java[17] identified middle age and involvement in agriculture and domestic work as risk for CED, whereas present study demonstrates the higher prevalence of

CED among skilled workers (39.13%). The proportion of students to be victim of CED was also on higher side.

It is obvious through this study that 65.83% subjects belonging to low and very low food secure households were suffering from CED. Although there were 34.45% subjects also who belonged to high or marginally food secure households under CED category. This could possibly be due to inappropriate intra household food distribution among women.

In present study energy, carbohydrate, protein and fat content was in deficit among the subjects belonging to CED Similar to this finding another study conducted on women of reproductive age group,the extent of chronic energy deficiency was more in those groups where energy deficit was additionally of higher extent.[15] Women who were taking inadequate nutrients were more likely to be undernourished as compared to those who were taking adequate nutrients. The same result was found in studies performed in rural Kenya and Burkina Faso among women of reproductive age group[18].

Conclusion

It is obvious from the outcomes that chronic energy deficiency is higher among rural women of reproductive age particularly when paired with low food security of the household. Therefore, interventions like nutritional rehabilitation, health education regarding micro nutrient intake, continuous nutritional assessment and screening is needed. For ensuring food security and good nutritional status drafted policies need to be enhanced by targeting towards the food and nutrition security, particularly in food-insecure households as to increase their agricultural productivity,strengthen their income and empower women.

Ethical Clearance: The study had prior approval of the academic bodies of Banaras Hindu University, Varanasi and prior consent was taken from the study subjects for participation in this study.

Effect of Leg Crossing and Muscle Tensing Technique on Pain among Children Undergoing Venipuncture

Vimala Thomas[1], Rupali Salvi[2], Nisha Naik[3], Mary Ajith[3], Vaishali Jagtap[4]

[1]M.Sc. Nursing, [2]Principal, [3]Asso-Professor, [3]M.Sc. Nursing, [4]Assistant Professor, Dr D.Y. Patil University, Pimpri, Pune

Abstract

Background: Procedures that require a needle prick are among the most common procedures for pediatric patients in the health care setting and are a source of pain. Pediatric patients experiencing acute behavioral distress while undergoing routine venipuncture has been reported to range from 28% to 83% .[5]

Objectives: The objective of the study is to assess the effect of leg crossing and muscle tensing technique on pain among children undergoing venipuncture.

Materials and Method: An evaluative study with true experimental posttest only control group design used to assess the effect of leg crossing and muscle tensing technique on pain among children undergoing venipuncture; 60 samples were taken using Non-Probability Purposive Sampling Technique from selected hospital, of which 30 were control group and 30 were experimental group. The data was collected using self-structured demographic data and Wong's bakers faces pain scale.

Results: The analysis was done by using descriptive and inferential statistics. Researcher applied unpaired t test to compare pain during venipuncture among children and fishers exact test for association of level of pain with selected demographical variables. When the samples were assessed 40% of children in experimental group and in control group 63.33% of children had severe pain during venipuncture which shows that leg crossing and muscle tensing technique is found to be effective among children undergoing venipuncture. T-value was found to be -2.247 and corresponding p-value was 0.014 which is small (less than 0.05). Findings related to association of level of pain with selected demographical variables was assessed by using fishers exact test. Since the p-values are small (less than 0.05) the null hypothesis is rejected. Age in experimental group and age and education in control group are the demographical variables which was found to have significant association with level of pain. After comparing between experimental and control group level of pain, it was proven that there was decrease in pain level.

Conclusion: Pain management is an essential component of nursing care and one of the main responsibilities of pediatric nurses. Unmanaged pain could result in short- and long-term physiological, psychological, and emotional consequences. So, when performing procedures like venipuncture, concern should be to minimize discomfort and pain for children.

Introduction

Needle-related procedures (venipuncture, IV access, SC, IM) are the most important sources of pain and distress in children in hospital setting. A study shows that only 31% of children benefit from procedural pain management during the insertion of an IV access and

less than 1% during a venipuncture.[4] Even the pain killer injection needs a needle prick. The pain that accompanies procedures may induce anxiety in both pediatric and adult patients, with significant consequences. Needle phobia is estimated to affect approximately 10%–20% of the population.[2]

Relief of pain is a basic need and right of all children. Pain can be reduced with leg crossing and muscle tensing technique and this does not mean that you will ignore the pain completely and suffer in silence. It just means that you can divert your mind from pain. This allows your body and mind to be stronger and avoid the sense of pain. It will hurt if you think about it, so why not just let go and focus more on the task at hand. Do not do work which will focus on the part of the body which is aching human beings.[8]

Distraction can be used as one of the strategies to gain co-operation of the child. Non-pharmacological method are distractions which is a proven effective psychological intervention that the ability to focus attention on something other than pain and does not mean that the pain is gone.[13]

It is reported that anxiety in children can increase their subjective perception of pain, but it can be reduced if their attention is focused on a pleasant activity. [14]

The Investigator's clinical experience found that less or no interventions were done in reducing the pain among children during painful invasive procedures in hospitals. In addition, it was seen that pain can have long term consequences on children. Considering all the above-mentioned facts, the Researcher found it very essential to conduct the study that the leg crossing and muscle tensing technique reduce the pain felt by children undergoing needle-related procedures. Teaching pediatric patients to use the leg crossing and muscle tensing procedure is an easy, low cost, and low risk technique for clinicians to use during venipuncture.

Materials and Method

Study Objectives: To determine effect of leg crossing and muscle tensing technique on pain among children undergoing venipuncture

To find an association of pain with selected demographic variables

Study Design: The study used evaluative approach with true experimental posttest only control group design was used to assess the effect of leg crossing and muscle tensing technique on pain among children undergoing venipuncture. 60 samples were taken from selected hospitals,30 of which in control group and 30 samples used leg crossing and muscle tensing technique. The settings of the study are at Dr D. Y. Patil Hospital and Research Centre, Pimpri, Pune. The data was collected using self-structured questionnaires for demographic data and Wong's bakers faces pain scale.

Findings:

Section I: Description of samples according to their demographic variables in frequency and percentages.

Majority of the children 28(47%) belong to the age group of 10-12 years. Most of the children 41(68%) were females. Maximum samples 26(43%) belong to std 7th std-9th. About 45(75%) of the samples were medical cases. Above half frequency 52(87%) had history of previous experience of venipuncture. Most of the children 27(45%) had 3-4 times of previous experience of venipuncture. Majority of the children 34(57%) had undergone venipuncture for withdrawing blood.

Section II: Analysis of data to determine the level of pain among children undergoing venipuncture in experimental group.

Figure 1: Pie diagram shows description of level of pain response in children undergoing venipuncture in the experimental group.

In experimental group, majority of 40% (12) of the children undergoing venipuncture had severe and moderate pain 20 % (6) of them had mild pain and none of them had experienced no pain.

Section III: Analysis of data to determine the level of pain among children undergoing venipuncture in control group.

Figure 2: Pie diagram shows description of level of pain response in children undergoing venipuncture in the control group.

In control group, majority of 63 % (19) of the children undergoing venipuncture had severe pain,30% (9) of them had moderate pain,7% (2) had mild pain and none of them experienced pain.

Section IV: Analysis of data related to the comparison of the effect of leg crossing and muscle tensing technique on pain among children undergoing venepuncture in experimental group and control group.

Table 1: Description on the Comparison of the level of pain among children undergoing venipuncture in experimental and control group n=60

Sr.No.	Level of Pain	Mean	Mean Difference	Standard Deviation (s)	Unpaired t Test	p-value
1	Experimental group	5.966	1.067	1.95	-2.247	0.014
2	Control group	7.033		1.711		

Among children, the mean experimental group score was 5.966 and the mean control group score was 7.033 with standard deviation experimental group score was 1.95 and the standard deviation control group score was 1.711. The calculated mean difference was 1.067 and the obtained 't' value -2.247 was significant at $p<0.05$. Hence the null hypothesis was rejected. It was inferred that there is a significant difference between mean post-test levels of pain associated with venipuncture among children in experimental and control group.

Section V: Analysis of data related to association of levels of pain with selected demographic variables in experimental group and control group.

Demographic variables age found to have significant association with level of pain in experimental group and age and education in control group.

Discussion

Present study was done on 60 children who underwent venipuncture, to assess the effect of leg crossing and muscle tensing technique. The samples were divided into two groups, 30 patients using control group with no intervention and 30 patients using leg crossing and muscle tensing technique.

When the samples were assessed 40% of children in experimental group and in control group 63.33% of children had severe pain. In experimental group unpaired t test was applied to compare pain during venipuncture among children and the t-value was found to be -2.247 and corresponding p-value was 0.014 which is small (less than 0.05). Findings related to association of level of pain with selected demographical variables was assessed by using fishers exact test. Since the p-values

are small (less than 0.05), null hypothesis was rejected. After comparing between experimental and control group level of pain, it was observed that leg crossing and muscle tensing technique is effective in reducing pain among children undergoing venipuncture

Conclusion

The purpose of the present study was to assess the effect of leg crossing and muscle tensing technique on pain among children undergoing venipuncture. The overall experience of conducting this study was satisfying and was a new learning experience for the researcher. In this study since the ($p < 0.05$) H0 (null hypothesis) was rejected. It is evident that the leg crossing and muscle tensing technique is effective in reducing pain among children undergoing venipuncture. The nursing profession could pay an important role in encouraging children to adopt leg crossing and muscle tensing technique while undergoing venipuncture.

Risk Factors and Triggers of Cardiovascular Events

Shital Sharma[1], Vinay Kumari[2], Tarika Sharma[3], Bindu Joseph[4], Jyoti Sarin

[1]Vice Principal, Department of Nursing, Bharat School of Nursing, Kurukshetra, Haryana, India, [2]Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, [3]Assistant Professor, Institute of Liver and Biliary Sciences, New Delhi, India, [4]Assistant Professor, [5]Principal, M.M College of Nursing, Maharishi Markandeshwar (Deemed to be University), Ambala, Haryana, India

Abstract

Introduction: Cardiovascular events are the leading cause of mortality and disability globally. Risk factors for cardiovascular events are well established, but the factors that may precipitate the acute event are not much clear.

Aims and Objective: To identify risk factors and triggers linked to the onset of cardiovascular events.

Materials and Method: A descriptive cross sectional design was adopted for assessing the risk factors and triggers of cardiovascular events amongst patients admitted in MMIMS & R Mullana, Ambala, and Haryana. Fifty patients with cardiovascular events were interviewed using a validated interview schedule.

Results: Smoking (64%), hypertension (58%), anemia (30%), diabetes (24%), alcohol consumption (22%), overweight (16%), hypercholestremia (10%) were the most common risk factor reported by the study subjects. Unusual mental stress, Heavy physical activity within a 24 hrs prior to the onset of cardiovascular events, physical injury/Illness in last week, heavy meal consumption, sudden change in temperature were the common triggering factors identified.

Conclusion: Cardiovascular events can be prevented through refraining from risk factors and triggers by adopting lifestyle modifications.

Keywords: *Risk factors, Triggers, Cardiovascular events*

Introduction

Ischemic heart disease and stroke are the major killer diseases and accounted for 15.2 million deaths in 2016 and have been the leading causes of death worldwide in the last fifteen years.[1]

Heart attacks and strokes are typically sudden events mainly caused by atherosclerotic blockage in the coronary and cerebral blood vessels respectively. Strokes can also be caused by rupture of cerebral vasculature resulting in intracranial haemorrhage.[2] Stroke is not only the leading cause of death globally but also one of the principal causes of disabilities in adults. The incidence of stroke has increased over time in certain countries.[3] Despite advancements in diagnosis and management over years, cardiovascular events tend to be a major public health problem.

Risk factors for Stroke and Myocardial Infarction are known, but there is less known about factors surrounding the acute event. Established risk factors for heart attacks and stroke can only partially tell the individual risk and do not foresee the timing and day of the acute event. Identification of patients with controllable risk factors is imperative and the avoidance of probable triggers

amongst them can be very helpful in prevention of onset of cardiovascular events.

Methodology

A descriptive research design was used to ascertain the risk factors and triggers of cardiovascular events amongst fifty conscious patients admitted in MMIMS & R hospital, Mullana, Ambala, Haryana. Ethical permission was obtained from Institutional Ethical Committee [IEC-961].

The adult patients oriented to time, place and person were interviewed for collecting data regarding Sample Characteristics, Risk Factors, and Triggers using a Structured Interview Schedule within 24 hours of admission. In case, patient was not able to recall in between, help of relatives/witness was sought. The time taken to collect the data from each patient varied from 15-20 minutes.

Structured Interview Schedule developed by the researcher was used and had four sections. Section 1 & 2 comprised of demographic and clinical variables respectively. Section 3 & 4 had questions pertaining to risk factors and triggers related to onset of cardiovascular event respectively.

Risk factors included history of previous cardiovascular events, family history of cardiovascular events, history of hypertension, history of diabetes, hypercholestremia, anemia, smoking, tobacco chewing, alcohol intake. The triggers included time of onset of cardiovascular event, position, activity, smoking 2 hours before the onset of cardiovascular events, drinking 2hrs prior to occurrence of cardiovascular events, physical injury/illness within a week, faced unusual events within a month, heavy meal consumption within 24 hrs prior to onset.

The content validity of the tool was ascertained through seven experts from medical and nursing field. Content validity index (ICVI) of risk assessment sheet varied from 0.75-1 and overall content validity index (SCVI) was 0.87. Content validity index of triggers assessment sheet ranged from 0.75-1 and scale content validity index (SCVI) was 0.89. Reliability of tool was calculated by test retest method (r=.804).

Statistical Analysis: SPSS version 20 was employed to analyse the data. Data analysis was done by using descriptive and inferential statistics i.e frequency percentage and chi-square test. For the present study, the level of significance was $p \leq 0.05$.

Result

Sample Characteristics: Majority of the patients (64%) were more than 50 years of age; 36% in the age group of 35-50 years. Most (66%) of patients were male. Majority (82%) of patients was Hindu and 16% were Muslim and only 2% were Sikh. Most (64%) of patients were vegetarian. Nearly half (46%) of patients were non-literate. About 38% were employed, 32% were housewives, 22% were retired, 4% were farmer and 4% were labourer. All the patients were married. Majority (80%) of the patients belonged to middle/lower middle socio-economic status and lived in rural areas. Most (62%) of the patients were living in nuclear family.

Clinical Parameters: More than half of the patients (54%) had myocardial infarction whereas 46% of the patients had stroke. Ischemic stroke patients (91%) outnumbered the hemorrhagic stroke patients (9%). Nearly 58% of the patients were overweight and obese. Most (70%) had normal Hb followed by 30% of patients had low Hb.

Prevalence of Known Risk Factors: About 24% of patients reported prior history of stroke or myocardial infarction and majority (83.3%) of them had history within one month. Family history of stroke or myocardial infarction was reported by only 3 patients.

More than half i.e 29/50patients (58%) had history of hypertension; nearly 50% were diagnosed within a year and regular intake of antihypertensive drugs was reported by only 17 out of 29 hypertensive patients. One fourth of the patients (24%) had history of Type 2 Diabetes Mellitus; 50% were diagnosed within a year only; majorities (11/12) were complaint to the treatment. About 10% of the patients had history of hypercholestremia. None of the female patients had any history of intake of birth control pills. More than half ie 32/50 (64%) had history of smoking; 23/32 (72%) were current smokers and had been smoking more than 20 years and 11/23 current smokers used to smoke more than 15 cigarettes per day. Four out of fifty patients had history of chewing tobacco.

About 22% patients (11/50) had history of drinking alcohol; 07 were current alcoholics with duration of alcoholism more than 10 years. And more than half (57.1%) of the current alcoholics had binge drinking

occasionally. None of patients were currently taking any illicit drug.

Potential Triggers Related to Onset of Cardiovascular events: One third (34%) of patients had cardiovascular event between 6am-11:59am; 22% patients had event in each of the remaining 6 hours time period. Thirty one percent of patients were in sitting position, 26% were sleeping/just awakened and 26% were lying, 8% were defecating/urinating, 6% were in standing position, one patient was busy in farming and other was climbing stairs before the occurrence of cardiovascular event. Most common posture in which cardiovascular events occurred was supine (46%), sitting (30%), squatting (12%) and standing position (12%). About one fourth (24%) of patients smoked 2 hours prior to onset of cardiovascular events and majority (83.3%) of them smoked 4-6 cigarettes. Only one of the patients consumed alcohol 2 hours prior to onset of cardiovascular events and had 2-4 pegs of alcohol. About 26% had physical injury or infection 1 week before the onset of cardiovascular event; 11 patients had fever and two had fracture. One third (34%) had taken some medicine 02 hrs prior onset of cardiovascular events; 12 reported intake of over the counter and 05 had taken prescribed medicines. Six patients (12%) had consumed heavy meal within 24 hours before the onset of cardiovascular event.

Nine patients faced unusual event in the last 24 hrs of onset of stroke; heavy physical activity(4), death in family (03), violent quarrel (02). About 11 (22%) patients were under unusual mental stress within a month prior to onset of cardiovascular events.

A significant association of smoking in 2hrs before the onset of cardiovascular event was seen with type of cardiovascular event, history of diabetes mellitus, anemia. 37% of patients with myocardial infarction had history of smoking 2hrs prior to onset of cardiovascular events as compared to 8.7% of patients with stroke (x^2=5.73; p=0.01). 31.6% of non-diabetic patients had smoked 2hrs prior to onset of cardiovascular events as compared to none of diabetic patients(x^2=4.98, p=0.02). 24% of Non-anemic patients had smoked 2 hrs prior the onset of cardiovascular events as compared to none of anemic patients (x^2=3.94; p= 0.04).

Discussion

In the study, there was one peak timing for the occurrence of stroke. In 34 % of the subjects, peak was between 6.00-11.59 a.m. Chakrabarti et al. found 52% of strokes among Indians occurred between 5-9 am.[4] Vinay et al reported two peak timings for stroke occurrence i.e 5am-9:59am (27.9%) and 3pm-7:59pm (25%). Increase in morning blood pressure[5], aggregability of platelets, blood viscosity and haematocrit may be considered as a causative factor for peak occurrence of cardiovascular events in morning.[6,7]

About one fourth (24%) of patients smoked 2 hours prior to onset of cardiovascular events and majority (83.3%) of them smoked 4-6 cigarettes. 37% of patients with myocardial infarction had history of smoking 2hrs prior to onset of cardiovascular events as compared to 8.7% of patients with stroke (x^2=5.73; p=0.01). 31.6% of non-diabetic patients had smoked 2hrs prior to onset of cardiovascular events as compared to none of diabetic patients (x^2=4.98, p=0.02). 24% of Non-anemic patients had smoked 2 hrs prior the onset of cardiovascular events as compared to none of anemic patients (x^2=3.94; p=0.04). Smoking bans are related with a rapid decline in the incidences of acute myocardial infarction pointing that cigarette smoking is an avertable precipitator of MI.[8] The risk of acute cardiovascular events is higher in the presence of risk factors like smoking, high blood pressure, high cholesterol levels, diabetes or the presence of cardiovascular disease.[9]

About 26% had physical injury/infection 1 week before the onset of cardiovascular event; 11 patients had fever and two had fracture. A Study supports that recent respiratory symptoms are linked with higher risk of Myocardial Infarction in 1–2 weeks[10] and influenza triggers cardiovascular events.[11]

Nine patients faced unusual event in the last 24 hrs of onset of stroke; heavy physical activity (4), death in family (03), violent quarrel (02). The chances of MI were 5.9 times more (95% CI 4.6–7.7) within one hour of heavy physical work in comparison to periods of lower levels of activity/rest.[12] A case-crossover study on ischemic stroke found an association with anger in the two hours preceding symptoms and also exposure to negative emotions during the hazard period was associated with a high odds ratio for ischemic stroke.[13]

About 11(22%) patients were under mental stress within a month prior to onset of cardiovascular events. In another study, 31.4 % of the subjects reported experience of some extraordinary/unusual event within 24 hours prior to the onset of stroke and unusual mental

stress was the most common unusual event reported by majority (65.9 %) of them.[14]

Six patients (12%) had consumed heavy meal within 24 hours before the onset of cardiovascular event. The relative risk of an acute cardiovascular event in the first hour after intake of heavy meals was seven times higher than the comparable hours on the previous day and four times more than estimated based on the usual frequency of heavy meal intake in the last year.[15]

The findings of the present study suggest that unusual mental stress, Heavy physical activity time of the day, injury/illness within a week prior to the occurrence of stroke, smoking among diabetes may lead to the onset of cardiovascular events. These events can be prevented through modification in life style (refraining from triggers), compliance to treatment and regular follow up.

The study has potential sources of biases which may limit the generalization of findings. The sample size was only fifty and taken through convenience sampling technique. Moreover, the data collection was limited to conscious patients only and collected through self report technique only which may introduce reporting and recall biases. Lack of control group also limits the confidence in the study findings.

Case control studies or case crossover can be undertaken on larger sample for identification of triggering factors related to onset of cardiovascular events.

Nurses have an important role in raising awareness regarding prevention of cardiovascular events and to motivate people at risk to adopt lifestyle modifications. Knowledge of the risk factors and the triggering factors related to cardiovascular events is imperative for the nurses. People having cardiovascular risk factors must be identified and educated about triggering factors.

Passive Smoking and its Effects on the Development of a Child

Deveshi Gupta[1], Arathi Rao[2], Suprabha B.S.[3]

[1]Post Graduate Student, [2]Professor, [3]Professor and Head of the Department, Department of Pediatric and Preventive Dentistry, Manipal College of Dental Sciences,, Light House Hill Road, Mangalore-575001, Manipal Academy of Higher Education (MAHE)

Abstract

Passive smoking is the inhalation of the tobacco smoke of another individual or the exhale of a smoker. There is no safe level of second- hand tobacco smoke exposure. This review article delves into the consequences of passive smoking on the physical, cognitive development, and the circulatory system of the child. Nicotine exposure increases the oxidative stress of the body, while decreasing the antioxidant capacity. It transiently increases the systolic blood pressure and decreases the arterial compliance, thereby increasing the susceptibility to hypertension.

Exposure to tobacco smoke delays the dental development amongst children and displays a negative association in the linear growth of the child. It also increases the risk of dental caries and behavioural problems.

Keywords: *Passive Smoking, Cognitive, Circulatory System, Physical Development, Dental caries*

Introduction

Smoking can be defined as the inhalation of the burning tobacco smoke encased in cigarettes, pipes and cigars.(1) Passive smoking (PS) is the inhalation of tobacco smoke of another individual or the exhale of a smoker.(1)

According to the World Health Organization, out of the 8 million people who die globally due to tobacco use, 1.2 million are passive smokers.(1) There are more than 7000 chemicals in tobacco smoke, out of which at least 250 are proven to be harmful and 69 are carcinogenic.(1) Unfortunately, there is no safe level of exposure to second-hand tobacco smoke.(1)

The developing foetuses suffer greatly from the chemicals present in the smoke as they have a reduced nicotine detoxification capacity.(2) Similarly, children are more sensitive to the smoke as they have a greater Alveolar Ventilation to Perfusion ratio, with the added disadvantage of underdeveloped lungs.(3)

The present article describes the consequences of passive smoking and its effects on the physical development, circulatory system and cognitive development.(1)

Circulatory System: The circulatory system is very vulnerable to the effects of passive smoking. Exposure to PS elevates the blood pressure for a small-time frame. This transient rise can be attributed to several sequential biological effects such as vasoconstriction, capillary endothelial dysfunction, and decreased nitric oxide production.(4) The impairment of endothelial function can be due to the conversion of Acetylcholine-induced coronary artery relaxation into vasoconstriction.(5) Nicotine being an adrenergic agonist, induces the release of local and systemic

catecholamines at the neuroeffector junction.[6] Thus, the vasoconstriction caused by nicotine coupled with the antagonist action of acetylcholine causes a transient rise in the blood pressure. Oxygen free radicals present within the cigarette smoke cause the muscular arteries to contract, decreasing their elasticity and compliance and thereby increasing the blood pressure.[5,7] Due to the sustained oxidative stress, smokers are also more susceptible to oxygen free radicals (Superoxide anions, hydrogen peroxides).[7] This subsequently increases the blood pressure of an individual. A meta-analysis conducted in 2019, concluded that the foetuses, and children subjected to passive smoking had a higher level of Systolic blood pressure.[8] No association, however, was drawn between hypertension and second-hand smoking (SHS). As smoking has cumulative effects, the duration of exposure would be an influential factor in determining the prevalence of hypertension in the children.[8]

There is no conclusive data, regarding the effects of cigarette smoke (CS) on the blood cells of the body. [9]According to Mahassni et al, smokers have a significantly higher mean lymphocytic count and CD4+/CD8+ ratio compared to PS. But they demonstrate lower mean IgA, basophilic and NK cell counts. Hence, first-hand smokers have an increased susceptibility to upper respiratory tract infections, while the passive smokers are more prone to hypersensitivity reactions.[9]

Thus, exposure to nicotine results in the reduction of the compliance and elasticity of the blood vessels.[5,7] This, coupled with vasoconstriction induces a transient rise in the systolic blood pressure.[5-7] Therefore, repeated exposure to nicotine, is considered the prime cause for hypertension amongst passive smokers. Smokers also have a significantly higher mean cotinine level, lymphocytic count, and CD4+/CD8+ ratio. Passive smokers demonstrate a greater mean IgA concentration, basophilic and NK cell percentage.[9,10] Nicotine promotes oxidative stress and endothelial dysfunction.[9,10]

Physical and Dental Development: Studies have shown that a dose-response relationship exists between maternal smoking during pregnancy and the linear growth restriction in children.[11,12] Kawakita et al, demonstrated that nicotine caused a decrease in the matrix synthesis and suppressed the hypertrophic differentiation of the cartilaginous tissue, thereby delaying skeletal growth in lab rats.[12] Berlanga et al and Gigante et al also, documented a negative correlation between the cotinine levels and the height of an individual.[11,13] Exposure to smoke has contrary effects on different parts of the body. Chronic hypoxia can cause greater growth of the upper body in the early gestation period, such as head dimensions, upper limb length, and abdominal circumference. At the same time, it results in a selective decrease in biparietal head dimensions, distal limb length and abdominal diameter.[14] In a similar research conducted by Koziel et al, PS resulted in dolichocephaly amongst 7-9 year old boys. This further proved the positive association between hypoxia caused due to placental insufficiency and SHS.[15]

Disturbances in odontogenesis are affected by various factors such as: Diseases, smoking, chemotherapy etc. If the teeth are exposed at any phase prior to mineralization, it can lead to delayed development. [11] This data was in tandem with a research conducted by Dong et al where-in they noticed a delay in the mineralization and total crown formation amongst the study group (nicotine exposed). [16]In yet another study, done by Heikkinen et al in 1994, he stated that the overall size of the primary molars and canines were 2-3% smaller amongst the children born to smoking mothers. It was also noticed that this variation in size differed with race and gender. [17] Subsequently, Avsar et al, found a positive co-relation between the extent of nicotine exposure and the delay in dental development, by evaluating the plasma cotinine levels.[18] Similarly, Kieser et al., noticed that the maximum differences between chronological and dental ages were found amongst the children subjected to cigarette smoke from both parents.[19]

Dental Caries: Numerous studies point towards a positive association between SHS and dental caries.[20-24] In smokers (active and passive), there is a decrease in the salivary buffering capacity, and an increase in the lactobacilli and *S. mutans* count.[20] Literature states that nicotine not only enhances the S. mutans biofilm formation and metabolic activity, but it also increases the extracellular polysaccharides. This further attracts other microorganisms, such as Candida albicans, onto the dental plaque.[20] Bernabé et al, in the year 2017 proved a steeper incidence of caries amongst low birth-weight children and maternal smokers.[21] This was further proved by Tanaka et al, where-in there was a significant increase in the incidence of dental caries amongst those children whose mothers smoked during the first trimester of their pregnancy.[22,23]

The ramifications that exposure to tobacco smoke has, on the physical and dental development of children goes beyond just the foetal development. Nicotine instigates, chronic hypoxia due to placental insufficiency, resulting in altered body proportions and head dimensions.[11-15] Further, it has been proven that passive smokers have a delayed dental development and an increased risk of dental caries as compared to non-smokers.[20-23]

Cognitive Development, behaviour and Motor Skills of the Child: The results from various studies pertaining to the cognitive development of children, following tobacco smoke exposure (TSE) is controversial and inconclusive. Most of the authors believe that foetal hypoxia impairs brain development. [24] A study done by Slotkin et al, on rats, proved that various environmental agents that encourage cholinergic activity in target cells cause neurodevelopmental damage, due to the inappropriate timing and/or intensity of the stimulation. The overstimulation of cholinergic receptors resulted in the excessive expression of genes, that promote apoptosis and delayed cell loss. Exposure to second-hand smoke also causes an impairment in the Acetyl choline (reduced HC3/ChAT ratio) and 5HT presynaptic activity.[25]

Slotkin et al in 2016 focused on the importance of a "critical period" for the development of adverse effects of TSE.[26] They observed that during the early exposure to the toxin, the neurons that have been lost can be replaced due to the plasticity of the neuronal cell replication. Hence, the massive initial disruption of the brain up to stage of the neural tube development can be repaired and a near normal morphology obtained. Contrary to this, the late gestational phase (third trimester of human development) comprises of terminal neurodifferentiation and the assembly of higher-order brain structures- stages that, if interrupted, are not easily reversible.[26] This was further proved by Eskenazi et al, where in they observed that the cognitive development of the 5-year olds exposed to prenatal tobacco smoke was not negatively affected. However, the development of children exposed to cigarette smoke postnatally was much poorer.[27]

Behavioural problems are seen early in the child's life; new-borns exposed to PS in-utero have a heightened startle response, tremors, hypertonicity.[28] They cry more easily and are fussier. They also react more severely to bowel movement and diapering. By around 2 years of age, these same children start to show signs of increased externalizing behaviours like defiance and inability to pay attention.[28] During the pre-school years, the most common problems encountered amongst these children include demanding attention, mood swings, emotional instability, arguing, aggression and destructive behaviour.[28] This behaviour usually continues into adolescence and adulthood, and these people are more likely to break rules or display aggression.[28]

According to Braun et al, the chances of Attention Deficit Hyperactivity Disorder (ADHD) when associated with lead and tobacco exposure are 4.1 and 2.5 times greater respectively.[29] Becker et al, noticed that the children with the DAT1440 allele or DRD47 repeat-allele were 1.8 - 2.1 times more likely to be diagnosed with ADHD. [30]Also, the children with prenatal tobacco smoke exposure along with one or both of the above-mentioned alleles were 3-9 times more likely to have ADHD.[30]

Multiple studies have been conducted to assess the correlation between motor skills (fine/gross) and tobacco smoke exposure. [31, 32] Trasti et al, observed that 5-year-old children who were exposed to tobacco smoke in-utero, had a delayed motor development.[31] In yet another study done by Yeramaneni et al, it was noticed that children (7-9years) exposed to passive smoking displayed a decrease in the fine motor integration, manual dexterity, balance, and strength. [32]

The exposure to tobacco smoke prenatally and during post-natal development can cause subtle changes in the neurodevelopment, behaviour and neuromotor function in children.[24-32] However, due to the difficulty in isolating the various confounding factors, concrete evidence has not yet been obtained.[24] It has been observed that SHS exposures cause developmental disruption that range from cell loss to specific changes in the neural activity and incorrect programming of receptor signalling mechanisms. It was also noted that these children, who were exposed to PS had had a decreased level of manual dexterity and fine motor skills.[32, 33]

Conclusion

It has been proven time and again, that passive smoking has a detrimental effect on the human body. Nicotine exposure increases the oxidative stress of the body, while decreasing the antioxidant capacity. It transiently increases the systolic blood pressure of the

body and decreases the arterial compliance, increasing the susceptibility to hypertension.

Tobacco Smoke exposure also delays the dental development amongst children and displays a negative role in the linear growth of the child. It also increases the risk of caries and behavioural problems.

Pattern and Convergence in Access to Individual Household Latrine Facility in Indian States and the Impact of Swachh Bharat Intervention

Prasant Kumar Panda[1], Pavithra S.[2], Anjali Elsa Skariah[3]

[1]Associate Professor and Head, Department of Economics, Central University of Tamil Nadu, Thiruvarur, [2]Integrated Master Scholar, Department of Economics, Central University of Tamil Nadu, [3]Research Assistant, ICSSR Funded Research Project, Department of Economics, Central University of Tamil Nadu

Abstract

Backgorund: Access to improved sanitation facility for all is an essential to maintain good health and well- being. However in India,millions of peoplesuffer from diseases and infections due to lack of adequate sanitation. Realising the importance of sanitation and hygiene, Government of India announced the flagship programme Swachh Bharat Mission (SBM) in 2014. One of the important features of SBM is to provide financial assistance to construct individual household latrine facility. It is important to understand the impact of SBMon pattern and access of households to latrine facility in Indian states.

Objective: This paper tries to examine the pattern and trends in access to individual household latrine facility from an inter-state perspective and convergencein access to latrine facility among the states after the implementation of SBM.

Method: Data have been obtained from Census, reports from Ministry of Drinking Water and Sanitation, GOI and Swachh Bharat Mission Gramin website for the period 2011 to 2018. Sigma and beta convergence techniques have been employed to analyse the convergence in access to toilet facility and percent and ratios are employed to analyse the pattern.

Results: The findings of the study confirmed the positive impact of SBM in increasing the access to toilet facility in rural India and convergence in access to toilet facility among Indian states in post SBM implementation. During the period 2014-2018, ie, after implementation of SBM, the increase in sanitation coverage at national level is four times higher than the progress made during the decade of 2001 to 2011. Many of the States have reported 100 percent open defection free Villages in the year 2018. So Implementation of SBM not only improves the share of households having latrine facility, but it has widely reduced the gap between high and low income states in access to the sanitation facility.

Introduction

Access to safe water, improved sanitation along with good hygiene is of paramount importance because of their implication on people's health and socio-economic development. Lack of access to improved sanitation is one of the main reasons for the existing disease burden in the form of diarrhoeal diseases, undernourishment, other infections and tropical diseases. The cost of poor sanitation is often measured

Associate Professor and Head, Department of Economics, Central University of Tamil Nadu, Thiruvarur
e-mail: prasantkumar@cutn.ac.in

in economic terms as the direct cost associated with the treatment of diseases related with poor sanitation, but loss of income, productivity and loss of work hours due to distant and inadequate sanitation facility also have severe implications. Considerable improvement in all of these factors can reduce mortality rates, morbidity and improve quality of life of people, especially infants and children in developing countries. Hence, water and sanitation remain the fundamental requirement of human beings.

Open defecation is the main challenge for healthy hygiene and sanitation. One of the main reasons for open defection is lack of adequate and proper sanitation infrastructure like individual household toilet facility. Globally, 2.3 billion people lack basic sanitation facilities, 892 million practice open defecation; and nearly 80% of the people residing in rural India lack improved sanitation facilities [(1)]. Over the past few years, countries have made commendable progress in sanitation facilities but the benefits are not evenly spread. It is observed in several studies that, there exists inequality between rural- urban, rich- poor, educated-uneducated, and men-women [(2-3)]. Most developing countries, including India, have excessive pressure on infrastructure facilities that is required to meet the "healthy living needs" of growing population. The challenge to provide sanitation facilities to people in the rural areas, as well as, urban areas are aggravated by rapid urbanisation and dwindling social sector investments [(4)], with millions of people falling in short of basic facilities.

Despite the staggering figures, continuous efforts are being made by the Government of India (GOI)to effectively address the problem of sanitation and water. In 1980's, GOI introduced Central Rural Sanitation Programme (CRSP), with focus on rural sanitation. The survey on drinking water, sanitation and hygiene carried out by National Sample Survey Organisation in 1998 and a similar report by Central Bureau of Health Intelligence in 1998-99, revealed shocking disparities across people living in rural and urban areas. Total Sanitation campaign (TSC) was introduced in 1999 as a restructure to existing programme, i.e, CRSP, to curtail the widening gap and worsening situation of sanitation, water and hygiene in rural India. Later in 2012, TSC was renamed as Nirmal Bharat Abhiyan and subsequently, in 2014,it was relaunched as Swachh Bharat Mission. The mission is aimed to fulfil universal coverage and to bring about a change in perception and attitude towards use of latrines, thereby, translating into use of the facilities.

In Indian context in spite of many initiatives by the government, people lack basic facilities like toilet at home. This is the basic requirement and first step towards checking open defecation and improved sanitation, though change in behaviour in adopting the use of toilet is also important. Findings from different studies show that unavailability and lack of facilities are the reasons for open defecation in India.[(5)]Also, functioning toilets[(6)], electricity facility, proximity and in- house water connections[(7)] can affect the effective and persistent use of latrine among members of household. Therefore, creation of toilet facility is definitely the first step coupled with complementary facilities (like electricity, availability of water, proper drainage etc.) will reduce open defecation.

Studies pertaining to analysis of sanitation facilities are usually at household levels. In literature many studies have tried to identify the important determinants that affect sanitation facilities of households. A study conducted in Ghana revealed that, economically active people are more likely to afford the facility.[(8)] There is prevalence of deplorable sanitation conditions of labourers in textile firms.[(9)] A study highlights uneven progress of sanitation in India.[(10)] Studies acknowledge a positive relation with the sanitary facility and wealth.[(8)] It is suggested to increase share of health spending as per cent of state GDP in the states for better health indicators.[(11)] Similarly a study observes that health is not luxury in Indian context as income elasticity of public health expenditure is less than unit.[(12)]

Even with access to latrine facility open defecation is still rampant in different parts of the country.[(2)] It is observe from a study that latrine access doesn't not always result in use of the facility.[(13)] Poor governance and lack of appropriate spending and on other side traditional practices and cultural factors influence health outcomes in India.[(14)]

There have been very limited studies in regard to analysis of the pattern of sanitation coverage, and convergence at state level in India. Besides it is important to observe the influence of Swachh Bharat Mission on increasing pattern of access to sanitation and convergence across states. In this paper we have confined our analysis to access to individual household toilets in Indian states from a macro perspective. The main objectives of the paper are (i) to analyse the level of infrastructure facility like households having individual toilets from an interstate perspective; (ii) to examine

the convergence or divergence in access to household toilet in Indian states and (iii) to verify the impact of SBM on increasing access to household toilets and on convergence across states. Rest of the paper is structured with the following sections: data and methodology, empirical results and discussion and conclusion.

Data and Methodology

Data: The data pertaining to sanitation coverage have been obtained from Census 2001 and 2011. Sanitation coverage data for 2014-2018 have been obtained from Ministry of drinking water and sanitation, Government of India. The criteria used in Census for sanitation coverage is "Availability of latrine facility within household premises". The data for the same have been taken from Swachh Survekshan conducted by Ministry of Drinking Water and Sanitation (GOI) under SBM. As the nature and pattern of resource generating financial development activities are different for special category states (SCS) than the same in general category states (GCS), we have separately analysed SCS and GCS.

Our findings reported in this paper are observed on the basis of data provided by SBM through Swachh Sarvekshan. So findings are subject to the limitation of data reported in these Swachh Sarvekshan.

Methodology: The data has been analysed using percentage – ratio method. Sigma and beta convergence tools have been employed to understand the convergence or divergence among states. For convergence, log linear trend growth rate of households having latrine has been computed by using the following regression equation:-

$$\ln(Y) = \alpha + \beta t + e$$

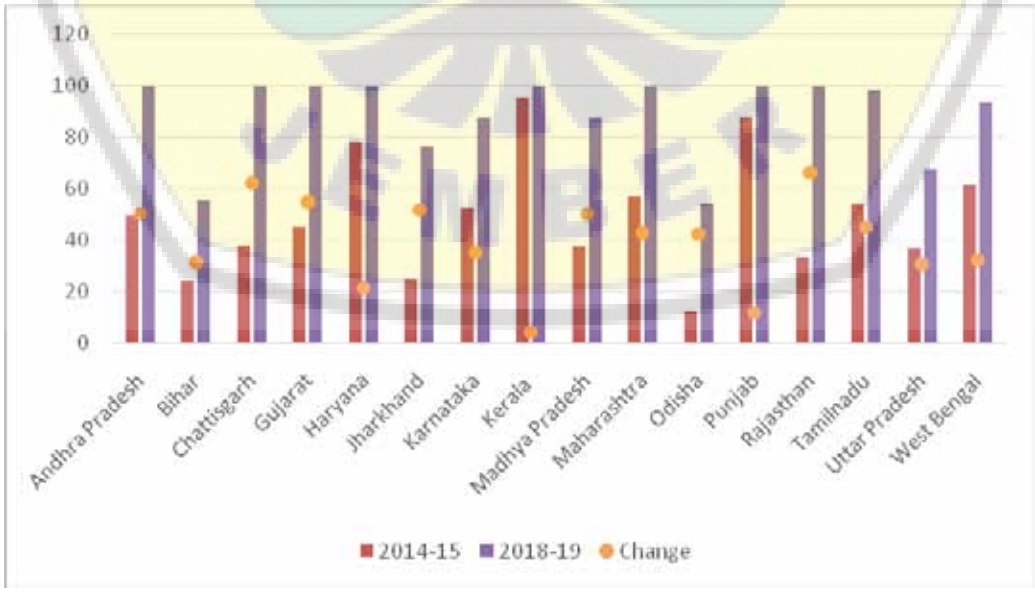
Where Y is the share of households having individual latrine;

The estimated value of β is regressed on initial level of share of households having latrine facility to find the convergence.

Empirical Results and Discussion

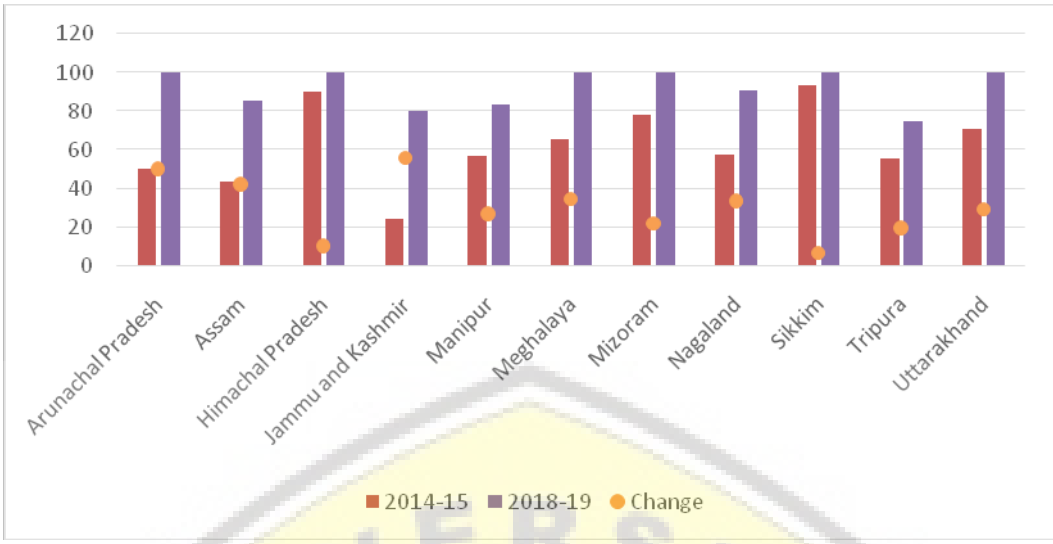
This section provides findings of the study.

Patterns and trends of sanitation coverage: The figure -1shows the change in sanitation coverage, i.e, share of households having latrines for 2014 and 2018 for the major states of India. Overall, there has been an improvement in the coverage for all major states over the span of four years. States like Andhra Pradesh, Chhattisgarh, Gujarat, Haryana, Kerala, Maharashtra, Punjab, Rajasthan, and Tamil Nadu, have reported 100% coverage in 2018. Rajasthan, Gujarat, Andhra Pradesh and Chhattisgarh have shown significant progress with an increase in coverage of more than a half, while Bihar, Odisha and Uttar Pradesh are stilllagging behind.



Source: Authors compilation from SBM data

Figure 1: Sanitation coverage for major states in India



Source: Authors Compilation from SBM data.

Figure 2: Sanitation coverage among the Special Category states in India

The figure 2 shows the sanitation coverage among the special category states for 2014-15 and 2018-19. Six out of the 11 states have attained 100% sanitation coverage in 2018-19. A similar trend of improved sanitation coverage can be observed for the special category states. States of Jammu Kashmir, Assam, and Arunachal Pradesh have made marking difference in sanitation coverage. Tripura is the only state which is has coverage share less than 80% in 2018.

Table 1: Percentage Change in Sanitation Coverage

	2014	2018	% Change	2001	2011	% Change
India	42.56	83.71	41.15	36.40	46.90	10.50
Major States	49.71	88.82	39.11	35.43	47.05	11.63
Special category states	62.55	92.16	29.61	62.75	73.35	10.60

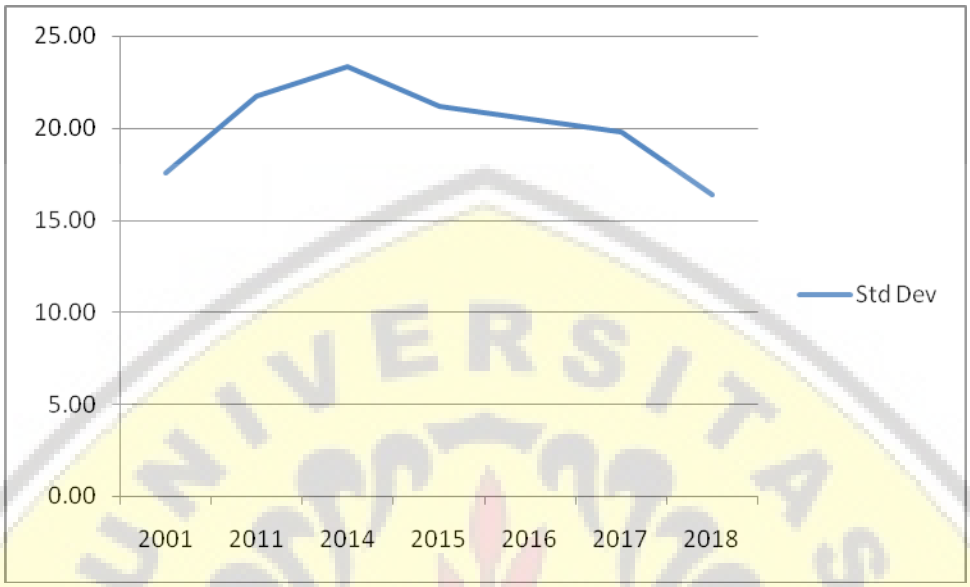
Source: Authors compilation from Census and SBM data

The table 1 shows the percentage of change in share of households having latrine facility in 2018 over 2014, and between 2001 and 2011. It is quite interesting to note the progress made in the past 4 years compared to past 10 years. During the period 2014-2018, the increase in sanitation coverage at national level is 4 times the progress made in previous decade. A striking similar trend can observed for major states and special category states. The whopping increase could be attributed to the implementation of Swachh Bharat Mission.

Convergence of sanitation facilities in Major States: Individual household latrine facility and its coverage are important for states irrespective of their income status. If the growth in the share in access to toilet facility among the deficient states can grow at faster rate than the states where majority of households have access to toilet, then convergence in access to toilet facility across Indian states will be achieved. So a larger intervention is required through policy for low income states or sanitation deficient states in order to improve their sanitation facility to converge them with high income states. So it is important to analyse how SBM has helped in converging the access to toilet facility in Indian states.

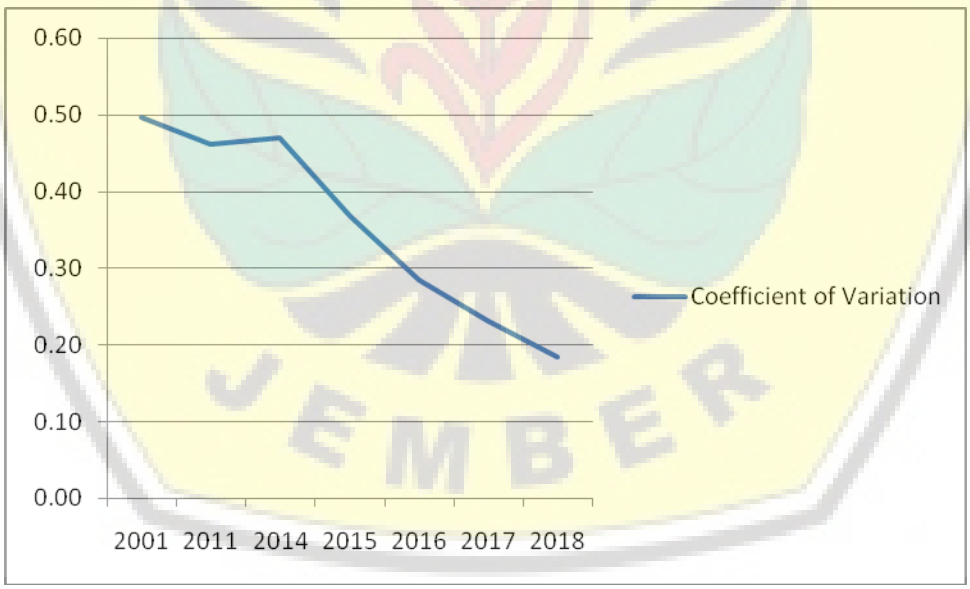
The figure-3 shows the pattern of convergence or divergence of states in coverage of individual household latrine facilities. It has been observed that the in the initial years, there is divergence among states until

2014. But after 2014, there is steady decline in standard deviation of states of sanitation coverage across states, indicating convergence of major states. The figure 4 below also depicts a similar trend and establishes that the states converge with the high performance states in due course of time.



Source: Authors calculations based on Census and SBM data

Figure 3: Pattern of convergence across states.



Source: Authors calculation based on data from Census and SBM

Figure 4: Coefficient of variation in Access to toilet facility among Indian states during 2001 to 2018

From the table-2, it's observed that the beta convergence coefficient is significant and negative for all three cases, i.e, major states, special states category and the all states taken together. Comparing years of implementation of SBM, i.e, 2014 to the current year 2018, there is convergence to access to individual household latrine facility. This suggests that the implementation of SBM not only help to improve

percentage of people having toilets but it has widely reduced the gap between low and high income states. Low income states have constructed the toilets at a faster rate to achieve the convergence with the higher income states.

Table 2: β-Convergence coefficient for Indian States

	Major States	Special Category States	Combined
b	-3.25**	-4.20*	-0.83*
	(-2.95)	(-4.79)	(-5.80)
Constant	83.49	95.48	59.24
	(-6.7)	(12.33)	(10.02)
R^2	0.42	0.72	0.59
F	8.71	22.95	33.63
	(0.01)	(0.00)	(0.00)
N	14	11	25

Note: ** indicates significant at 5% and * indicate significant at 1%., **Source:** Authors calculations based on data from Census and SBM

Conclusion

The paper is an attempt to look into the pattern and trends of sanitation facilities at state level, to understand the convergence or divergence over the years after the implementation of SBM. Indeed, the country has made striding progress in the years after the implementation of SBM. Our findings also suggest that the poor performing states in terms of facilities, are catching up with the well-off states, as well as, this progress is taking place at a faster pace. There is convergence in access to individual household latrine facility across India states after implementation of SBM. So implementation of SBM helps in improving the share of households having toilet facility in Indian states and it also widely reduces the gap in the same between high and low income sates.

Risk Factors and Triggers of Cardiovascular Events

Shital Sharma[1], Vinay Kumari[2], Tarika Sharma[3], Bindu Joseph[4], Jyoti Sarin[5]

[1]Vice Principal, Department of Nursing, Bharat School of Nursing, Kurukshetra, Haryana, India, [2]Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, [3]Assistant Professor, Institute of Liver and Biliary Sciences, New Delhi, India, [4]Assistant Professor, M.M College of Nursing, Maharishi Markandeshwar (Deemed to be University), Ambala, Haryana, India, [5]Principal, M.M College of Nursing, Maharishi Markandeshwar (Deemed to be University), Ambala, Haryana, India

Abstract

Introduction: Cardiovascular events are the leading cause of mortality and disability globally. Risk factors for cardiovascular events are well established, but the factors that may precipitate the acute event are not much clear.

Aims and Objective: To identify risk factors and triggers linked to the onset of cardiovascular events.

Materials and Method A descriptive cross sectional design was adopted for assessing the risk factors and triggers of cardiovascular events amongst patients admitted in MMIMS & R Mullana, Ambala, and Haryana. Fifty patients with cardiovascular events were interviewed using a validated interview schedule.

Result: Smoking (64%), hypertension (58%), anemia (30%), diabetes (24%), alcohol consumption (22%), overweight (16%), hypercholestremia (10%) were the most common risk factor reported by the study subjects. Unusual mental stress, Heavy physical activity within a 24 hrs prior to the onset of cardiovascular events, physical injury/ Illness in last week, heavy meal consumption, sudden change in temperature were the common triggering factors identified.

Conclusion: Cardiovascular events can be prevented through refraining from risk factors and triggers by adopting lifestyle modifications.

Keywords: *Risk factors, Triggers, Cardiovascular events.*

Introduction

Ischemic heart disease and stroke are the major killer diseases and accounted for 15.2 million deaths in 2016 and have been the leading causes of death worldwide in the last fifteen years.[1]

Heart attacks and strokes are typically sudden events mainly caused by atherosclerotic blockage in the coronary and cerebral blood vessels respectively. Strokes can also be caused by rupture of cerebral vasculature resulting in intracranial haemorrhage.[2] Stroke is not only the leading cause of death globally but also one of the principal causes of disabilities in adults. The incidence of stroke has increased over time in certain countries.[3] Despite advancements in diagnosis and management over years, cardiovascular events tend to be a major public health problem.

Risk factors for Stroke and Myocardial Infarction are known, but there is less known about factors surrounding the acute event. Established risk factors for heart attacks and stroke can only partially tell the individual risk and do not foresee the timing and day of the acute event. Identification of patients with controllable risk factors

Corresponding Author:

Mob No: 7973596469
e-mail: vinay.kumari@chitkara.edu.in

is imperative and the avoidance of probable triggers amongst them can be very helpful in prevention of onset of cardiovascular events.

Methodology

A descriptive research design was used to ascertain the risk factors and triggers of cardiovascular events amongst fifty conscious patients admitted in MMIMS & R hospital, Mullana, Ambala, Haryana. Ethical permission was obtained from Institutional Ethical Committee [IEC-961].

The adult patients oriented to time, place and person were interviewed for collecting data regarding Sample Characteristics, Risk Factors, and Triggers using a Structured Interview Schedule within 24 hours of admission. In case, patient was not able to recall in between, help of relatives/ witness was sought. The time taken to collect the data from each patient varied from 15-20 minutes. Structured Interview Schedule developed by the researcher was used and had four sections. Section 1 & 2 comprised of demographic and clinical variables respectively. Section 3 & 4 had questions pertaining to risk factors and triggers related to onset of cardiovascular event respectively.

Risk factors included history of previous cardiovascular events, family history of cardiovascular events, history of hypertension, history of diabetes, hypercholestremia, anemia, smoking, tobacco chewing, alcohol intake. The triggers included time of onset of cardiovascular event, position, activity, smoking 2 hours before the onset of cardiovascular events, drinking 2hrs prior to occurrence of cardiovascular events, physical injury/illness within a week, faced unusual events within a month, heavy meal consumption within 24 hrs prior to onset.

The content validity of the tool was ascertained through seven experts from medical and nursing field. Content validity index (ICVI) of risk assessment sheet varied from 0.75-1 and overall content validity index (SCVI) was 0.87. Content validity index of triggers assessment sheet ranged from 0.75-1 and scale content validity index (SCVI) was 0.89. Reliability of tool was calculated by test retest method (r=.804).

Statistical Analysis: SPSS version 20 was employed to analyses the data. Data analysis was done by using descriptive and inferential statistics i.e frequency percentage and chi-square test. For the present study, the level of significance was $p \leq 0.05$.

Result

Sample Characteristics: Majority of the patients (64%) were more than 50 years of age; 36% in the age group of 35-50 years. Most (66%) of patients were male. Majority (82%) of patients was Hindu and 16% were Muslim and only 2% were Sikh. Most (64%) of patients were vegetarian. Nearly half (46%) of patients were non-literate. About 38% were employed, 32% were housewives, 22% were retired, 4% were farmer and 4% were labourer. All the patients were married. Majority (80%) of the patients belonged to middle/lower middle socio-economic status and lived in rural areas. Most (62%) of the patients were living in nuclear family.

Clinical Parameters: More than half of the patients (54%) had myocardial infarction whereas 46% of the patients had stroke. Ischemic stroke patients (91%) outnumbered the hemorrhagic stroke patients (9%). Nearly 58% of the patients were overweight and obese. Most (70%) had normal Hb followed by 30% of patients had low Hb.

Prevalence of Known Risk Factors: About 24% of patients reported prior history of stroke or myocardial infarction and majority (83.3%) of them had history within one month. Family history of stroke or myocardial infarction was reported by only 3 patients.

More than half i.e 29/50patients (58%) had history of hypertension; nearly 50% were diagnosed within a year and regular intake of antihypertensive drugs was reported by only 17 out of 29 hypertensive patients. One fourth of the patients (24%) had history of Type 2 Diabetes Mellitus; 50% were diagnosed within a year only; majorities (11/12) were complaint to the treatment. About 10% of the patients had history of hypercholestremia. None of the female patients had any history of intake of birth control pills. More than half ie 32/50 (64%) had history of smoking; 23/32 (72%) were current smokers and had been smoking more than 20 years and 11/23 current smokers used to smoke more than 15 cigarettes per day. Four out of fifty patients had history of chewing tobacco.

About 22% patients (11/50) had history of drinking alcohol; 07 were current alcoholics with duration of alcoholism more than 10 years. And more than half (57.1%) of the current alcoholics had binge drinking occasionally. None of patients were currently taking any illicit drug.

Potential Triggers Related To Onset of Cardiovascular events: One third (34%) of patients had cardiovascular event between 6am-11:59am; 22% patients had event in each of the remaining 6 hours time period. Thirty one percent of patients were in sitting position, 26% were sleeping/just awakened and 26% were lying, 8% were defecating/urinating, 6% were in standing position, one patient was busy in farming and other was climbing stairs before the occurrence of cardiovascular event. Most common posture in which cardiovascular events occurred was supine (46%), sitting (30%), squatting (12%) and standing position (12%). About one fourth (24%) of patients smoked 2 hours prior to onset of cardiovascular events and majority (83.3%) of them smoked 4-6 cigarettes. Only one of the patients consumed alcohol 2 hours prior to onset of cardiovascular events and had 2-4 pegs of alcohol. About 26% had physical injury or infection 1 week before the onset of cardiovascular event; 11 patients had fever and two had fracture. One third (34%) had taken some medicine 02 hrs prior onset of cardiovascular events; 12 reported intake of over the counter and 05 had taken prescribed medicines. Six patients (12%) had consumed heavy meal within 24 hours before the onset of cardiovascular event.

Nine patients faced unusual event in the last 24 hrs of onset of stroke; heavy physical activity(4), death in family (03), violent quarrel (02). About 11 (22%) patients were under unusual mental stress within a month prior to onset of cardiovascular events.

A significant association of smoking in 2hrs before the onset of cardiovascular event was seen with type of cardiovascular event, history of diabetes mellitus, anemia. 37% of patients with myocardial infarction had history of smoking 2hrs prior to onset of cardiovascular events as compared to 8.7% of patients with stroke (x^2=5.73; p=0.01). 31.6% of non-diabetic patients had smoked 2hrs prior to onset of cardiovascular events as compared to none of diabetic patients(x^2=4.98, p=0.02). 24% of Non-anemic patients had smoked 2 hrs prior the onset of cardiovascular events as compared to none of anemic patients (x^2=3.94; p= 0.04).

Discussion

In the study, there was one peak timing for the occurrence of stroke. In 34 % of the subjects, peak was between 6.00-11.59 a.m. Chakrabarti et al. found 52% of strokes among Indians occurred between 5-9 am.[4] Vinay et al reported two peak timings for stroke occurrence i.e 5am-9:59am (27.9%) and 3pm-7:59pm (25%). Increase in morning blood pressure[5], aggregability of platelets, blood viscosity and haematocrit may be considered as a causative factor for peak occurrence of cardiovascular events in morning.[6,7]

About one fourth (24%) of patients smoked 2 hours prior to onset of cardiovascular events and majority (83.3%) of them smoked 4-6 cigarettes. 37% of patients with myocardial infarction had history of smoking 2hrs prior to onset of cardiovascular events as compared to 8.7% of patients with stroke (x^2=5.73; p=0.01). 31.6% of non-diabetic patients had smoked 2hrs prior to onset of cardiovascular events as compared to none of diabetic patients (x^2=4.98, p=0.02). 24% of Non-anemic patients had smoked 2 hrs prior the onset of cardiovascular events as compared to none of anemic patients (x^2=3.94; p=0.04). Smoking bans are related with a rapid decline in the incidences of acute myocardial infarction pointing that cigarette smoking is an avertable precipitator of MI.[8] The risk of acute cardiovascular events is higher in the presence of risk factors like smoking, high blood pressure, high cholesterol levels, diabetes or the presence of cardiovascular disease.[9]

About 26% had physical injury/ infection 1 week before the onset of cardiovascular event; 11 patients had fever and two had fracture. A Study supports that recent respiratory symptoms are linked with higher risk of Myocardial Infarction in 1–2 weeks[10] and influenza triggers cardiovascular events.[11]

Nine patients faced unusual event in the last 24 hrs of onset of stroke; heavy physical activity (4), death in family (03), violent quarrel (02). The chances of MI were 5.9 times more (95% CI 4.6–7.7) within one hour of heavy physical work in comparison to periods of lower levels of

activity/ rest.[12] A case-crossover study on ischemic stroke found an association with anger in the two hours preceding symptoms and also exposure to negative emotions during the hazard period was associated with a high odds ratio for ischemic stroke.[13]

About 11(22%) patients were under mental stress within a month prior to onset of cardiovascular events. In another study, 31.4 % of the subjects reported experience of some extraordinary/ unusual event within 24 hours prior to the onset of stroke and unusual mental

stress was the most common unusual event reported by majority (65.9 %) of them.[14]

Six patients (12%) had consumed heavy meal within 24 hours before the onset of cardiovascular event. The relative risk of an acute cardiovascular event in the first hour after intake of heavy meals was seven times higher than the comparable hours on the previous day and four times more than estimated based on the usual frequency of heavy meal intake in the last year.[15]

The findings of the present study suggest that unusual mental stress, Heavy physical activity time of the day, injury/illness within a week prior to the occurrence of stroke, smoking among diabetes may lead to the onset of cardiovascular events. These events can be prevented through modification in life style (refraining from triggers), compliance to treatment and regular follow up.

The study has potential sources of biases which may limit the generalization of findings. The sample size was only fifty and taken through convenience sampling technique. Moreover, the data collection was limited to conscious patients only and collected through self report technique only which may introduce reporting and recall biases. Lack of control group also limits the confidence in the study findings.

Case control studies or case crossover can be undertaken on larger sample for identification of triggering factors related to onset of cardiovascular events.

Nurses have an important role in raising awareness regarding prevention of cardiovascular events and to motivate people at risk to adopt lifestyle modifications. Knowledge of the risk factors and the triggering factors related to cardiovascular events is imperative for the nurses. People having cardiovascular risk factors must be identified and educated about triggering factors.

Targeting Molecular Signals of Cell Cycle and Apoptosis in Anticancer Therapy-Brief Review

Khushboo Kumari[1], Pooja Dubey[1], Raghunath More[2], Varsha More[3]

[1]Research Scholar, Department of Anatomy, Institute of Medical Sciences, Banaras Hindu University, [2]Associate Professor, Department of Anatomy, Institute of Medical Sciences, Banaras Hindu University Varanasi, Uttar Pradesh, [3]Assistant Professor, Department of Kriyasharir, SAS Ayurved Medical College Varanasi, Uttar Pradesh

Abstract

Cancer is a disease that severely affects the human population. The metastasis process of cancer possesses interrelated rate-limiting steps. This paper aimed to provide a brief review on targeting molecular signals of cell cycles and apoptosis which is essence of anticancer therapy. Tumour growth requires a new blood vessel induced by VEGF factor. Loss of heterozygosis occurs frequently at various chromosomal loci in a variety of human cancers. It also discusses the cyclin dependent kinase(CDK)-RB-E2F axis forms the core transcriptional machinery driving cell cycle progressing dictating the timing and fidelity of genome replication and ensuring genetic material is perfectly passed throughout each cell division. Apoptosis involves the activation of caspases which is a group of cysteine proteases and an intricate cascade of process that connect the initiating stimuli to the last termination of the cell. From the review, it was inferred that to target the molecular signals of cell cycle and apoptosis. It might be therapeutic approach for anti-cancer therapy.

Keywords: *VEGF factor, Cyclin dependent kinase,anti-cancer therapy.*

Introduction

Human cancers occur globally. In 2012, 14.1 million cases of cancer were diagnosed worldwide. Among them lung cancer is most common approximately 13% of total new cases diagnosed, while second most common is breast cancer[1]; Cancer is a complicated and multiplying disease include sustaining proliferative signaling[2]. It is difficult to classify because it relies on specific biological insight instead of on methodical broad global and unbiased technique of identifying tumour subtypes[3]. A tumour is an abnormal growth of cells that serves no reason. They can create in any one of the trillions of cells in our bodies. Tumours raise and act differently, depending on whether they are cancerous (malignant), non-cancerous (benign) or precancerous[4].

Characteristics of benign and malignant neoplasm: Usually rapid growth signifies malignancy but many malignant tumours develop gradually. So that growth rate of tumour is not a reliable discriminator between good and bad actor[5]. In most of instances determination of the benign versus malignant is with remarkable accuracy by long-established clinical and anatomical criteria[6]. Differentiation refers to the extent to which neoplasms look like their parenchymal cells of origin, both morphologically and functionally[4]. Malignant neoplasm's exhibit a wide range of parenchymal cell differentiation, most of them exhibit morphologic alterations. Tumourscomposed of undifferentiated cells are called anaplastic, it is a reliable feature of malignancy. Anaplastic cell shows some morphologic feature like-Pleomorphism, hyperchromatism (dark-staining), difference in nuclear size and shapeor unusually prominent single or multiple nucleoli[7].

Local Invasion: The growth of cancers is accompanied by progressive infiltration, invasion, and devastation of adjoining tissues, whereas most benign tumours raise as cohesive expensive masses that stay to their sites of origin[8]. There is a lack of demarcation in benign vascular neoplasm such as hemangiomas, few benign tumoursare neither encapsulated and nor discretely defined· The most reliable distinction between malignant and benign is the development of metastases and invasiveness[7].

Metastasis: Metastasis is defined by the spread of a tumour to sites that are physically irregular with the primary tumour and clearly marks as a malignant tumor[9]. Invasive property allows them to penetrate into blood vessels, lymphatic and body cavities providing opportunities for spread. There are three pathways of malignant neoplasm spread: (1) seeding within body cavities, (2) lymphatic spread, or (3) hematogenous spread[10]. Carcinomas preferred lymphatic spread, while hematogenous spread is preferred by sarcomas[11].

Precancerous Conditions: Abnormal cells without treatment may develop into cancer; these types of abnormal cells are precancerous cells. Some of these cells have mild changes that may vanish without any treatment.The precancerous condition takes long time to develop into cancer. On the basis of mild and severe changes precancerous changes can be described[12].

Hyperplasia means that in comparison to normal cells, abnormal cells are dividing and increasing rapidly[13].

Atypia means that cells are slightly atypical. Occasionally atypia may be caused by healing and inflammation but some types of atypia are precancerous[4].

Metaplasia means, Cells seem normal but they aren't the kind of cells that are usually found in that tissue or area. Metaplasia is associated with cancer so that metaplastic change is often viewed as a premalignant condition that necessitates immediate intervention. Some types of metaplasia are precancerous but not all[14].

Dysplasia is a precancerous condition. Under microscope cell appear to be abnormal in the case of dysplasia. Epithelial dysplasia of cervix (cervical intraepithelial neoplasia) consisting of an increased population of immature cells that are restricted to the mucosal surface has not invaded through the basement membrane to the deeper soft tissues[15].

Genomic Involvement: If normal genes promoting cellular growth through mutation, and are unregulated, hence they termed oncogenes. Multiple oncogenes, along with mutated genes or tumour suppressor gene will all act in concert to root cancer[16]. Proto-oncogene is a normal gene that could turn into an oncogene and involved in signal transduction and execution of mitotic signals, usually through their protein products activates mutation and it becomes a tumor-inducing agent. Proto-oncogenes are RAS, WNT,MYC,ERK and, TRK. The MYC genes codes for extensively used transcription factors[17]. Bcr-Abl genes are example of an oncogene that found on the Philadelphia chromosome. A piece of genetic material seen in chronic myelogenous Leukemia caused by the translocation of pieces of chromosome 9 and 22[18]. Bcr-Abl codes for a tyrosine kinase which is constitutively active leading to uncontrolled cell proliferation. Mutation within a proto-oncogene or within a regulatory region can cause alteration in the protein structure. That will cause an increase in protein activity and a loss of regulation[17].

Tumour growth requires the formation of new blood vessels: Newly formed blood vessels invade the tumour and nourish it. This process is called angiogenesis. Unbalanced and local over expression of small numbers of growth factors particularly VEGF-A helps in tumour vasculature induction[19]. Tumours generate six different types of a new blood vessel, that are different from the normal vasculature, organization, structure and, function[20]. Current anti-VEGF/VEGFR approaches more likely to target only a subset of angiogenic tumour blood vessels, that is, MV and GMP,that is dependent on exogenous VEGF-A[21]. Basic fibroblast growth factor(bFGF) transforming growth factor α (TGFα) and vascular endothelial growth factor (VEGF) which are secreted by many tumours, all have angiogenic properties[20]One of the mysterious aspects of angiogenesis is that a primary tumour will often secrete a substance that inhibits angiogenesis around secondary metastasis. In this case, surgical removal of the primary tumour may stimulate the growth of its metastatic second tumors[22].

Cell cycle and its checkpoints: The cell cycle is a series of events in which cellular components are doubled then cell divides and become two identical daughter cells. The cell cycle involves regulated cell growth replication and division[23]. The cell cycle encompasses four distinct phases G1(gap phase 1) S(DNA synthesis) G2(gap phase 2) and M(mitosis). Cell

cycle regulation both activation and inhibition rely on specific cell cycle checkpoints[24]. The cell cycle checkpoints controlled by the complex interplay of cyclin dependent kinase(CDK-1, -2, -4, -6,-8,-12)and cyclins (cyclin-A, -B,-D,-E). Checkpoints include the G1/S checkpoints and the G2/M checkpoint of particular significance. $P^{21}$and P^{27}functions as a regulator of the G1/S checkpoints[24]. These checkpoints are significant in the setting of DNA damage. DNA damage activates these checkpoints that force the cell to start programmed cell death, and certain the genomic integrity by repairing damaged DNA[25].

Apoptosis: Apoptosis is a distinctive and important mode of "programmed" cell death, which involves the genetically determined elimination of cells. Apoptosis is a homeostatic process occurs normally during development and aging to maintain cell population in tissues[26]. Apoptosis also occurs as in immune reaction or when cells damaged due to disease or lethal agents as a defence mechanism. Both physiological and pathological there isa wide variety of stimuli and conditions that can trigger apoptosis but not all cells will necessarily die in the response of the same stimulus[27]. Irradiation or chemotherapy results in DNA damage in a cell that can promote apoptotic death through a p53-dependent pathway. Hormones like corticosteroid may lead to apoptotic death in some cells (e.g. thymocytes)[28]. There is also the issue of distinguishing apoptosis from necrosis, two processes that can occur independently, sequentially, as well as simultaneously[25].Apoptosis is a coordinated and often energy-dependent process that involves the activation of a group of cysteine proteases called "caspases"[29].

Apoptotic Pathway: Apoptosis can be triggered by numerous types of signals and factors. These are Fas ligand tumour necrosis factor, growth factor withdrawal, viral or bacterial infection, oncogene irradiation, ceramide and,a chemotherapeutic drug. Often these signals are cell type-specific, even if these signals vary from cell to cell.The morphological changes characteristic of the apoptotic process is primarily due to the family of cysteine proteases[30] e.g. caspases that act as effectors of the cell death pathway. Their activation leads to the cleavage of specific proteins that comprise lamins, topoisomerases, DNA dependent protein kinase (DNA P/K), poly(ADP ribose) polymerase(PARP) and a little cell cycle regulators[31]. Mycs function in cell proliferation and apoptosis has been studied extensively. It was proposed that myc directly activates genes involved in proliferation and apoptosis[30]. Mitogens stimulate mycs proliferation pathway, while anti-apoptotic factors such as Bcl-2 shut down Mycs apoptotic pathway when other signals inactivate these anti-apoptotic factors Myc induces cell death[32].

Role of caspase in the regulation of apoptosis: Human caspases are divided into two groups. group I possess caspase-1, -4 & -5, that are involved in cytokine mutation,while group II caspases are involved in the regulation of apoptosis. Group II caspases can be divided into two classes: initiator and effector caspases[31]. Initiator caspases are caspase-2, -8, -9 and -10. Effector caspases are caspase-3,-6 and -7. Effector caspases are produced as dimer in cells.Initiator caspases are produced as monomeric zymogens.The Formation of multi-component complexes triggers initiator caspase dimerization enough for their activation. The death-inducing signaling complex (DISC), the apoptosome and the p53-induced protein with a death domain (PIDD) are protein assemblage platforms that can employ caspase-8/-10, -9 and -2, respectively[33]. There are two apoptotic pathways, the extrinsic receptor-mediated and intrinsic mitochondrial pathway. In the former, extracellular ligands excite receptor oligomerization and DISC gathering whereas, in the latter, proteins from the Bcl-2 family control the release of factors occupied in apoptosome formation through preservation or disruption of mitochondrial integrity. Inhibitor of apoptosis proteins repress the proteolytic activity of caspase-9 and -3[34].

CDKs in anti cancer therapy: Targeting CDKs is a major concern for anticancer therapy.Because of the frequent perturbations in human malignancy and the observation that cell cycle arrest by CDK inhibition could induce apoptosis[35].

Interphase CDKs: Interphase CDKs (mostly CDK 4 and CDK 6) and their regulators have often been found to be mutated in human cancers[35]. The causal role of alteration in tumor development is still hard to access, even though we are well aware of the over expression of these CDKs in different malignancies[34]. CDK4 and CDK6 are over expressed in several malignancies like sarcoma, glioma, breast tumors, lymphoma and, melanoma[36].

P53: One of the most important tumour suppressor protein is P53.TP53 is the most frequently mutated gene in human cancer. These mutant P53s have both lost

wild-type P53 tumoursuppressor activity and gained functions that lead to malignant progression[37]. Frame shift or nonsense mutations are responsible for the loss of P53 protein expression. However, more frequently, the tumour-associated alterations in p53 consequence in missense mutations, leading to the substitution of a single amino acid in the p53 protein that can be firmly expressed in the tumour cell[38]. These substitutions happen throughout the p53 protein, but most frequently cluster within the DNA binding region of p53, with six "hotspot" amino acids that are most frequently substituted. These mutations generally lead to diminution of the wild-type activity of p53.It becomes clear that at least some of these mutant p53 proteins originate to a more aggressive tumour profile, signifying that they have acquired a novel role in promoting malignancies[37].

Conclusion

In this review article regarding precancerous condition, metastasis, role of CDKs in cancer apoptotic pathway, Cell cycle and its checkpoints discussed in detail. The focal point in this review is to trace out the root cause of cancer and trace the effective bimolecular target as therapeutic approach for cancer. Using different prospect it is concluded that cancer is basically the abnormal uncontrolled cell growth. There are different cell check points that control cell cycle at different phases of cell cycle(G1,S, G2,M), like cycline dependent kinase(CDK-1,-2,-4,-6,-8,-12). G1 and S checkpoints are regulated by P^{21} and P^{27} function. These checkpoints are significant in setting DNA damage. DNA damaging is an important key factor for regulating cell cycle by cell checkpoints. There are deferent pathways for apoptosis like P53 dependent pathway, Fas or TNF dependent pathway, caspase and BCL-2 regulating apoptotic pathway. Caspase activity is essential for tumor suppressor functions, with the exception of caspase-8. The combined apoptotic effect is result of all caspases rather than the single-member for the prevention of tumour-genesis.

Visual Outcome After Cataract Surgery: A Review of Literature

Ragni Kumari[1], Mrinal Ranjan Srivastava[2], Pragati Garg[3], Rajiv Janardhanan[4]

[1]Assistant Professor, M. Optom, MBA(Hospital Management), Department of optometry, Era University, Lucknow, Uttarpradesh, India, [2]Assocciate Professor, MD, Community Medicine, Department of Community Medicine, Era Lucknow Medical College & Hospital, Era University, Lucknow, Uttarpradesh, India, [3]Professor & Head, MD, Opthalmology, Department Of Ophthalmology, Era Lucknow Medical College & Hospital, Era University, Lucknow, Uttarpradesh, India, [4]Professor & Head, PhD, Institute of Public Health, Amity University, Noida, Uttarpradesh, India

Abstract

In the developed world expectations about the quality of postoperative unaided vision are high. However, the refractive outcome is not always as predicted (so called refractive surprise), and patients who had not previously required glasses for distance vision but who require them after surgery can be extremely disappointed. Procedures to deal with this eventuality are available (such as exchanging the intraocular lens or adding another one and refractive laser surgery), and these may be appropriate depending on individual circumstances. In the developing world, the impact of rapid visual rehabilitation compensates for the extra cost of the intraocular lens used in the procedure. Worldwide, cataract is the single most important cause of blindness, and the second most common cause of moderate and severe vision impairment (MSVI) according to the Global Burden of Disease, Injuries and Risk Factors Study. Cataract contributed to a worldwide 33.4% of all blindness and 18.4% of all MSVI[3]. These figures were lower in the high income countries (<15%) as compared to South and Southeast Asia (>40%)[3]. Since 1990 to 2010, the number of blind and visually impaired people due to cataract decreased by 11.4% and 20.2%, respectively, and the age consistent global prevalence of cataract related blindness and MSVI reduced by 46% and 50%, respectively[3]. During the same period, the total number of cataract surgeries more than tripled in the world and the Cataract Surgical Rate (CSR) increased in all regions, particularly in Asia, with improvement of surgical techniques and a lower rate of complications[4,5].

Keywords: *Cataract, Surgery, Outcome, Visual Acuity, Impairments, Phacoemulsification, Extra Capsular, Intra Capsular, Right, Sight, Comprehensive.*

Introduction

In 1999 "VISION 2020: The Right to Sight" is a collaborative global initiative by the World Health Organization (WHO) and the International Agency for the Prevention of Blindness (IAPB) with the twin aims of eliminating avoidable blindness by the year 2020 and preventing the projected doubling of avoidable visual impairment[1]. The WHO GAP adopted proven measures for cataract surgical service delivery are cataract surgical rate (CSR – number of cataract surgeries performed per year per one million population) and cataract surgical coverage (proportion of people with bilateral cataract eligible for cataract surgery who have received cataract surgery in one or both eyes at 3/60 and 6/18 visual acuity level).[2]

In India, it has also reported cataract has been reported to be responsible for 50-80% of bilateral blindness.[3,4] While cataract surgical rate (CSR) is one of the major WHO indicators (WHO recommends an ideal CSR range of 3000-5000 per year per million population to meet the need), cataract surgical coverage (CSC) measures the proportion of individuals (or eyes) with operable cataract (defined at different presenting visual acuity (VA) cut-offs <3/60, <6/60 and <6/18) who had cataract surgery.[5,6] Globally, Cataract surgery is one of the most commonly performed ophthalmic surgical procedures.[7,8] Recent decades have witnessed technological advances in cataract surgery and transition from intra capsular cataract extraction with aphakic spectacle correction to phacoemulsification and small incision cataract surgery with Intra Ocular Lens (IOL) implantation, and more recently, femtosecond laser assisted cataract surgery. However, despite all these, globally, in most developing countries, there are issues with outcomes of cataract surgeries with poor outcomes ranging from as low as 11.4% to as high as 44%. [9-24] Most of these study setting was rural, [11-13,16,17,19,23] or mix of urban and rural population, [14,15,18,20–22,24] and very few were urban.[9,10] Risk factors identified in some of these studies included increasing age, [12,15] female gender,[9,24] having no education, [15,19,18] rural residence, [14,15,17,18], operated in government sector, [15,17] having free surgery, [12,17] and presence of aphakia.[9,17,18] In India the 'camp based surgeries' gave way to 'hospital based surgeries' which resulted in better outcomes after cataract surgery, over time.[12,14] In India over 6.3 million cataract surgeries were performed during 2013–2014.[25] Being the most commonly performed surgical procedure that impacts blindness prevention strategies; several researchers have highlighted the importance of monitoring cataract outcomes [26,27]. India, owing to the large size of the country, with huge regional variations in terms of coverage and outcomes,[9,12,14,17,18,28,29] regional surveys are required for local planning of eye care services.[26] In the year 2011–12, we undertook large population based cross sectional studies using rapid assessment (RA) methodology in one urban (Vijayawada in Krishna district) and two rural locations (Khammam and Warangal district), in the south Indian state of Andhra Pradesh, among those aged 40 years and older.[41] In this review we report visual outcomes, causes of VI and risk factors for poor outcome following cataract surgery in this population. Though different outcome based studies in India had both urban and rural population,[14] only Chennai Glaucoma Study (CGS)[18] reported the urban and rural differences in outcomes. The overall prevalence was 11.8% and was comparable with some of the studies done in India[9,12,14,17,18,29] but higher than those reported from neighboring countries such as Nepal, Bangladesh and China.[10,11,16,35] Unlike, CGS, there was no difference in the prevalence of cataract surgery in urban and rural areas (11.9% versus 11.5%; p = 0.56), suggesting an increase in uptake of surgeries in rural areas too. In India, 56.3% of surgeries were done in female patients. [12,14,15,17,18,29] With increasing age was a risk factor for poor outcome and it is likely that with increasing age,[9,12,14,17,18,28,29] there are other co-existing morbidities, which could affect outcomes. The major cause of MVI in urban and rural areas was refractive error followed by posterior segment disorder in urban areas and surgery related complications in rural areas. The major cause of blindness in both urban and rural areas was posterior segment disorder uncorrected aphakia and surgery related complications.[24,29,17,18,28,29,36]

Visual Outcome in Different Studies: A study done by Harpreet Kapoor *et al.* in 1999 and 6383 eyes operated in camp. At discharge with standard aphakic spectacles, poor visual outcome (less than 6/60) was seen in 11.2% of eyes after ICCE, 11.8% of eyes after ECCE without IOL, and 5.7% of eyes after ECCE with IOL, while good vision (6/18 or better) was found in 44.5% of the eyes which underwent ECCE with IOL, 29.4% having ECCE without IOL and 21.6% having ICCE with aphakic spherical glasses.[37]

One more study done by R Anand *et al.* in 2000 in rural Punjab. Of the 428 operated eyes 45.3% gained good vision, 37.85% had low vision and 16.82% were blind. Without sufficient refractive correction only 32.7% of the operated eyes had visual acuity of 6/18 or better. Refractive correction with aphakic glasses and pinhole enabled 45.3% of the operated eyes to see 6/18 or better.[38]

Similar study done in Pakistan by A R Malik in 2003, 181 patients. The type of cataract operations they had had were ECCE in 50%, phacoemulsification in 11%, ECCE with intraocular lens (IOL) in 17% and phacoimulsification with IOL in 22%. At presentation, 49.7% had poor functional vision; after refraction 68% had a good visual outcome.[39]

In 2011, study done in Ibadan by O.O. Olawoye at. el , A total of 184 patients were enrolled for the study. 17.4% had severe visual impairment (VA <6/60 – 3/60)

while 7.1% had borderline vision (VA< 6/18 – 6/60). 1.1% presented with VA 6/18.[40]

In 2016, study done in LVPEI, Hyderabad, and 2049 were randomly selected using. The most common procedure was SICS with PCIOL (Posterior Chamber Intra Ocular Lens) 91.8%. 61.8% had good outcome and based on Based Corrected Visual Acuity (BCVA), 91.7% had good outcome. Based on Presenting Visual Acuity (PVA) and BCVA, those with less than 6/60 were only 2.9% and 1.6% respectively.[41]

As per Mohammed Seid Hussen et al.(2017), 223 cases were evaluated. Nearly, 99% of cataract-operated eyes had poor vision preoperatively (<6/60). 26.6% achieved good visual acuity (≥6/18), 28.9% of them had borderline acuity (<6/18–6/60), and the remaining of 44.5% were remained as poor visual acuity (<6/60).[42]

A study done in Ghana in 2018 by E Kobia-Acquah et al. and total 100 patients were operated. After 1 month, 21.69% had visual acuity of 6/18 or better, 48.19% had a visual acuity of 6/60 - 6/24 and 30.12% had a visual acuity worse than 6/60. Further, 22.89% had visual acuity of 6/18 or better, 48.19% had a visual acuity of 6/60 - 6/24 and 28.92% had a visual acuity worse than 6/60 after three months.[43]

Conclusion

In the developed world expectations about the quality of postoperative unaided vision are high. However, the refractive outcome is not always as predicted (so called refractive surprise), and patients who had not previously required glasses for distance vision but who require them after surgery can be extremely disappointed. Procedures to deal with this eventuality are available (such as exchanging the intraocular lens or adding another one and refractive laser surgery), and these may be appropriate depending on individual circumstances. In the developing world, the impact of rapid visual rehabilitation compensates for the extra cost of the intraocular lens used in the procedure.

New Born Care Practices in a Resettlement Colony of Delhi

Neha Taneja[1], Sujata Gupta[2], Vinoth Gnana Chellaiyan[3], L. Fasna[4], Mrinmoy Adhikary[5]

[1]Assistant Professor, Amity School of Public Health, Greater Noida, Uttar Pradesh, [2]Senior Resident, North Delhi Municipal Corporation Medical College and Hindurao Hospital, New Delhi, [3]Assistant Professor, Chettinad Hospital and Research Institute, Tamilnadu, [4]Assistant Professor, Shri Sathya Sai Medical College and Research Institute, Sri Balaji Vidyapeeth (Deemed to be University), Tamilnadu, [5]Assistant Professor, Murshidabad Medical College, West Bengal

Abstract

Background: Newborn death accounts for 40% of all deaths among the under five children. Most of the newborns are born and die at home in developing country. Newborn health intervention trials at the home and community is identified as one of the key strategy to prevent most newborn death.

Objectives: The study was conducted to assess the newborn care practices and the associated factors among the mothers of resettlement colony in Delhi.

Method: Cross sectional study was conducted among mothers of newborn in an urban slum of East Delhi. Systematic random sampling method was adopted to interview 360 mothers who had live newborns under 28 days old. The data was collected using a pretested, validated and semi structured questionnaire .Appropriate statistical tests were applied.

Results: Among 360 study participants, 206(57.2%) preferred home delivery and 154(42.7%) of deliveries was conducted by skilled birth attendant. 31.1% of newborns were dried immediately. The cord was cut after the delivery of placenta among 189(52.5%) of the newborns. 85.3% of mothers something applied on the cord. 18.1% of mothers discarded colostrum. 81.9% of newborns were given prelacteal feeding. Mothers literacy, birth order, no of antenatal visits, place of delivery were significantly associated with the newborn care practices.

Conclusion: It is observed that detrimental newborn care practices were more common than the beneficial practices in the study. Understanding newborn care practices at home and community level is essential to improve existing intervention to reduce neonatal mortality.

Keywords: *Newborn care practices, neonatal mortality, thermal care, cord care, breast feeding, behavior change strategy.*

Introduction

The newborn period is defined as the first 28 days of life which is exceptionally characterized by transition from intrauterine to extrauterine life. This phase of life has the highest risk of morbidity and mortality [1] Newborn care immediately after birth is of immense importance for the proper growth and development of the baby[2]. It is reported that nearly 3 million babies die within 28 days of life [3] and a further 2.6 million stillbirths each year [4]. India contribution to the global burden of newborn deaths is higher when compared to that of maternal and under-5 deaths. India contributes 16% of global maternal death and 21% of under-5 deaths in which newborn mortality contributes to 27%. The inadequate newborn care practices immediately after the

delivery contribute to the important cause of morbidity and mortality among the newborns[5, 6-8]. Lack of quality antenatal care, unskilled attendant during labor, inadequate thermal and cord care, colostrum avoidance, delayed initiation of breastfeeding poses the main threat to newborn survival in India. Maternal literacy, socio-economic aspects of poverty, the health status of the mother, lack of decision making, self-autonomy, no or less antenatal and postnatal visits, the poor linkage between health centers and community were found to be an unforeseen cause of both maternal and neonatal mortality [1]. The most effective measure in saving newborn especially in developing countries is focusing on household and community level where most newborn death occurs[9]

Essential newborn care (ENC) is a set of measures every newborn baby requires regardless of where it is born or its size. It is designed to protect the newborn in adverse environmental condition and is a framework that should be applied immediately after birth, continued at least for the first seven days[5]. Components of ENC and neonatal resuscitation are proven interventions for reducing neonatal mortality rate and stillbirth rate[10-12] ENC begins during pregnancy- provision of iron/ folate supplements, tetanus toxoid immunization, early identification and management of high-risk pregnancy and maternal infection which has an influence on newborn health and survival. The important strategies of ENC comprises of (a) Basic preventive newborn care such as clean delivery practices, prevention of hypothermia, eye and cord care, early initiation and exclusive breastfeeding on demand (b) Early detection of problems or danger signs (with priority for sepsis and birth asphyxia) and appropriate referral and care seeking and (c) Treatment of key problems such as sepsis and birth asphyxia [10]

Since many births and neonatal deaths take place at home, away from the reach of skilled providers, innovative community-based approaches are instantly needed to bring substantial improvement in newborn survival in India. Hence it is not possible to sustain the whole ENC strategies at the community level but feasible interventions like tetanus toxoid immunization, skilled birth attendant, warming baby, clean cord care and breastfeeding have been identified as proven interventions to save newborn lives [8].Understanding these practices at the domiciliary level can help in designing and improvising existing interventions to reduce neonatal morbidity and mortality [13]. Hence this study was carried out to assess the newborn care practices and the associated factors among the mothers of resettlement colony in Delhi.

Material and Method

A cross-sectional study was carried out among mothers of newborns residing at an urban slum of Delhi of East Delhi. Mothers who had live babies under 28 days old were included and babies with congenital malformation was excluded. Using the prevalence of early initiation of breastfeeding as 36.6% from a previous community-based study [6] conducted, the sample size was calculated to be 356. A total of 360 mothers were recruited for this study. The urban slum chosen was the field practice area of a tertiary care teaching hospital of Delhi. HMIS system has an updated list of newborns. The total population of the slum was 70501 and eligible couples comprised approximately 17.88% of the total population (i.e. n=12605). Systematic random sampling was done with every 5th house chosen and mothers with newborns were covered till sample size of 360 was arrived. As the births and deaths were regularly updated, there was no delay in carrying out the interviews.

A pretested, validated, semi-structured questionnaire in local language i.e. Hindi was used for data collection. The tool has four sections- sociodemographic details, antenatal care and delivery related services cum practices, newborn care practices, and feeding practices. The study tool was pretested with 40 mothers of neonates in a rural area and required changes had been incorporated.

The mothers recruited in the study were explained about the purpose of the study and were given a participant information sheet. The participants were interviewed at their doorsteps with the study tool.

Data entry and data analysis was done in Statistical Package for Social Sciences (SPSS IBM) version 21.0. Data validation checks were done for the data entered. Proportions and mean with standard deviation were calculated. Chi-square test was used to find a difference in proportions. A p value of <0.05 is considered significant. The study was approved by the institutional ethical committee. Confidentiality was secured at all phases of the study.

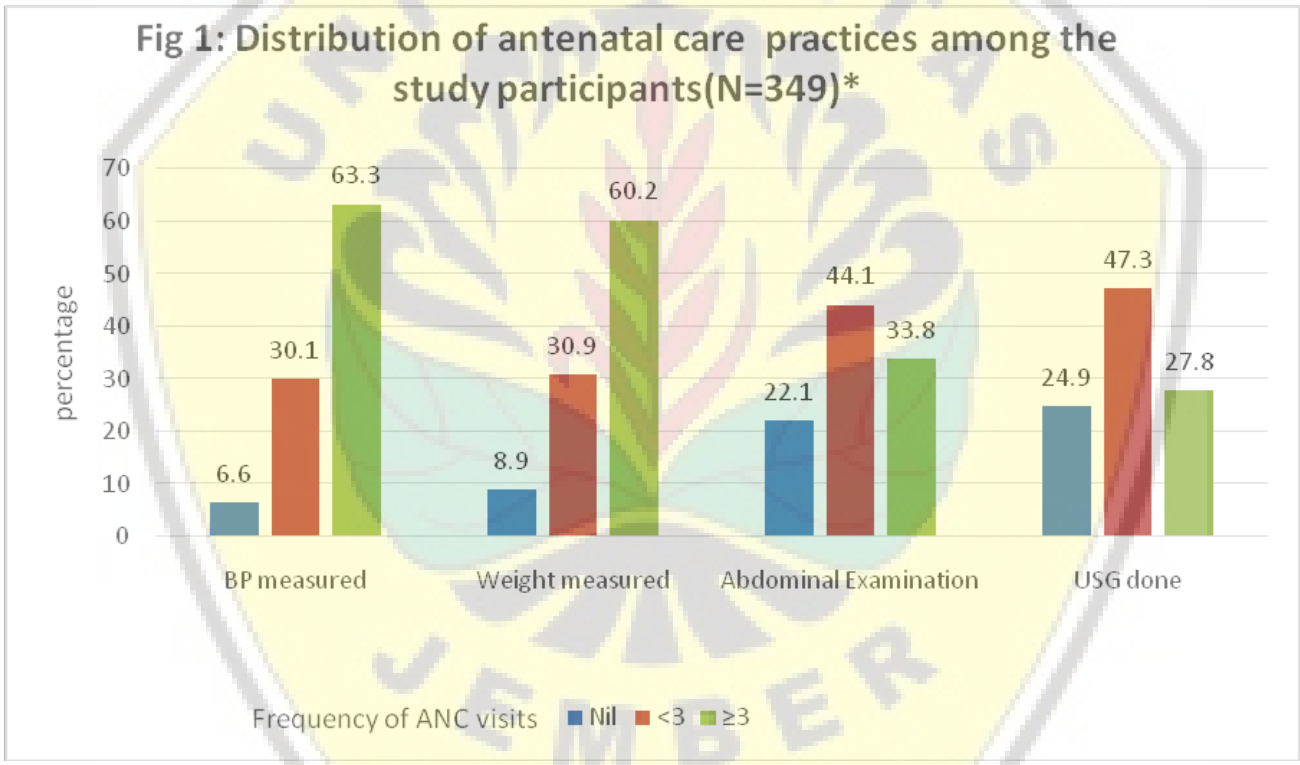
Results

The mean age of the mothers were 24.04 ± 3.69 years. Majority of the mothers were in the age group of

21-30 years. All the study participants delivered a single live baby. Among these 26.4% had given birth to first child whereas 11.7% mothers who had given birth to 5th or more child. The study included 220(61.1%) male and 140(38.9%), female babies. The sex ratio was calculated to be 637 girls born for every 1000 male babies.

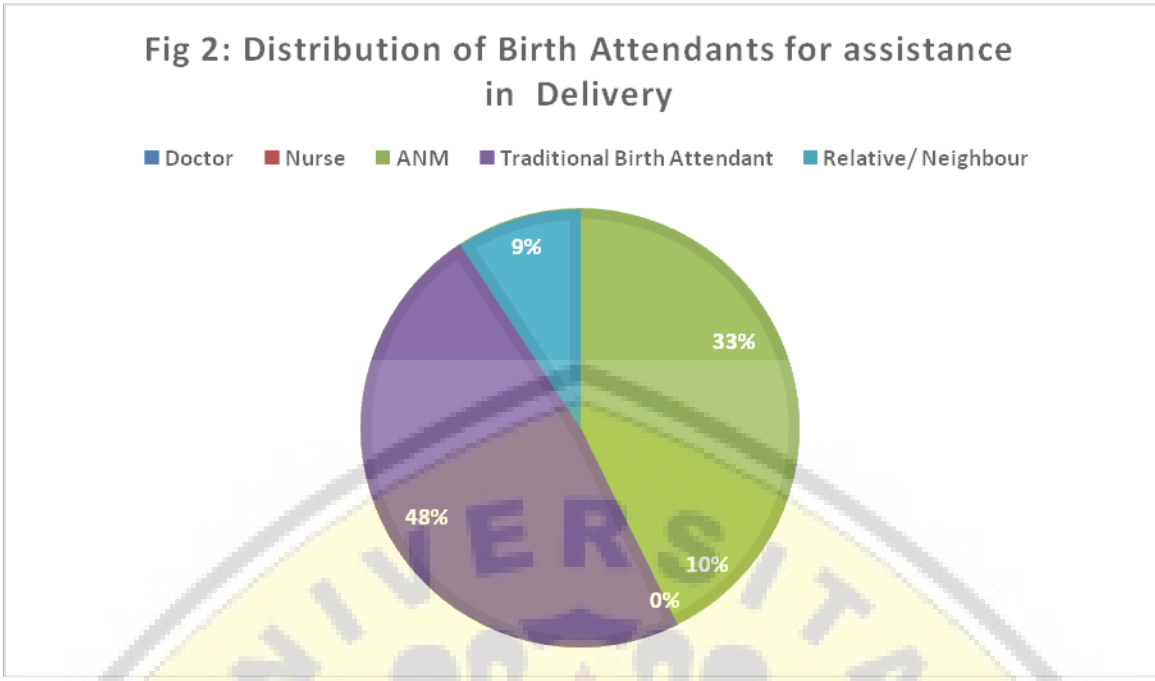
Among the study participants, 113(31.4%) women were illiterate whereas 96(26.7%) women had primary level education followed 151(20.2%) women had the education of middle school and higher level. 73.1% of the participants were of the upper lower class. 54.7% of these belonged to the nuclear family. 52.8% belong to the Muslim religion and 44.2% to Hindu religion.

Out of 360 participants 11(3.05%) did not utilize antenatal services, 61(16.9%) had <3 ANC visits and 288(80%) had ≥ 3 ANC visits.(Fig 1)197(56.44%) women consumed IFA tablets for ≥100 days while 17(4.9%) women did not receive it during their antenatal visits. Two doses of tetanus toxoid (TT) was given to 200(57.3%) women of which 54% were primigravida, 31% was the second gravida and 15% were the third gravida. On the other hand, 145(41.5%) mothers received a single dose of TT of which 68% were of ≥ 3 parity, 29% were of second parity and 3% were primigravidae. Mean estimated gestational age of the newborns was 37± 1.3 weeks.



*The eleven (11) mothers who did not have any ANC visit were excluded

Among the study participants, 206(57.2%) deliveries were conducted in the home. Only 154(42.7%) deliveries were conducted by the skilled birth attendant (doctor, nurse or Auxiliary Nurse Midwife (ANM)) and 206(57.3%) deliveries were conducted by an unskilled birth attendant (untrained traditional birth attendants (dais), family members or neighbors). (Fig. 2) Birth weight was recorded for 252(70%) newborns of which 18.5% of newborns were below 2500gms and 81.5% were above 2500gms.



The mothers were questioned regarding the time of drying of the baby after birth, out of which 190(52.8%) baby was dried after delivery of the placenta and 112(31.1%) was immediately after birth and 47(13.1%) did not know when the baby was dried. 48(13.3%) baby was kept skin to skin contact with the mother after the delivery. All the newborns, except one, were covered immediately after birth. Among 359(99.7%) of the newborns wrapped,93.1 % were wrapped in clean cloth.

The cord was cut and clamped after two minutes of birth among 8(2.2%) newborns. The cord was cut using a new shaving blade among 147(40.8%) newborns followed by scissors 98(27.2%). The most common substances applied on the cord was antibiotic powder in 141(45.9%) followed by oil in 129(42.0%) and haldi in 91(29.6%) of newborns .

Among the study participants, 140(38.9%) mothers initiated breastfeeding within one hour after the birth of the newborn. 65 (18.1%) of mothers discarded colostrum of which 50.8% of mothers considered that giving colostrum is unsafe to the baby. Majority of the mothers (81.9%) has given pre-lacteal feeding within the first three days after the birth. And the most common substances given as pre-lacteals were Janam Ghutti (60.9%), tea (9%) honey (10%), unboiled plain water (10.0%). Other substances are given as pre-lacteals included cow's milk (13.5%) and powder milk (7.0%). Janam Ghutti is an herbal preparation that is given as a bowel cleaner and during bouts of abdominal colic. Only 52(14.4%) of newborns were exclusively breastfed.

In table 1, Univariate analysis was applied on appropriate newborn care practices and antenatal and sociodemographic variables. There was a significant association between mother's literacy, birth order, number of antenatal visits and place of delivery and newborn care practices.

Table 1: Association between newborn care practices and sociodemographic & antenatal factors

Discussion

The present study was carried out with the objectives to determine the existing newborn care practices in a resettlement colony in East Delhi and to identify critical behaviors and barriers that influence the survival of newborns.

The study included 360 participants from resettlement colony among which 349(97%) had only one antenatal visit. This finding is consistent with Nimbalkar et al in which 94.4% of antenatal women had only one antenatal visits in the rural area and 79.9% in urban slums of Gujarat [14]. Among the study participants, 349(96.9%) women who utilized antenatal care on ≥3 occasions, the abdominal examination was done only in 33.8% of participants and ultrasound examination in 27.8% which shows that antenatal care provided was not adequate. 197(56.4%) consumed Iron and folic acid tablets for ≥100 days and 17(4.9%) women did not consume during their pregnancy. According to the National Family Health survey-4 (NFHS-4) 53.8% women in Delhi consumed iron and folic acid for 100 days which is consistent with the present study [15]. 206(57.2%) study participants preferred home delivery and 154(42.8%) institutional delivery, similar findings were reported by Rahi et al in an urban slum of Delhi (43.9%) and Meerut by Ahmad et al in urban slums of Mumbai(16.08%)[16,17]

In 73.6% of the deliveries clean instrument was used to cut the cord which is similar with findings of Baqui et al, where a clean instrument was used to cut the cord in 72.7% deliveries in rural areas of Lucknow[13]. In 115(31.9%) the cord was cut immediately after birth and

189 (52.5%) was cut after the delivery of the placenta. This is similar to the results of Kesterton et al in their study in rural Karnataka where the cord was immediately cut after the delivery [18]. The time of cutting the cord varied with the type of birth attendant at the time of delivery. The cord was cut immediately after birth in 101(65.58%) newborns delivered by skilled attendants (doctor, nurse, ANM) whereas, in the majority of deliveries conducted by unskilled personnel, the cord was cut after delivery of the placenta. Similar results were reported by Kesterton et al from rural Karnataka.[18]

A clean material was used to tie the cord in 301(86.1%) of the deliveries which are higher than the findings of the study done in urban slums of Indore by Agarwal et al [19, 20]. Among the women who were delivered by unskilled birth attendants majority used unsterile material to tie the cord compared to those delivered by skilled personnel. This is consistent with the findings of the study by Rahi et al in urban slums of Delhi where the cord was tied using a clip in all institutional deliveries and sterile thread or a clip (available in delivery kits) was used only in 28.3% home deliveries.[16]

307(85.3%) mothers applied something on the cord. This is similar to the findings of the study by Verma et al in districts of Uttar Pradesh where 83 percent of women reported applying something on the cord stump [21]. 156(50.8%) of study participants used oil/ghee in the cord stump of the newborns. Iyengar et al reported a similar finding of use of ghee or powders and ointments on the cord in a slum and urban area of Chandigarh [19,22]. Majority of study participants(30.5%)delivered by skilled attendant applied nothing on the cord stump as compared to those delivered by unskilled personnel (2.9%). This is consistent with the finding of the study by Rahi et al in urban slums of Delhi where nothing was applied to the cord in newborns born in the institution (86.1%) than those born at home (63%) [16]. The study also showed that education of the mother and delivery by the skilled birth attendant was significantly associated with cord care practices. This finding was similar to that of the study by Baqui et al in rural Lucknow where clean cord care was associated with a maternal education level of secondary school or higher and skilled birth attendance [13].

In this study almost all the newborns were dried after birth to prevent hypothermia among which 112(31.1%) of them were dried immediately after birth and 190(52.8%) of them were dried after delivery of the placenta. Baqui et al reported that in rural Uttar Pradesh 34.8% of the newborns were dried immediately after birth and before the delivery of the placenta. [13, 23]48(13.3%) practiced skin to skin contact with the newborns. A study by Waiswa et al reported that only 2% of mothers practiced skin to skin contact in a rural area [13].Delaying bath helps in preventing hypothermia and infection. In this study 100(27.8%) of newborns was bathed immediately after birth which is lower compared to Rahi et al where 82.6% of newborns were bathed immediately after birth[24] In rural Uttar Pradesh, 26% of newborns were bathed immediately after birth and 56.8% within 6 hours of birth.[13]

Initiation of breastfeeding within one hour of birth was reported by 140(38.9%) mothers and 270(75%) newborns were initiated on breastfeeding within 6 hours of birth. Similarly, early initiation of breastfeeding is reported in urban slums of Lucknow (36.6%), Unnao (5%) and Barabanki districts of Uttar Pradesh (19%) [13, 25, 26].Baqui et al reported from rural areas of Unnao and Barabanki districts a high prevalence of pre-lacteal feeding (95.8%) which is similar to the current study(81.9%)[13,26].

In this study, 18.1% of mothers avoided colostrum. The main reason for avoiding colostrum was that the mothers considered colostrum as stagnant breast milk which had accumulated during the entire period of gestation and so, according to them it could be harmful if given to the newborn. This is similar to the findings in the study by Kesterton et al in rural Karnataka,Gupta et al in urban slums of Lucknow and Mrisho et al in rural Tanzania. [18,25,27].Colostrum avoidance is higher in those mothers delivered by unskilled personnel along with a high prevalence of giving top feed when compared with the delivery conducted by skilled attendants. Differences in colostrum feeding based on the place of delivery i.e. home vs. institution had been documented by Varma et al in Uttar Pradesh where a higher percentage (79%) of women who delivered in an institution fed colostrum as compared to those delivered at home (59%) and this difference was statistically significant ($p< 0.01$).[21]

The prevalence of Exclusive breastfeeding was 14.4% subjects among the study participants which is lower than slums in Indore where Agarwal et al reported the prevalence of exclusive breastfeeding as 44.6%[20]. Early initiation of breastfeeding was more in those newborns who were delivered by skilled personnel

compared to those delivered by unskilled care providers. The differences reflect the gap in knowledge regarding correct newborn care provided by the skilled and unskilled personnel and it further stresses upon the need to involve unskilled care providers in the health system and educate them in context of essential newborn care practices

Recommendations:

1. Increasing awareness and utilization of antenatal care to form an essential component in each pregnant mother and promote institutional deliveries or deliveries by skilled personnel.
2. Community mobilization and behavior change communications if amalgamated together might promote the adoption of evidence-based newborn care practices and increased uptake of neonatal services

Conclusion

This study emphasizes the need for newborn care counseling of the mother during antenatal check-ups. Expanding skilled birth attendance can be viewed as an effective strategy to promote essential newborn care. Various behavioral change communication strategies through mass media and interpersonal education during antenatal visits could be studied for their effectiveness in changing critical behavior and barriers among the mothers and birth attendants. High-risk traditional newborn care practices need to be addressed by culturally acceptable community-based health programs to improve newborn care practices. The findings of our study underline the need for more targeted approaches to change newborn-care practices at home and community level.

A Cross Sectional Study on Prevalence of Anemia in Children Below 5 Years, Kuthambakkam Village, Tamil Nadu

D. Jayashri[1], B. Charumathi[1], Yamini[1], Timsi Jain[2], Ruma Dutta[3], Gomathy Parasuraman[4]

Post Graduate[1], Professor and Head[2], Professor[3], Associate Professor[4], Department of Community Medicine, Saveetha Medical College Hospital, Thandalam, Kanchipuram District - 602105

Abstract

Background: Anemia deficiency is a significant public health problem that occurs worldwide in both developed and developing countries. Iron deficiency anaemia in children has been linked to increased childhood morbidity and impaired cognitive development and school performance. Children between 5 and 12 years of age are at a critical stage of intellectual development, and optimization of their cognitive performance during this period could have life-long benefits.

Objectives: To estimate the prevalence of anaemia among children below five years of age in Kuthambakkam village and to find the factors associated with anemia among study participants.

Material and Method: A Cross sectional study conducted among Children below 5 years of age in Kuthambakkam area. A pre-tested questionnaire, clinical examination was done to find out anemia among study subjects. The sample size calculated was 150.Dataanalysis:Proportions and chi-square was used for analysis.

Results: The prevalence of anemia was found to be 37(25.17%).

Conclusion: Measures for treating anaemia should also be strengthened; doses should be modified according to the current anaemia status of the children.

Keywords: *Anemia, Prevalence, children.*

Introduction

Anemia deficiency is a significant public health problem that occurs worldwide in both developed and developing countries. Approximately 300 million children globally had anemia in 2011.[1] and 50% of anemia cases are caused by iron deficiency.[2] Anemia is defined as a condition in which the number of red blood cells or their oxygen carrying capacity is insufficient to meet physiological needs which vary by age, sex, altitude, smoking and pregnancy status(WHO). It is a common blood disorder and is one of the major disease in India that exists in all age groups especially seen among preschool children and pregnant women.[3]

Low oxygenation of brain tissues, a consequence of anemia, may lead to impaired cognitive function, growth and psychomotor development, especially in children.[4] Infants, under 5-year-old children and pregnant women have greater susceptibility to anemia because of their increased iron requirements due to rapid body growth and expansion of red blood cells.[5]

National Anaemia Prophylaxis Programme (NAPP) has been set up in all states, the benefits have not

yet been appreciated in the target population due to constraints like lack of operational feasibility to estimate the haemoglobin level, orientation of field workers and acceptance of the programme by the beneficiaries. According to National Family Health Survey (NFHS)-4 shows prevalence of anemia among children between 6-59 months age is 59.4% and Tamil Nadu data shows prevalence of anemia 52.3 in rural area.[6]

Anemia is associated with socio-economic, biological, environmental and nutritional factors. The prevalence of anemia within interior parts of India is unknown and due to this lack of information its necessary to conduct a study, which will be helpful in directing the resources to deficit areas,thereby to reduce prevalence of anemia by 3 percent per year among children,adolescents and women of reproductive age group (15-49 years) between 2018-2022.[7]

Objectives:

1. To estimate the prevalence of anaemia among children below five years of age in Kuthambakkam village.
2. To find the factors associated with anemia among study participants.

Methodology

A cross sectional study was conducted in Kuthambakkam village on July 2017 – September 2017. Children between 1-5 years of age were selected by using Simple Random Sampling method. The sample size of 150 children was estimated from the family folder survey details of our rural field practice area of Saveetha medical college. Using a pre-tested questionnaire socio-demographic details, and factors leading to anemia were collected by interviewing the mothers of under 5 year children. Clinical examination was done by looking for pallor at palpebral conjunctiva, nails, oral cavity and tongue to assess the prevalence of anemia in children. Children who were not present in the field at the time of data collection and those who are not willing to participate were excluded from the study. Data was entered in MS Excel.

Results

Cross-sectional study was conducted among 147 children below 5 years of age group of whom 37(25.17%) were found to be anaemic. Among 95 males ,20(21.1%) were found to be anemic and among 52 females 17(32.7%) were found to be anemic.

However no significant association was found with sex, socio-economic status, IFA consumption history and history of deworming. One third of the children are not taking or taking irregularly iron folic acid supplementation.

Table 1- Distribution of anemia among study subjects

S.No.	Characteristics	Anemia Present (%)	Anemia absent (%)	Total	Chi square	P value
1.	**Age**					
	1-3 years	19 (19.6)	78 (80.4)	97	4.719	0.030 (S)
	4-5 years	18 (36.0)	32 (64.0)	50		
2.	**Gender**					
	Male	20 (21.1)	75(78.9)	95	2.417	0.120
	Female	17 (32.7)	35(67.3)	52		
3.	**Socioeconomic status**					
	Upper Middle	10 (27.8)	26 (72.2)	36	1.970	0.579
	Lower Middle	20 (28.2)	51 (71.8)	71		
	Upper Lower	6 (19.4)	25 (80.6)	31		
	Lower	1 (11.1)	8 (88.9)	9		

Discussion

In this Cross-sectional study out of 147 children, 37(25.17%) were found to be anaemic. A study done by Sudhagandhi et al in Kancheepuram district ,results showed that 75.2% of toddlers were anaemic.[8]

A study done by Verma et al, they found that the Prevalence of anemia among male and female pre-schoolers residing in a slum of Delhi was 82.4% and 73.0% respectively.[9]

Conclusion

The Overall Prevalence was found to be lower than the national and state average. Both boys and girls were found to be anaemic. Measures for treating anaemia should also be strengthened; doses should be modified according to the current anaemia status of the children. Mothers should be informed regarding importance of IFA and iron rich food diet for the children.

Limitation: The Hemoglobin level was not estimated in this study.

Conflict of Interest: Nil

Source of Funding: Nil

Ethical Clearance: Ethical approval was obtained from the Institutional Review Board (IRB) and Institutional Ethics committee. Written informed consent was obtained from the parents of the study participants and information sheet regarding the study was given to all the participants.

A Preliminary Investigation of Safety Matters among Secondary Health Care Nurses in Jordan

Abdallah ashour[1], Zuraida Hassan[2]

[1]Ph.D. Student, School of Business Management, [2]School of Business Management, Universiti Utara Malaysia, Malaysia

Abstract

Researchers have characterized safety execution as an essential capacity in deciding the achievement or disappointment of an organization. While, Fatal and non-fatal occupational injuries have turned into a noteworthy worldwide concern and their outcomes to safety and health can be vigorously troubling. This preliminary examination explored the safety issues of nurses in Jordanian emergency clinics to identify potential harm factors. The study aimed to survey the occupational injuries association amidst the working time of Jordanian nurses and their vision of executive support for workplace safety. Thirty-two nurses volunteered and finished the survey — about 81% of reacting nurses some injury. Injuries from sharp devices were accounted for at 25%, trailed by sensitivity episodes risks at 18.8% and back agony related issues at 12.5%. Most of the specialists felt that an absence of top administration support and insufficient preparing were identified with work environment safety issues.

Keywords: *Safety, Occupational Injuries, Preliminary Study, Jordan, Measurement.*

Introduction

Working environment safety is vital to the ceaseless activity, survival and ideal usefulness of organizations[16,17]. Safety at working environments, work sites and crosswise over different organizational structures is basic to the general execution and corporate presence of organizations[5]. Consequently, researchers, industry specialists and significant partners have both recognized and underscored the requirement for improved safety execution pointers in organizations and related work-settings[6,7,21]. Notwithstanding this call, laborers are as yet looked with various perils that happen through substance, natural, mental and ergonomic exposures[4,13,14]. Thusly, different degrees of accidents, injuries and fatalities all of which represent different dimensions of difficulties to organizations are as yet noted in organizations as markers of poor safety execution[8].

In 2015 alone, there were 2.40 million passings because of fatal business related diseases. As indicated by the International Work Organization (ILO), current worldwide insights today demonstrate an expected yearly 2.78 million fatalities in work environments because of poor safety frameworks, the board rehearses, human-blunder factors and basic wasteful aspects. In synopsis, gauges recommend that 7,500 individuals bite the dust each day. Of this aggregate, 1,000 bite the dust from occupational injuries and 6,500 bite the dust from business related sicknesses[11]. Regarding non-fatal occupational injuries around 374 million people over the world are included yearly[14,16].

The results of these worldwide measurements are that the monetary expense of work environment accidents, injuries and fatalities are very disturbing and are a reason for worry in tending to the issues of safety in work places. As Takala et al. (2014)[24] noticed, the financial expense of safety changes somewhere in the range of 1.8% and 6.0% of the Gross Domestic Product (GDP) of different nations.

Middle East: In the Middle East and in Jordan accidents in the working environment have been of worry to researchers and industry professionals alike (Eskandari et al., 2017)[9] in light of the fact that death rates are believed to be higher than in different pieces of the world [15]. For instance, in 2006, Hämäläinen determined that fatal occupational rate per 100,000 was

20.0 in Middle East Sickle nations, when contrasted with 16.1 per 100,000 in Built up Market Economies like Europe and the US and 13.1 per 100,000 in Previous Communist Nations. Just other Asian Nations like Bangladesh, Pakistan and Thailand at 23.1 per 100,000 and sub-Sharan Africa at 21.0 per 100,000 were appraised as more [12].

Jordan: In Jordan, the health part is a dangerous working environment on account of its unpredictability and the dynamic idea of development exercises. Sadly, exact figures are hard to acquire as a decent database and sufficient method for gathering information are missing [3,7]. From an investigation that for the most part depended on government managed savings figures, the occupational fatality rate of Jordan was assessed as 25 for every 100.000 every year for the period from 1980 to 1993 [23]. Different investigations have discovered lower rates. The ILO evaluated a fatality rate of 15.6 in Jordan for 2006 and the rate was required to be about 12.0 somewhere in the range of 2008 and 2014 [7]. In an investigation of clinic confirmations from three noteworthy medical clinics utilizing information from 2008 to 2012, Al-Abdallat, Oqailan, Al Ali, Hudaid and Salameh (2015)[2] evaluated a fatality rate was 2 for every 100.000 specialists. Likewise, they explicitly noticed a 1.1% fatalities rate among Jordanian healthcare specialists versus different classes of laborers. Thinking about this situation in scientific terms, occupationally-initiated fatalities rate among Jordanian health specialists could be high in relationship to the quantity of health care laborers in Jordan.

In 2017, Mohammed Hussein, Administrator of the Arranging Advisory group of First International Jordanian Gathering for Occupational Health and Safety, said that "the international specialist demise rate has expanded in the course of recent years and is probably going to be higher in this area" [1] . These conflicting assessed rates exhibit a key trouble in inspecting the issue of working environment safety in Jordan. That is the nonappearance of relevant information for working environment damage reports, which makes concentrating the issue of work environment injuries and fatalities troublesome. As Dababneh et al. (2018)[7], noticed an "absence of a decent and refreshed database and the nonattendance of a reasonable and solid instrument for gathering, recording and investigating information, make the genuine size of business related injuries and misfortunes substantially more than what is distributed in our official reports" (p. 162).

Method

Subject and study population: The need and irregularity of information in the Jordanian setting are available in all divisions of the Jordanian economy, including healthcare. To elucidate the issue in the Jordanian healthcare setting, the scientist led a fundamental examination of few people from among the objective populace as Kanter, Tsai, Holman and Koerner (2013)[19] and Frohm, Lindström, Winroth and Stahre (2006) recommended. This starter think about was led from spring to April 2018 among 32 nurses utilizing a review. All nurses engaged with this examination were Jordanian.

Survey: A lot of the reviews were disseminated to the respondents for to pick up data from nurses about potential organizational hazard factors, saw work environment perils and damage because of danger presentation at the work environment. The review session was completed by and by to the respondents after a short introduction to assemble data from the respondents. The nurses were sufficiently educated and knew about the reason for the investigation. They were likewise made to understand that cooperation in the review was deliberate and under severe privacy.

Data analysis: This review investigated the fundamental aftereffects of nonfatal occupational damage among Jordanian nurses. Thus, the measurable examination associated with this investigation will just contain spellbinding information results. This is because of a proposal by different creators in past writing who expressed that any fundamental examination ought to be for the most part enlightening [20]. The underlying outcomes were collected from profiling information of respondent's epidemiological information including socio-statistic data, working profile, way of life, health status and injuries data.

Results

Socio-demographic data and work profile: All respondents who volunteered to take an interest in this fundamental examination were Jordanian nurses. Thirty-two overview instruments were picked up as a totally addressed Starter Investigation of Working environment Safety review.

Among the members, 65.6% were male, 34.4% female and 40.6% were between 22 to 50 years of age. The normal period of harmed specialists was around 31

years of age. The vast majority of them (43.8%) have gotten and finished formal instruction and have moved on from nursing school. Additionally, the greater part of them (96.9%) worked all day days amid the week with a normal of 8 hours per day.

Occupational Injury Information: Occupational damage data was acquired from this fundamental study of the Jordanian nurses. Of the 32 respondents, twenty-six (26) asserted that they had encountered damage in the previous three months while working in the medical clinics. The predominance rate for damage events among nurses in Jordanian medical clinics was 81.3% as appeared Table 1.

Table 1: Nurses experiencing any injury in the past 3 months

	Frequency	Percent	Valid Percent	Cumulative Percent
Yes	26	81.3	81.3	81.3
No	6	18.8	18.8	100.0
Total	**32**	**100.0**	**100.0**	

Table 2. Socio-demographic of injured workers and types of experienced injury (n=32)

	Characteristic	Frequency	Proportion (%)
Age	22-30 years	14	43.8
	31-40 years	13	40.6
	41-50 years	5	15.6
Gender	Male	21	65.6
	Female	11	34.4
Types of injury experienced	No injury	6	18.8
	Back pain	4	12.5
	Sharp tool injury	8	25.0
	Infection	2	6.3
	Slipping	2	6.3
	Allergy Incidents	6	18.8
	Others	4	12.5

The normal reason for injuries was from needle stick and sharp device injuries (25%), hypersensitivity occurrences (18.8%) trailed by back torment (12.5%). The greater part of the laborers guaranteed that injuries were brought about by falling (6.3%) and radiation or medicine introduction (15.6%). The lower body was accounted for as the most widely recognized site influenced by injuries (12.5%). The seriousness and recurrence of non-fatal occupational damage were estimated dependent on the respondents' self-report. There was a redundancy of similar injuries at a similar three months which was demonstrated by short of what one damage events in a year. Table 2 abridges the outcomes.

Perceptions of Workplace Safety and Health: The analyst studied 32 representatives crosswise over various clinics in Jordan about their impression of safety in the work environment safety. Those things were positioned dependent on recurrence of event and the outcome is appeared as follows.

The outcomes for laborers in the Jordanian emergency clinics were frightening. Most of nurses detailed that an absence of enthusiasm for preparing nurses in crises (62.5%) was the primary danger in their work environment. About 56.3% of nurses felt that safety took a rearward sitting arrangement to their assignments and 75% trusted that safety is to a lesser extent a need at their working environment. As for the executives, 59.4% nurses announced that administration did not indicate care about the safety of nurses and that administration did just the base legally necessary to protect representatives. About 56.3% said nurses were hesitant to report safety issues. These discoveries could be utilized as a pointer that administrators and chiefs must be increasingly proactive with regards to working environment safety.

Other key findings from workers across all industries include:

- 31.3% said that the health and wellbeing of nurses was advanced at work.
- 37.5 said safety preparing is a piece of each new worker's introduction.
- 40.6% detailed everybody is associated with settling work safety issues.

Discussion

This primer examination found that pervasiveness rate of non-fatal damage events among nurses in Jordanian emergency clinics was 81.3% in a quarter of a year preceding the study and that youthful specialists had higher damage rate than the general rate. Most of specialists felt that an absence of top administration support and insufficient preparing were issues. In this way, safety preparing, safety advancement and work association of supervisors ought to be used to lessen the issues.

Conclusion

Safety execution starts with the act of safety the executives. Nurses need to see that their chiefs and friends' proprietors are proactive and care about their prosperity. Hazardous practices will in the end influence the safety levels and budgetary returns. The discoveries of this primer examination fill in as a marker for bosses and directors to be increasingly proactive with regards to working environment safety and as a spring board for a progressively total investigation. The strategy including the study instrument give a pathway and rules to a directing a future increasingly far reaching study using a bigger example.

Acknowledgements: The author might want to thank the respondents of Jordanian nursing who engaged with the examination and their medical clinics for allowing them to participate.

Conflict of Interest: No conflicts of interest were reported for this study.

Source of Funding: This paper is a self funding and no financially supported for the current study.

Ethical Clearance: This is a preliminary study and no need for ethical clearance.

Outcome of Laparoscopic Assisted Endorectal Pull through Versus Trans Anal Approach in Management of Hirshsprung Disease

Abdelhalem Shawkat[1], Mohamed Elbarbary[1], Gamal Saleh[2], Tohamy Abdallah[2], Ragab Askalany [2]

[1]Pediatric Surgery Department, [2]General Surgery Department, Minia University, Faculty of Medicine, Egypt

Abstract

Aim of the Study: The aim of this study is to compare outcomes for infants with Hirschsprung's disease undergoing a TERPT procedure with those undergoing a laparoscopically assisted transanal pull-through (LAPT).

Method: Forty patients with Hirshsprung Disease were operated between January 2016 and January 2019 were reviewed. Twenty patietns underwent trans anal endorctalpull through TERPT while the other 20 patients underwent laparoscopic assisted pull through LAPT. Age at operation, presenting symptoms, operative time complications and degree of continence were evaluated. Bowel functions were assessed using the Cleveland Clinic Incontinence Score. Ethical procedures including obtaining informed consent were conducted in accordance with the ethical standards of the Committee on Human Experimentation of Minia University.

Results: The mean age of the patients at the time of operation were 18.9 month for the trans anal group versus 21.3 months for the laparoscopic group. The mean follow-up period was 6 month, ranging from 3 to 12 month. The rate of enterocolitis occurred in 15% of cases in trans anal group versus 30% of cases in the laparoscopic group. Constipation was found in 25% of cases of TERPT group versus 10% of cases in the LAPT group. The rates of normal continence (score 0:4) was 60% vs 50% for TERPT vs LAPT respectively while the rate of severe incontinence (score 15:20) was 20% vs 5% for TERPT vs LAPT respectivel.

Conclusion: The functional outcomes after LAPT was satisfactory in term of fecal soiling compared to trans anal approach this may be due to less pelvic dissection comared to trans anal pull through

Keywords: *TERPT, LAPT, Hirshsprung disease, Incontinence.*

Introduction

Since the first description of Harald Hirschsprung's in 1889[1]. The choice of rectal dissection technique is controversial, although the three primary options remain full-thickness dissection with end-to-end anastomosis as described by Swenson in 1948,[2] and Duhamel's retro-rectal anastomosis or Soave's extramucosal dissection which were developed later.[3],[4] During the 1980s, one-stage (primary) procedures were proposed for uncomplicated cases, thereby avoiding the morbidity associated with stoma formation.[5] In 1995, Georgeson *et al*[6] described a minimally invasive approach using laparoscopy for colonic biopsies and mobilisation, followed by transanalendorectal dissection of the rectum and coloanal anastomosis. Subsequently, laparoscopic Swenson and Duhamel-type procedures have been described.[7],[8] In 1998, De La Torre *et al* reported the first entirely transanal primary endorectal pull-through without laparoscopic assistance.[9] The transanal

Swenson-type procedure has been reported but no case-controlled data have been published; a purely transanal Duhamel is not feasible technically.[10]

Benefits of this approach include utilisation of a single incision and the avoidance of abdominal wall scarring, with the potential for better cosmesis and reduced postoperative pain, a shorter operating time and the suitability of this technique for use in resource-poor settings which may lack equipment for laparoscopy.[11–13] Potential disadvantages regarding a totally transanal approach include the possible impact of prolonged dilation of the sphincter muscles on faecal continence,[14,15] the risk of colonic torsion and the inability to confirm the histological transition zone prior to starting mobilisation of the colon as many surgeons would change their operative approach when faced with longer segment aganglionosis.[16]

Aim of the study: The aim of this study is to compare outcomes for Patients with Hirschsprung's disease undergoing a TERPT procedure with those undergoing a laparoscopically assisted transanal pull-through (LAPT).

Patients and Method

The study included Forty patients with HD disease operated on from January 2016 to January 2019 in the department of Pediatric Surgery Minia University . Twenty patients were operated upon using (TERPT) and Twenty patients were operated using (LAPT) .

Inclusion criteria:

1. Age range from 4 month to 12 years
2. Patients suffering from Hirschsprung's disease by their clinical picture, rectal biopsy, with barium enema study.
3. Cases should not have any contra indication for surgery or laparoscopy
4. The study included infants and children with HD disease who fit for surgery.

Exclusion criteria:

1. Age for neonates and above 12 years.
2. Patients with associated co-morbidity
3. Previous surgery for Hirschsprung's disease.
4. Patients with suspected other cause of chronic constipation
5. Patients presented with enterocolitis or obstruction.
6. Patients with associated major gastrointestinal anomalies.

Preoperative evaluation: After detailed history and full physical examination, each patient underwent the proper investigations to confirm the diagnosis and assess the fitness for surgery. Consent is taken after discussing with the parents the details of the procedure, expected benefits and possible intra- and postoperative complications. Also, parents were told that the results of this study will be published, and consent for publication is taken. Detailed history was taken from all of our patients as sown in table 1.

Table 1: Presenting symptoms of patients

Presenting symptoms	Total (n=40)	TA (n=20)	LA (n=20)	P-value
Chronic Constipation	30 (75%)	17 (85%)	13 (65%)	0.14
Delayed meconium passage	28 (70%)	12 (60%)	16 (80%)	0.16
Abdominal distension	15 (37.5%)	9 (45%)	6 (30%)	0.32
Preoperative enterocolitis	17 (42.5%)	8 (40%)	9 (45%)	0.74
Neonatal bilious vomiting	4 (10%)	2 (10%)	2 (10%)	1

Rectal examination for empty collapsed rectum with absent rectal ampulla, tight anal sphincter and impacted stools. Also to exclude signs of enterocolitis. Investigations was done in the form of full laboratory investigations and radiological imaging in the form of Plain abdominal X-ray films erect and supine and unprepared (unprepared to prevent transient dilatation of the aganglionic segment) single contrast enema were done to confirm the diagnosis by revealing the "transition zone" or the funnel shaped area between the narrowed

aganglionic distal segment and the dilated ganglionic proximal segment, with special attention to the lateral views in contrast study for accurate assessment of the distal colorectal segment. Delayed X-ray film after 24 hours if transition zone is not identified. If significant barium is still present in the colon, it increases the suspicion of Hirschsprung's disease. Contrast injection was done under screen to inject a moderate amount of barium. Antero-posterior and lateral views usually taken immediately and delayed films were taken 24 hours later. Anorectalmanometry was not routinely indicated, but rather obtained based on the patient's medical history and underlying illness. Partial thickness rectal biopsy was done for all patients to confirm the diagnosis by the absence of ganglion cells in the diseased segment. These biopsies were taken under general anesthesia before the definitive procedure. Consent for surgery was conducted with the parents or guardians in attendance of the surgeons and anaesthiologist and the whole procedure, regarding preoperative preparation, medications anaesthia and preoperative and postoperative events and complications are explained and discussed.

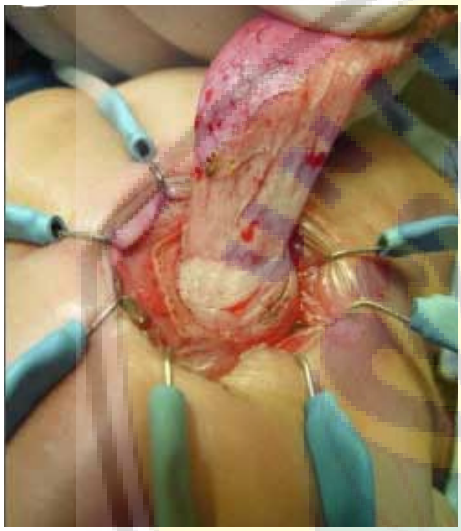

Fig 1: Transanalpull through of the colon

Fig 2: Inspection of the narrow and dilated segments

Results

The mean age of the patients at the time of operation were 18.9 month for the trans anal group versus 21.3 months for the laparoscopic group. Patients were reviewed retrospectively. The mean follow-up period was 6 month, ranging from 3 to 12 month.

The mean operative time was less in the trans anal group in con+trastto laparoscopic group 90 min vs 120 min respectively. The post operative hospital stay was more in trans anal group compared to the laparoscopic group 5.3 days vs 3.3 days respectively. Intraoperative bleeding occurred in only one case of LAPT group vs no cases in the trans anal group. This case was controlled laparoscopically without need to convert to open surgery. Two cases of the transanal group required laparotomy due to inadequate colon mobilization.

Regarding the early post operative complications, none of the cases in both groups developed anal stenosis after dilatation . Three cases 15% developed post operativeenterocolitis in the trans anal group while 5 cases 25% of the cases of the laparoscopic group developed this complication in the early post operative period . Bowel control was assisted for patients older than 3 years. Functional assessment was performed using the Cleveland Clinic Incontinence (CCI) score[13]. In this scoring system, the frequency of incontinence, in addition to the extent to which a person's life is altered, is evaluated using 5 questions assessing the type of incontinence (solid, liquid, gas, wears pad, lifestyle alteration). The frequency with which each type of incontinence occurs is rated on a scale from 0 (never) to 4 (always or 1/day). The frequencies are added to yield a total score, which can range from 0 to 20, with

higher scores indicating higher levels of incontinence. A good outcome was considered when the patient was continent (score 0-4) or had mild incontinence (score 5-9). Poor outcome patients were those presenting with moderate (score 10-14) or severe (score 15-20) incontinence. Regarding our results, In the trans anal group 50% had normal continence,30% of cases had mild incontinence and 20% had severe incontinence while the laparoscopic group had better outcomes regarding the degree of incontinence 70% of cases had normal bowel control,20% had mild incontinence and only 10% had severe incontinence. Episodes of constipation occurred in 25% of case in the trans anal group versus 10% of cases in the laparoscopic group. None of our cases developed abscess formation, intestinal obstruction, intestinal ischaemia, enteric fistula formation.

Discussion

Since the first reports in the late 1990s the transanal pull-through has become a popular procedure worldwide for Hirschsprung's disease management and the role of laparoscopy remains controversial.[12],[17] . Five eligible studies comparing TERPT to LAPT. In general, these studies were of low quality, featuring heterogeneity with respect to outcome assessment, limited adjustment for potential confounders and inadequate long-term follow-up. The only outcome assessed, where there was a significant difference, was duration of surgerywith two studies demonstrating a significantly shorter duration of operation time for TTERPT compared with LAPT similar to our study . This may be due to avoidance of time spent accessing the abdomen with a laparoscopically assisted procedure and concords with results from studies comparing open abdominal procedures with transanal pull-through.[18] It may be likely to be subject to a degree of case selection, it is possible that cases with shorter, less-complicated disease segments were preferentially chosen for TTERPT.

The other relevant outcomes assessed were the incidence of Hirschsprung's associated enterocolitis (HAEC) and functional gastrointestinal outcomes. We found no evidence to suggest any difference in rates of postoperative HAEC between TERPT and LAPT procedures in our study 15% versus 25% respectively while incidence of HAEC ranged from 10% to 45% across studies; this compares to a reported incidence of 5–35% from previous studies.[19],[20] The variable rates of HAEC reported may relate to inconsistent definitions between studies. Kim et al[21]used a previously validated scoring system to assess severity and utilised a Delphi score to 'further secure uniformity' of the diagnosis of HAEC. Van de Ven et al[22] also used a Delphi score to diagnose HAEC. Neither Ishikawa et al[23] or Dahal et al[24] included definitions for the diagnosis of HAEC. In our study we found that there is significant difference between both groups in terms of faecal continence. The laparoscopic group had better outcomes regarding the degree of incontinence 70% of cases had normal bowel control compared to 50% in the trans anal group while in the other studies there was no difference in rates of faecal incontinence or constipation between TTERPT and LAPT groups. of crucial importance in the assessment of incontinence and constipation is an adequate period of follow-up to allow assessment of children at an age when continence should be expected and they have gained the necessary level of maturity and communication skills to report these outcomes. Follow-up durations were variable in the four studies that assessed these outcomes. In our study we reviewed only cases that was more than 3 years similar to Kim et al[21] who restricted their analysis to infants over 3 years of age and Ishikawa et al[23] included only infants with three or more years of postoperative follow-up. Van de Ven et al[22] included all infants with follow-up longer than 3 months. Dahal et al[24] did not set a minimum follow-up period, with an age range from 6 to 171 months. In all studies, the method used to assess faecal incontinence include an element of subjectivity. In our study we used the Cleveland Clinic Incontinence (CCI) scorewhile Kim et al[21] employed a previously published parental telephone interview survey of bowel function with investigators blinded to the patient's operative arm. Ishikawa et al[23] did not detail how follow-up data were obtained. There is some evidence that bowel function following definitive surgery for Hirschsprung's disease continues to improve until adolescence.[25] In addition, Dahal et al[24] acknowledge that the decision to utilise TTERPT or LAPT depended on results of barium enema, with longer segment disease more likely to be treated with a LAPT procedure. Reliance on a contrast enema to select patients for TTERPT introduces another potential difficulty for the surgeon as recent reports suggest that 10–31% of infants have no radiologically identifiable TZ and a further 8–38% of reported TZs are discordant with the confirmed pathological length of aganglionosis.[26]

Inflammatory Mechanism Evaluation between Application of Platelet-Rich Fibrin Membrane with Releasate and Amniotic Membrane in Rabbit Gingival Wound Healing

Ahmad Syaify[1], Paramitha Dewi Anggraini[2], Raudya Paramitha Adianti[2], Rezmelia Sari[1]

[1]Department of Periodontics, Faculty of Dentistry, [2]Faculty of Dentistry Universitas Gadjah Mada, Yogyakarta-Indonesia

Abstract

Background: Wound healing process is needed to restore the anatomical structure and physiological functions of the damaged tissue. The inflammatory phase in the wound healing process is characterized by the recruitment of neutrophil, macrophages and lymphocytes cells to the lesion site. Wound healing can be accelerated with PRF and amniotic membranes that can be used as dressings. These membranes have their respective strengths and weaknesses. This study aims tocomparethe inflammatory phasein the healing process of open wounds after the application of these two membranes.

Method: The subject of this study consisted of 36 males *Oryctolagus cuniculus* which, given a wound to the labial gingival of mandibular central incisors with deepitelization method. Subjects were divided into group I which applied to the PRF releasate membrane, group II, which applied with amniotic membrane and group III which not applied with both membranes. Three subjects were decapitated from each group on the 1st, 3 rd, 5th and 7th day. The number of neutrophils, macrophages and lymphocyte cells were observed with a light microscope equipped with Optilab Viewer software, then calculated and analyzed by two-way ANOVA test followed by the LSD Post Hoc test.

Results: The data of the average number of neutrophil, macrophage and lymphocyte were analyzed and shows the difference in the number of neutrophil between each group were significantly different ($p<0.05$). It also shows that the difference in the number of macrophages between the membrane groups and control group was significantly different ($p <0.05$), but the number of macrophages between group the membrane groups was not significantly different ($p >0.05$). Lastly, it shows the difference in the number of lymphocytes between each group were significantly different ($p <0.05$).

Conclusion: Growth factors contained in amniotic membrane and PRF membrane release can suppress inflammatory cells, so the inflammatory phase takes place faster than physiologically.

Keywords: *Neutrophils, macrophages, lymphocytes, PRF, releasate amniotic.*

Introduction

Wounds are the normal structure of the skin and its supporters that were damaged[1]. Surgery can cause damage to the epithelium which causes open wounds[2]. The presence of wounds will make the tissue respond by holding a wound healing process. Gingival wound healing has the same stage as skin wounds healing[3]. The wound healing process is needed to restore the anatomical structure and physiological functions of the damaged

tissue[4]. The wound healing process were hemostasis phase, inflammation phase, proliferation phase and maturation phase[5]. Migration of inflammatory cells such as neutrophils, macrophages and lymphocytes occurs in the inflammatory phase, where the cells have their respective roles in the wound healing process. Healing of open wounds is relatively slow due to epithelial loss, thus a dressing is usually addedto cover the wound so that postoperative complications do not occur while keeping the physiological healing process[6-7].

Biological membranes can be used as post-surgical dressing both in close and open wounds. Amniotic membranes have been shown to provide better wound healing after vestibuloplasty and gingival depigmentation. This membrane has the advantage of fulfilling ethical rules, is easy to obtain and contains factors that can accelerate wound healing. However, it has weakness in a clinical application such as thin and fragile so it is difficult to apply[8]. Another clinically proven membrane that can accelerate wound healing is the PRF membrane. This membrane comes from the patient's own blood and ashes relatively simple tools and materials [9]. PRF contains many growth factors that can help the wound healing process[10]. Growth factor contained by this membrane were such as PDGF, TGF-β and many more [11]. However, this membrane has limitations on the number obtained[12].

PRF membranes releasate and amniotic membranes have their advantages and disadvantages. Both membranes have also been shown to increase clinical gingival thickness. However, research on the differences in the inflammatory phase of wound healing after the application of these two membranes is still very limited. This study aims to determine the differences in the healing process of open wounds in the inflammatory phase after the application of these two membranes. Knowledge of this mechanism is expected to be useful as a material consideration for choosing the right dressing to be applied after surgery to open wounds.

Materials and Method

Materials: Oryctolagus cuniculus (LPPT-UGM, Indonesia), 4x4 mm amnion membrane (Batan Research Tissue Bank, Indonesia), ketamine hydrochloride (Kepro B. V, Holland) alcohol (One Med, Indonesia), 10% formalin buffer (Medis, Indonesia), xylene (Interchemie, Holland), paraffin (Medis, Indonesia), hematoxylin-eosin (HE, Merck, Germany), blue nylon no. 06 (Ailee, Korea), saline (Widathra Bhakti, Indonesia), centrifugator (MPW Med Instruments, Poland), light microscope (Nikon, Japan), platelet-rich fibrin (PRF) box (Osung, USA), dental loop, scalpel (Dentika, USA), needle holder (William, UK), eppendorf (Eppendorf, Germany), tweezers (dentika, USA), injection syringes (Terumo, Japan), glass slides and glass cover slides (Sigma-Aldrich, USA), microtoms (Rotary microtome, China), digital scales (Metler, USA), sonde, probes (William, UK), scissors (Dentika, USA), bent (Kurashiki, Japan), calipers (Tricle Brand, China), glass plate (Misumi, Japan), staining jar (Kilner, USA), waterbath (Huber, India), freezer (Hitachii, Japan).

Method

Preparation of experimental animals: The study was conducted using 36 Oryctolagus cuniculus rabbits divided into 3 groups, namely the application of membrane platelet-rich fibrin (PRF) with releasate amniotic membrane application group and negative or untreated control group. Each group consisted of 12 rabbits which were further divided into 4 groups according to decapitation days, namely days 1, 3, 5 and 7 after injury. The animal is trying to be adapted for 1 week before being given treatment.

Making platelet-rich fibrin (PRF) membranes and releasate: The blood used for making platelet-rich fibrin is taken from rabbit ear veins. Rabbit ear veins are dilated using xyelene. Taking 3 ml of blood is done using an injection syringe and inserted into eppendorf. The blood obtained was centrifuged at a speed of 2700 rpm for 12 minutes to form 3 layers, namely: plasma in the uppermost layer, platelet-rich fibrin in the middle layer and red blood cells in the lowest layer. Platelet-rich fibrin was taken using sterile tweezers and compressed using the PRF box for 5 minutes to form a stronger and more stable membrane and to provide a liquid or releasate by product. The PRF membrane is left submerged in releasate a few moments before it is applied.

Try Animal Injuries: The animals were anesthetized first by injecting ketamine hydrochloride and xyla fluids intramuscularly in the groin of the study subjects at a dose of 25 mg/KgBB. Injuries to the labial gingival area were performed using a deepitelization procedure in the labial gingiva of Oryctolagus cuniculus with a length of 4 mm and a width of 4 mm after anesthetized research subjects. The depth of the wound is controlled using a dental loop.

Giving treatment to experimental animals: Treatment in experimental animals is given according to the group of experimental animals. One layer of the amnion membrane with a width of one layer and releasate membrane PRF membrane was applied to the wound area of each group, then sutured using blue nylon no. 06. The negative control group was not applied to the amniotic membrane or PRF membrane with releasate.

Making histological preparations: Rabbits were decapitated on days 1, 3, 5 and 7. The tissue taken was fixed with a 10% formalin buffer solution, then histological preparations were made using hematoxylin-eosin staining technique.

Interpretation of results and data analysis: Calculation of the number of neutrophils, macrophages and lymphocytesin the connective tissue around the wound was carried out in 5 visual fields using a light microscope with 400x magnification. Observations were made by 3 observers with a double blind method. The results of the observation data are normality and homogeneity test, followed by two-way ANOVA and Post Hoc test using the LSD (Least Significant Difference).

Results

The number of neutrophils in the connective tissue around the wound were performed as seen in figure 1.

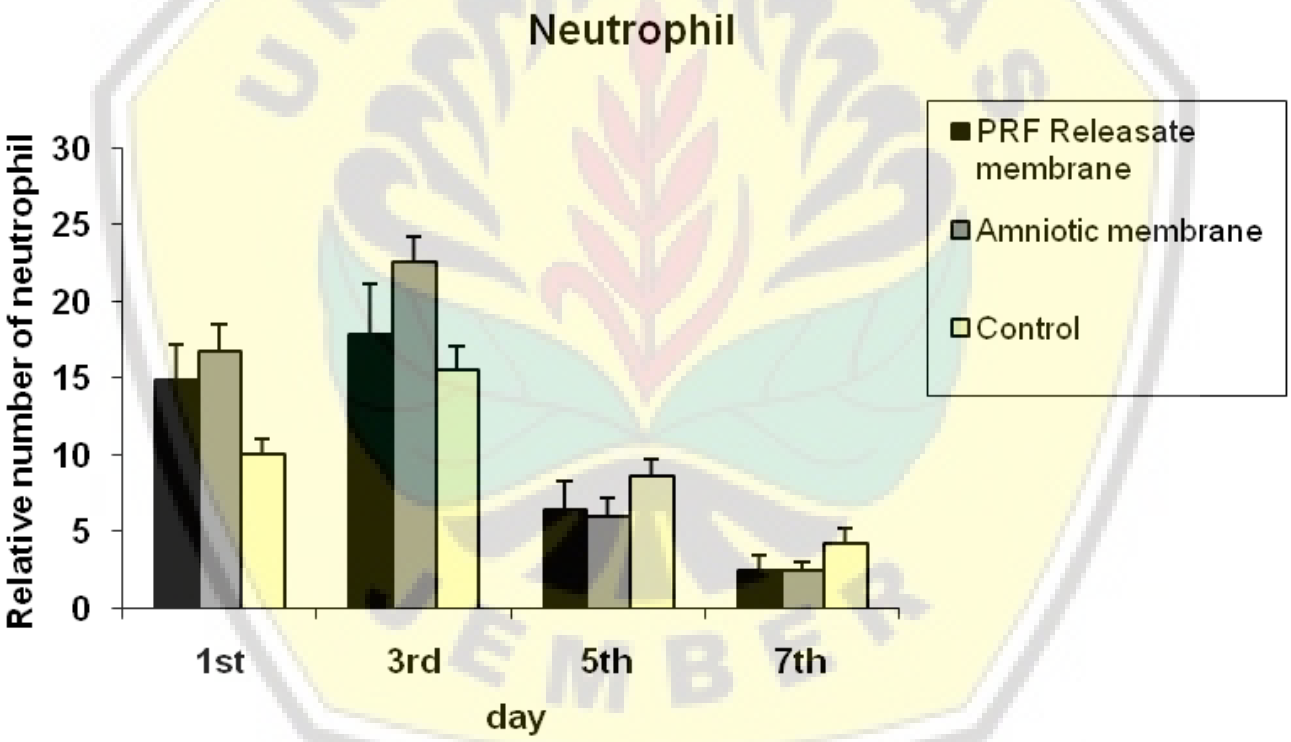

Figure 1: Relative number of neutrophils in the various days on PRF releasate membrane amniotic membrane and control (*, P<0.05, Anova two-way).

Based on figure 1, the number of neutrophil in each group increased from the first day to 3th day when they reached their peak with the number of neutrophil in group I and II were higher than group III and group I was lower than group II, then they were decreased on the 5th day until 7th day.

The relative numbers of macrophages in the connective tissue around the wound were confirmed as shown in figure 2.

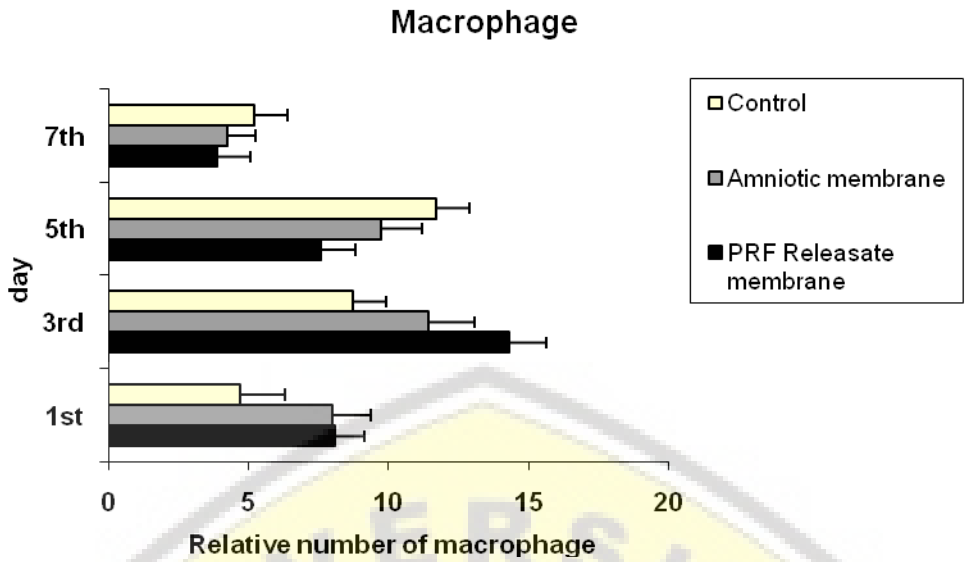

Figure 2. Relative number of macrophages in the various days on PRF releasate membrane amniotic membrane and control (*, P<0.05, Anova two-way).

Data in figure 2 shows the number of macrophages in group III increased from the 1st day and reached their peak on the 5th day, then decreased until 7th day, meanwhile group I and II increased from the 1st day and reached their peak on the 3 rd day then decreased until the 7th day. The group I and II reached the peak faster than the group III, with the number of macrophages in the group I was higher than group II on their peak day.

The relative numbers of lymphocytes in the connective tissue around the wound were confirmed as shown in figure 3. The number of lymphocytes in group III increased from the 1st day until the 7th day and reached their peak on last day, meanwhile group I and II increased from the 1st day and reached their peak on the 5th day then decreased until the 7th day. The group I and II reached the peak faster than the group III, with the number of macrophages in the group I was higher than group II on their peak day.

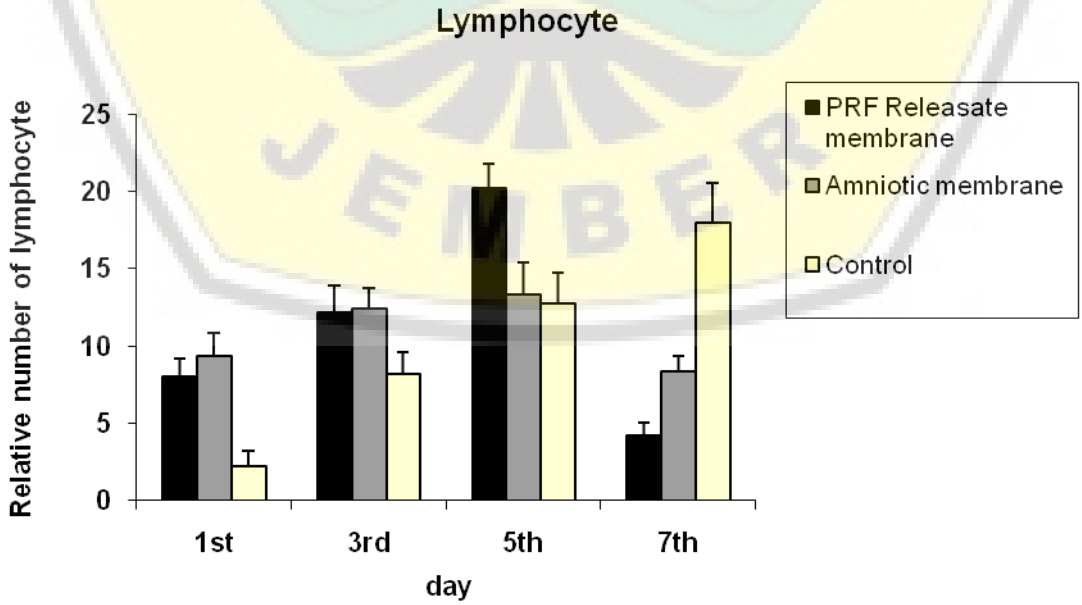

Figure 3. Relative number of lymphocytes in various days on PRF releasate membrane amniotic membrane and control. (*, P<0.05, Anova two-way).

The normality test with Saphiro Wilk and homogeneity test with Kolmogorov-Smirnov were examined. They showed the average number of neutrophil, macrophage and lymphocyte in each group was normally distributed and homogeneously. The Post Hoc LSD test shows the significant difference in the number of neutrophil and lymphocyte between each group ($p < 0.05$). Furthermore, the number of macrophages between the membrane groups and control group was significantly different ($p < 0.05$).

Discussion

PRF membrane releasateis a membrane from autologous blood that has been centrifuged without additional materials, so this membrane will be accepted by the body easier than amniotic membrane, while amniotic membrane is a membrane made of fluid from the deepest layer of the placenta and have functioned as an allograft material[8,13-14]. The body's acceptance to PRF membrane releasate is better than amniotic membrane, so it can suppress the inflammatory process. The inflammatory process that can be suppressed makes neutrophil counts in the PRF membrane releasate group lower than the amniotic membrane group on the 1st and 3rd days where these days are the time for neutrophils to work optimally. Neutrophils are the first inflammation cell that migrates to the injured area to do phagocytosis[4]. Some growth factors can trigger chemotactic and migration of neutrophils, so that at the beginning of the inflammatory phase neutrophil counts are higher in the treatment group than physiologically. In a previous study, it was known that the amniotic membrane contains TGF-β and b-FGF, while PRF membrane releasate contain TGF-β and VEGF[8, 15-17]. The workings of growth factors contained in these two membranes caused the difference in neutrophil counts. Neutrophils induce a rapid and sustained suppression of NF-κB signalling in the macrophage through a unique regulatory relationship[18]. Neutrophil counts in the PRF membrane releasate group show higher than the control group that neutrophils in the PRF membrane releasate group could call for more macrophage cells, whereas neutrophil counts in the PRF membrane releasate group is lower than in the amniotic membrane group showed that although fewer neutrophils appeared, but signaling to cell macrophages were more effective in the PRF membrane releasate group than in the amniotic membrane group.

Like neutrophils, macrophages that appear in the wound area are responsible for continuing phagocytosis and securing several growth factors activation of keratinocytes, fibroblasts and endothelium[4]. Recruitment of macrophages to the wound area can be triggered by growth factors, such as TGF-β and PDGF[4]. Amniotic membrane contains several growth factors and one of them is TGF-β[16]. PRF membrane themselves contains inflammatory mediators and growth factors, such as TGF-β, PDGF, VEGF and glycoproteins[15]. In addition, there is also a relationship between neutrophils and macrophages, so that on the 3 rd day the average number of macrophages from the PRF membrane releasate group and the amniotic membranes group reached their peak. This is probably due to the number of neutrophils in the membranes group are greater than the control group, so that the number of macrophage cells was more recruited to the wound area and neutrophils in the PRF membrane releasate group are more effective in giving signals to macrophage cells. Meanwhile the control group just reached its peak on the 5th day, whereas on the same day the number of macrophages in the PRF membrane releasate group and amniotic membranes had decreased. This shows that PRF membrane releasateis more effective in suppressing and accelerating inflammatory processes.

Lymphocytes which are the last inflammatory cells entering thewound area. Lymphocytes play a role in environmental regulation around lesions through the production of extracellular matrix scaffolding and collagen remodeling[3]. Lymphocytes also play a role in killing infected antigens and cells[19]. Lymphocytes reach the peak on the fifth day for the amniotic membrane and PRF membrane releasate group. This can occur because on the fifth day after injury the average number of macrophages has reached the peak. Macrophages themselves have a role in securing several cytokines such as IL-1β, IL-4 and IL-6[20]. IL-1β, IL-4 and IL-6 play a role in lymphocyte cell recruitment[21]. Some cytokines secreted by macrophages can support the proliferation and recruitment of lymphocytes in the lesion area so that when the number of macrophages increases, the number of cytokines also increases and results in increased lymphocyte counts and reaching the peak. On the seventh day, the mean number of lymphocytes showed a decrease in the PRF membrane releasate group and the amniotic membrane group, while in the control group it still increased and only reached its peak. A decrease in the number of lymphocytes on the seventh day is likely due to the apoptosis process. PRF membrane releasate

contain FGF and VEGF, which trigger the wound healing process to immediate reach the proliferation phase[22-24]. Inflammatory cells that have no role in the healing process of wounds, such as lymphocytes, will be eliminated by the process of apoptosis so that inflammation will soon end. So, the inflammatory process in the PRF membrane releasate group will end faster.

Conclusion

Growth factors contained in amniotic membrane and PRF membrane releasate can suppress inflammatory cells, so the inflammatory phase takes place faster than physiologically. This aims to prevent the delay in the wound healing process due to excessive inflammatory reactions.

Clinical Presentations and Surgical Management of Hepatic Hydatid Cyst: Ten Years' Experience in Three Teaching Hospitals in Egypt and Yemen

Ahmed A. Almalahy[1], Said H. Albahololi[1], Ahmed Nabil[2], Abdelkarem A.A. Mohamed[2], Haytham A. Alezzi[3]

[1]Associate Professor, [2]Lecturer, [3]Ass. Lecturer, General and Hepatopancreaticobiliary Surgery, Department of Surgery, Faculty of Medicine, Thamar University, Yemen

Abstract

Objective: The aim of this study is to review our ten years' experience regarding diagnosis, management of hepatic hydatid disease

Method: Retrospective review of all patients who underwent surgical treatment of hepatic hydatid cyst at Alwehdah Teaching hospital and Alkwait teaching hospital in Yemen and Kasralainy teaching hospital in Egypt from March 2008 till February 2019. One hundred and forty-five patients of either sex were included in the study. Reviewing their pre-operative clinical presentations, biochemical and radiological findings, surgical options, post-operative complications.

Results: A total of 145 patients were included, 102 (70.3%) men and 43 (29.7%) women with a mean age 40.75 years (range 24- 57 years). The presenting signs or symptoms leading to the diagnosis of hepatic hydatid cyst were: jaundice (10 cases, 6.9%), abdominal pain (28 cases, 19.3%), gastrointestinal discomfort of the upper abdomen (e.g. nausea, vomiting, distention, anorexia) (20 cases, 13.8%), palpable right hypochondrial mass (21 cases,14.5%). There were two mortalities (1.4%). Biliary fistula, pleural effusion and infection of the residual cavity were the major complications which represent (4.8%, 3.5%, 10.3%) respectively. Recurrence was seen in six patients (4.1%), three of them underwent resection, the other three were treated conservatively by long term albendazole.

Conclusion: Hydatid cyst of the liver is frequently asymptomatic and diagnosed incidentally during investigation for other abdominal pathology. Right hypochondrial pain and palpable mass were the most common presentations.

Pericystectomy and hepatic resection are associated with lower risk of recurrence but a higher rate of complications including biliary fistula and pleural effusion.

Keywords: *Hydatid disease, Pericystectomy, Echinococosis.*

Introduction

Hydatidosis is a zoonotic infection caused by a tapeworm. Of the various species, Echinococcus granulosus and E. multilocularis cause disease in humans. While dogs are the definitive hosts, humans are accidental intermediate hosts. Infection is acquired by ingestion of parasitic eggs released in the feces of the infected definitive host. On accidental ingestion by the

Tel: +201017818735

intermediate host, the eggs hatch and migrate to different tissues to form a multilayered cyst which is termed as primary echinococcosis.[1,2] Hydatid cysts are common in countries with agricultural areas,including North Africa, Spain and Portugal, Middle East, and Australia.[3-5]

Hydatid cysts can develop in any organ of the body, but are most frequently seen in the liver (60%-70%) and lungs (20%-30%).[6-8] The cysts grow about 1-30 mm in diameter yearly. Daughter cysts can develop inside the primary ones. The host isolates itself from the parasite by a connective tissue capsule (peri-cystic reaction).[9] The peri-cyst is important for surgical management, as leaving the peri-cyst in situ and removing the content of the cavity is a well documented and accepted surgical technique.[10]

Several modalities of treatments have been described to treat hydatid disease of the liver. Medical therapy alone is insufficient to cure the disease, although stabilization of disease have been reported with albendazole alone or in combination with other antiparasitic drugs like praziquantal.[11-13]

The physical characteristics and the location of the hydatid cysts, together with the general status of the patient, will guide the indications and type of surgery.[14,15]

We express our ten years' experience, reporting the various clinical presentations of the disease and evaluating the clinical outcome of patients who underwent surgical treatment of hepatic hydatid cyst.

Patients and Method

This retrospective analysis was conducted, reviewing all patients who underwent surgical treatment of liver Hydatid cyst at Alwehdah Teaching hospital and Alkwait teaching hospital in Yemen and Kasralainy teaching hospital in Egypt from March 2008 till February 2019. One hundred and forty-five patients were included in the study. These patients belonged to different parts of Yemen and Egypt. Patients with extra-abdominal involvement were excluded from the study. Similarly, patients with previous history of abdominal surgery, other hepato-billiary conditions like liver abscess, gallstones and obstructive jaundice were also excluded if these conditions were attributed to another cause. Cases of systemic illnesses like hypertension and diabetes mellitus were also not included.

All patients have been evaluated clinically, biochemically and radiologically before surgical intervention.

Pre-operative investigations included full blood counts, liver function tests, viral profile, blood sugar, blood urea, chest x-ray (P.A view), abdominal ultrasound, abdominal CT scan. Thoracic CT scan was performed in selected cases. All patients were admitted one day before surgery and one unit of cross matched blood was arranged in selected cases. An informed consent was taken in all cases.

Right subcostal incision was used in all cases for exposure of hydatid cyst of liver. For peripheral cysts radical excision was performed. The cyst was removed including the peri-cyst to avoid spillage of the hydatid fluid. For deep cysts, drainage with partial or total cystectomy was preferred.

The operative site was protected with gauzes soaked with H_2O_2 or povidone iodine. The residual cavity was soaked with a scolicidal agent: hypertonic saline solution (10-15%), H_2O_2 or povidone iodine. The peri-cyst was cleaned with removal of any daughter cysts found in the peri-cyst. Any communications with the biliary tree were ligated. Residual cavities were packed with omental flaps (Omentoplasty).

Any suspicion of intra-biliary rupture, the common bile duct was explored and intra-operative cholangiography was done.

A dose of albendazole 15 mg/kg/d for a period of few months was administered to all patients who had residual disease or had suspected peritoneal spillage.

Demographic data, clinical presentation, anatomical sites of the cysts, operative details, any reported postoperative complications and follow-up results were recorded and statistically analysed.

The statistical analysis relied on proportions and utilized common descriptive techniques. Summary statistics for these factors are presented as frequency and percentage. Follow-up was performed by clinic visits and ultrasonography was done when appropriate.

Results

A total of 145 patients were included, 102 (70.3%) men and 43 (29.7%) women with a mean age 40.75 years (range 24- 57 years). The presenting signs or symptoms leading to the diagnosis of liver hydatid cyst

are illustrated in table one. Jaundice was present in ten patients representing 6.9%. Abdominal pain represented 19.3%. The disease was diagnosed incidentally in 61 cases. Cysts were located on the right lobe in 93 patients (64.1%) and on the left lobe in 52 patients (35.9%) . Drainage with total or partial cystectomy was performed in 90 cases (62.1%), while a total peri-cystectomy was performed in 50 cases (34.5%) and partial hepatectomy was performed in 5 cases (3.45%).

The early postoperative course was totally uneventful in 115 (79.3%) patients. Overall complications were 20.7%. Bile leakage occurred in 7 patient (4.8%) and gradually subsided in three patients and ERCP with sphincterotomy was indicated in the remaining four patients with bile leakage. Suppuration and abscess formation in the residual cavity occurred in three patients (2.1%), who were reoperated for drainage of the abscess. One of the three patients developed septic shock and died. Five patients developed atelectasis and pleural effusion (3.5%) and were managed conservatively. Fifteen patients developed primary wound infections (10.3%) and were treated with drainage and antibiotics (Table 2). The mean hospital stay was 16.8 days.

There were two mortalities (1.4%). One died in the first week post operatively due to sepsis and the other one died three months post-operatively, due to acute hepatic failure, which was attributed to albendazole toxicity. Recurrence was seen in six patients (4.1%), three of them underwent resection, the other three were treated conservatively by long term albendazole.

Table (1): Clinical presentation of liver hydatidosis

Clinical presentation	Number (%)
Diagnosed incidentally	61(42.1%)
Abdominal pain	28 (19.3%)
Right hypochondrial mass	21(14.5%)
Gastrointestinal discomfort	20 (13.8%)
Jaundice	10(6.9%)
portal hypertension	5(3.4%)

Table (2): Complications following surgical treatment of liver hydatid cyst.

Complication	Number
Bile leakage	7 (4.8%)
Suppuration/residual cavity	3 (2.1%)
Atelectasis and pleural effusion	5 (3.5%)
primary wound infections	15 (10.3%)

Discussion

Hepatic hydatid cyst is still an endemic health problem in Yemen, as in some other areas of the world specially the Mediterranean area. Hepatic hydatidosis should be included in the differential diagnosis in case of incidental liver cyst.

Hydatid cyst of the liver usually remains asymptomatic and commonly diagnosed incidentally. The most common symptom is right upper quadrant and/ or epigastric pain.[16]

While Pain in the epigastrium and/or the right hypochondrium was the most common finding representing (19.3%) of patients in our study, the most common finding was a palpable mass which represented (14.5%) of the study.

The reported diagnostic sensitivity of ultrasound and CT scan is 96-96% and 100% respectively.[17,18] In the current study, the main diagnostic modalities employed were abdominal ultrasound and CT scans in all cases and had diagnostic accuracy of 100%.

The management of hepatic hydatid differs depending on different factors such as; the stage, localization, size, complications of the cysts, and the surgeon's preference. Surgical intervention remains the gold standard option.

The aim of surgical intervention is to inactivate the parasite, to drain the cystic fluid along with removal of the germinal layer, to prevent peritoneal implantation with scolices, to ligate any biliary communication and to manage any residual cavities, which can be done uneventfully in more than 85% of patients.[19]

There is, however, considerable disagreement about the preferred surgical technique. The major issue of debate is whether complete removal of the peri-cyst is necessary to cure the disease properly and thus whether conservative or radical procedures should be favored.[20,21]

The modalities of surgery including conservative and radical treatment can influence outcomes of the hydatid cyst of the liver.[22,23]

Some surgeons favour radical peri-cystectomy or hepatectomy, and some surgeons especially in endemic areas prefer more conservative approaches.[24-26] Two retrospective non-comparative studies concluded that radical treatment have decreased morbidity.[27,28] The

only prospective comparative study was reported by Tasev et al., who compared 102 patients undergoing radical surgery with 250 patients undergoing conservative surgical procedures.[29] They concluded that radical surgical procedures were associated with lower postoperative morbidity and mortality rates and a shorter postoperative hospital stay. However, these procedures were performed more frequently for hydatid cysts located in the left hepatic lobe. In another study, Birnermaun concluded that hepatic resection of the hydatid cyst did not increase surgical morbidity.[30]

Schmidt-Matthiesen et al. reported a comparative retrospective study and concluded that conservative procedures were preferable to peri-cystectomy which had the higher morbidity.[31] Other authors reported no difference between the two procedures.

We agreed with Dziri et al. that the radical procedures including peri-cystectomy and hepatic resection increase the operative risk of a benign disease.[16] However, these procedures were associated with a lower risk of recurrence. The conservative procedures were safer and easier to perform, although the morbidity was more prevalent.[16]

Baraket, O et al. stated that the post-operative overall morbidity rate was 26.6% in his study which include 120 patients,compared to our study in which the overall morbidity was 20.7%.[16]

The specific morbidity observed after surgical treatment of the hydatid cyst of the liver was variable. The most frequently encountered complications were postoperative biliary fistulas and abcess formation in the residual cavity.[16,33] In our study, biliary fistula, pleural effusion and infection of the residual cavity were the major complications representing (4.8%, 3.5%, 10.3%) respectively.

We agreed with Aktan and Yalin who reported in a prospective comparative nonrandomized study that included 70 patients that albendazole was effective in decreasing the viability of liver hydatid cysts when given for 3 weeks before operation, as albendazole has showed decreased incidence of recurrence in our study.[34]

Association between Obesity and Atopy in Children

Aidah Juliaty[1], Zubaidah Hehanussa[1], Dasril Daud[1]

[1]Department of Pediatrics, Faculty of Medicine, Hasanuddin University, Makassar, South Sulawesi, Indonesia

Abstract

Background: Increased incidence of atopy and obesity within the last few years poses a serious global health problem causing physical, social and economic burdens. The impact of obesity in the incidence of atopy is still controversial.

Objective: The study aims to determine the impact of obesity on the frequency of atopy in children.

Method: This study was a preliminary study with cross sectional design and conducted during June-August 2017 targeting the elementary, junior and high school students in the city of Makassar aged between 6 to 18 years old. Subjects who consented to participate in this study were asked to fill in the ISAAC questionnaire consisting of clinical manifestation and risk factors of atopic diseases. Total Ig E level was measured using ELISA method.

Results: A total of 120 subjects were enrolled and divided into two groups: 60 obese and 60 well-nourished children, following the criteria of Indonesian pediatrician society. Frequency of atopy in obese was 18 (30%) and 2 (3.3%) in well-nourished children. Statistical analysis using chi-square test revealed that the frequency of atopic was much higher in obese children $p < 0.05$; OR = 12.442; 95% CI 2.735-56.580.

Conclusion: Obesity strongly impacts the occurrence of atopy in children.

Keywords: *Atopy, obesity, well-nourished.*

Introduction

Obesity is defined as a state of comparison of body weight and height above the standard determined according to age and sex, due to excessive accumulation of body fat in adipose tissue so as to reach a level that can interfere with health. Obesity in children is functionally defined as an increase in body fat mass associated with high morbidity and mortality[1].

The prevalence of overweight and obesity in children worldwide increased from 4.2% in 1990 to 6.7% in 2010 and is expected to reach 9.1% in 2020. Based on basic health study data in 2013, there was a prevalence of obesity in (1) children under five in 2007, 2010 and 2013 based on body weight according to body height more than Z score using anthropometric standard of WHO 2005 were 12.2%, 14.0% and 11.9% and (2) children aged 5-12 years, 13-15 years and 16-18 years respectively 8.8%, 2.5% and 1.6% based on body mass index according to age more than Z score using WHO 2007 anthropometry standard[2].

Atopy is a genetic tendency to produce immunoglobulin E (Ig E) antibodies exposed to allergens[3]. A family epidemiology study supports the incidence of allergies, that genetic factors affect the atopic family. If one parent has an allergic disease, 25-40% of children will suffer from allergies. If both parents have allergies, the child's risk is 50-70% with

asthma (OR 1.5) or allergic rhinitis (OR 1.4)[4]. For cases of asthma, the WHO estimates occur in 5% -15% of the child population worldwide[3]. In Indonesia, the prevalence of allergic diseases that have been studied in some groups of society or hospitals shows variations, for example data from the RSCM Children's Allergy-Immunology Allergy Polyclinic of pediatric patients suffering from allergies about 2.4% in the form of cow's milk allergy[4].

Study by Musaad *et al*[5] showed that food sensitization affects the incidence of atopy. Continuous analysis of BMI with levels of immunoglobulin E (Ig E) supports the concept of weight gain in line with increased predisposition to atopic disease. Previous study by Chen *et al*[6] in China found no difference between the incidence of atopy in overweight or obese children with normal weight children. A study conducted by Visness *et al*[7] in the United States also examined the relationship of body weight with total serum Ig E, Ig E specific allergens atopy and allergic symptoms in children aged 2-19 years, while Eldin *et al*[3] correlate obesity and atopy, so did Apandi *et al*[4] in a study in Indonesia. it was found that there was a correlation between atopy and a history of family atopy in children. But in study conducted by Tin *et al*[8] in Hong Kongfound no correlation between obesity and atopy in children. So there was still controversy regarding the relationship between obesity and atopy in children, so It is important to know whether obesity is associated with atopic atopy in children in order to prevent complications that may occur in obese children. Based on this background, this study aimed to determine the relationship between obesity and the incidence of atopy in children.

Materials and Method

Design and Variable Study: This study is a preliminary study with a design cross sectional. The study variables consisted of: independent variables (obesity), dependent variables (atopy), intermediate variables (the biological process of forming immunoglobulin E (IgE) which is a sign of atopy in obese children), moderator variables (socioeconomic status, type of labor, number of siblings, duration of breastfeeding, mother's education level), random variables (genetics, stressors, gender, age, antigen exposure, air pollution, hygiene, and diit), and control variables (atopic family history and worm parasitic infection).

Location and Time of Study: The study was conducted in June - August 2017 for elementary, junior high and private high school students in Makassar. Examination of blood samples was carried out at the NECHRI laboratory of Hasanuddin University Makassar.

Population and Sample: The affordable population of this study is elementary, junior and senior high school students aged 6-18 years in the city of Makassar who come from private schools with middle and upper economic status based on criteria determined by the Makassar City Education Office. In this study, the selected elementary, junior high and high school were used as models to obtain the study population. Samples are all affordable populations that meet the study criteria.

Method of Collecting Data and Analysis: All patients who meet the requirements for history taking and physical examination are then recorded in the form provided previously . Weight measurement using a stepping scale that has been tested with accuracy of 0.1 kg. Height measurement using microtoise with accuracy of 0.1 cm. Nutritional status is determined based on body weight according to height according to NCHS standard. Then the calculation of BMI obtained from the results of body weight divided by height squared (Kg/m^2). Recording sample data using the ISAAC questionnaire and routine faecal examination to exclude worm infestations. Atopy determination was determined based on examination of total serum IgE. Obtained data were grouped based on purpose and type of data then analyzed using with univariate and bivariate analysis.

Results

During the study period, a total sample of 122 students was obtained, among the total sample there were 2 students whose blood samples were analyzed, so that the total sample analyzed was 120 students consisting of 60 obese students and 60 well-nourished students who met the inclusion criteria. Of the 120 study subjects consisted of 61 (50.8%) boys and 59 (49.2%) girls. The mean age of the study subjects was 12.62 years (Table 1).

Table 1. Characteristics of Study Samples

No.	Sample Characteristics	Obesity (n = 60)	Good Nutrition (n = 60)	P value
1.	**Gender**			
	Man	32(53.3%)	29(48.3%)	0.715 *

	Standard deviation	120.75	24.86	

*Uj Chi Square, **Mann-Whitney U test

In the normality test using the *Kolmogorov-Smirnov test* for total IgE levels, the data distribution was abnormal (<0.05), so the *Mann Whitney* test was used. The mean total IgE level in the obese group was 128.83 IU/mL, median value was 98.15 IU/mL and range was 71.19-761.01 IU/mL. Whereas in the good nutrition group, the mean value of total IgE levels was 96.00 IU/mL, the median value was 92.11 with a range of 12.31-181.23 IU/mL. *Mann Whitney* test results showed that there were significant differences between the two groups with $p = 0.005$ ($p < 0.01$) (Table 2).

Table 2: Average value of total IgE level in obese group and good nourished group

Total IgE (IU/mL)	Obese Group (n=60)	Good Nourished (n=60)
Mean	128.83	96.00
Median	98.15	92.11
Standard deviation	120.75	24.86
Minimum–maximum	71.19 – 761.01	12.31 – 181.23

Mann Whitney Test, p= 0.005 (p<0.05).

Chi-square test showed no significant difference in atopy frequency based on sex (p = 1.000), type of delivery, with p = 1.000 (p > 0.05), level of mother's education (p = 0.09), period of breast feeding (p = 0.876), economic status (p = 0.499) and number of siblings (p = 0.08).Large analysis of risk for atopy showed that sex, type of delivery, level of mother's education, period of breastfeeding, economic status, and number of siblings was not a risk or protective factor for atopy. Crude Odds Ratio (COR) of sex, type of delivery, economic status, and number of siblings were 0.961(0.368-2.510), 1.43 (0.166-12.309), 0.651 (0.190-2.234), and 2.897 (0.903-9.22) respectively.

Meanwhile, analysis of the association between obesity and atopy showed based on *chi square* test showed a significant differences between the obesity and good nourished groups with p = 0.000. The odds ratio (OR) = 12.442 (95% Cl 2.735-56.480), which means that children with obesity were 12.43 times riskier to have atopy compared to good-nourished children. (Table 3).

Table 3. Frequency Analysis Based on Sex, Type of Labor, Mother's Education Level, Length of Mother's Milk, Economic Status, Number of Siblings, and Nutrition Status

	Atopy		Total	P	OR (95% CI)
	Yes	No			
Sex					
Man	10 (16.4%)	51 (83.6%)	61 (100%)	1.000 *	0.961 (0,36 - 2,51)

Discussion

In this study, the frequency of atopy in boys compared to girls was not significant with p = 1.000. This is similar to what was found by Leung *et al*[9] in Hong Kong who found no significant difference between sex with atopy. This is different from the study by Visness*et al*[7] which found that girls have a higher risk of atopy. It means that sex does not bias in the analysis between atopy and non-atopic groups.

This study found that obesity affects the incidence of atopy. The same result was obtained by Visness *et al*[7] which stated that total IgE levels in children with obesity was higher than good nourished children. Musaad *et al*[5] found that food sensitization affects the incidence of atopy. Continuous analysis of BMI with levels of IgE supports the concept of weight gain is positive correlate with increased predisposition of atopic disease. Eldin *et al*[3] who examined the association between obesity and atopy in children aged 4-18, and Setiabudiawan *et al*[10]who analysed the correlation between total serum IgE levels and obesity in children aged 6 - 11 years had significantly similar results, obese children with atopy had higher total IgEserum levels.

IgE levels are strongly influenced by genetic factors, age and race factors. Apandi *et al*[4] in Indonesia found that there was a correlation between atopy and a history of family atopy in children. Different results were discovered by Tin *et al*[8] who found no correlation between the two, but this study was lackingin the data of environmental factors related to the onset of atopy.

Previous studies suggested that it is possible that obesity can cause atopy or inflammation and there are several factors that predispose to both obesity and atopy. Leptin is an important regulator that reflects the mass of adipose tissue, which is comparable in number with fat mass. Triglycerides are a type of lipid in the blood whose numbers increase in the condition of diet-induced obesity[11]. Triglycerides contained in the blood are thought to inhibit leptin from entering the blood brain barrier.

In obesity, there is resistance to the leptin receptor which will affect the balance of Th1 and Th2. Resistance to leptin receptors in obese children occurs one of them is due to interference with leptin signaling in leptin receptors. In addition to disorders of leptin signaling in obese children, leptin receptors, receptor defects, reduced number of leptin receptors and impaired leptin transport into the central nervous system were also found. Leptin resistance will cause increased production of Th2 cytokines, such as IL-4, IL-5, and IL13. IL-4 secretion will cause the *switching* process of B lymphocytes which then produce specific IgE, which is an atopic marker[3,4]

In this study, there was no significant difference in the relationship between obesity with several factors including: sex, economic status, mother's education level, period of breastfeeding, and the number of siblings, becausethey were excluded. Genetic factors for atopy are very difficult to identify; but genetic polymorphism in the β IgE (Fc RI-B) receptor chain is located on chromosome 11q12-13, as well as class II HLA involvement. This indicates that the production of specific IgE associated with the HLA class II and genetic polymorphisms in the cytokines IL-4 which causes the formation of IgEspeccific[4]. This study concluded that the frequency of atopy incidence in children with obesity was higher (30%) than good nourished children (3.3%).

Conflict of Interest: No Potential conflict of interest relevant to be declared

Source of Funding: This study was conducted with self funding, no external funding sources for this study.

Ethical Clearance: The study has been permitted and

acknowledged by Hasanuddin University Ethic Medical Committee. Before each interview, each participant was given written information on the study. Each participant was also informed that his or her participant was voluntary. Before each interview, we emphasized the importance of maintaining confidentiality in relation to patient cases. All participants provided written consent to participate in this study.

Abstract

Background: Many studies have demonstrated that iron, folate, Serum ferritin, Total iron binding capacity (TIBC), Unsaturated Iron Binding Capacity (UIBC), vitamin B1, B2, B6, B12 deficiencies occur in Recurrent aphthous stomatitis (RAS. The aim of this study was to evaluate serum level of vitamin B12, folate, ferritin, iron binding capacity, unsaturated iron binding capacity among patients with RAS.

Materials and Method: A cross sectional study carried out in Al-Sulaimani teaching center of dermatology for period from 1st of March to the end of June, 2014 on 30RAS patients and 30 healthy controls. Data were collected were demographic information and results of haematinic investigations for selected patients. Data were analyzed using software SPSS program version 17.

Findings: Mean age of RAS patients was 40±14 years. Male and female patients were equally distributed. A significant difference was observed between patients and controls in family history of RAS ($p<0.001$). Mean B12 level of RAS patients was

190.6±80.3Pgm/ml, there was a significant difference in means of B12 between patients and controls ($p=0.009$). Mean serum folate level of the patients was 10.2±4.6 ngm/ml, there was a significant difference in means of serum folate between patients and controls ($p=0.01$). Meanserum iron level was 55.5±18.8 µg/dl a significant difference was observed between patients and controls in means of serum iron ($p<0.001$). No significant difference was observed between patients and controls in means of ferritin, TIBC and UIBC ($p>0.05$).

Conclusions: Family history, serum B12 level and serum iron are associated with RAS patients. It is important to investigate vitamin B12, folate and iron deficiencies in patients with RAS.

Keywords: *Aphthous, stomatitis, vitamines anemia.*

Introduction

Recurrent aphthous stomatitis (RAS) is defined as the presence of recurring ulcers confined to the oral mucosa[(1)]. RAS is characterized by recurrent, small, round, or ovoid ulcers often multiple with circumscribed margins, erythematous haloes and yellow or grey floors that present first in childhood or adolescence[(2)]. RAS occurs worldwide and are reported on every populated continent. RAS affects 20% of the population, with the incidence rising to more than 50% in certain groups of students in professional schools. Children from high socioeconomic groups may be affected more than those from low socioeconomic groups[(3)].

The etiology of recurrent aphthousstomatitisis

Corresponding Author:
Amir H.K. Kareem

e-mail: amirkareem@yahoo.com
Mobile: +9647705330777

still not under stood although many predisposing and precipitating factors have been described: trauma, stress, changes in the immune system, sensitivity to certain types of food, or ingested substances such as preservative agents or the substances like cinnamaldehydeorsodiumlauryl sulfate present in some toothpastes and iron, zinc, folate, vitamin B1, B2, B6, B12 deficiencies [4].

The main pathogenetic event is the inflammatory response with production of inflammatory cytokines, prostaglandin E2 and nitric oxide. The pathophysiology of aphthous ulcers is not clearly understood. Alteration of local cell mediated immunity is often encountered in patients with recurrent aphthous ulcer. Systemic T- and B-cell responses have also been reported as altered in patients with RAU[5]. Three clinical presentations within recurrent aphthous ulcer has been identified which are : Aphthous ulcer minor (synonym Mikulicz ulcers) (Mi AU); Aphthous ulcer major; and Herpetiform recurrent aphthous ulcer[6].

Discussion

RAs is a common presentation for both dermatology and genral practice clinics. Considerable proportion of people are unware of the method to reduce its prevalence. The demographic characteristics of our sample are consistent with results Fariba I, et al study in Iran (2005) that reported equal male to female ratio and mean age of patient was 30.5 years [14]. Our findings are also close to results of Tarakji B, et al study in Saudi Arabia (2012)[15] that reported prevalent age group of AS patients 30-39 years but males were more than females, on other hand, these findings are inconsistent with Abdullah MJ, et al study in Al-Sulimaniya (2013)[16] that reported main age group for RAS was 20-29 years and females more than females.

The prevalence of RAS among adults was significantly higher than that (17.9%) reported in US adult population aged over 17 years [17]. More than half of the RAS patients had positive family history. Reports of family history were frequent in this population (53.3%) as observed in the previous literatures [18, 19] supporting a genetic involvement in the etiology of RAS.

The present study revealed a significant decrease in mean of serum B12 among RAS patients (p=0.009). Mean of serum B12 for patients was 190.5±80.3Pgm/ml and that for controls was 240±60.8Pgm/ml. Volkov I, et al study in USA (2009)[20] concluded that vitamin B12 treatment, which is simple, inexpensive and low-risk, seems to be effective for patients suffering from RAS, regardless of the serum vitamin B12 level.

Burgan SZ, et al study in Jordan (2005)[21] reported that Patients with recurrent aphthous stomatitis have more hematinic deficiencies, particularly vitamin B12 deficiency, compared with controls. Correction of these hematinic deficiencies could help in the management of the disease. Liu HL, et al study in Southern Korea (2013) [22] resulted vitamin B12 therapy to have a statistically significant benefiton pain relief among recurrent aphthous stomatitis sufferers.

Binary logistic regression analysis revealed that the main risk factors for RAS in this study were family history (p=0.002), serum B12 (p=0.003) and serum iron (p=0.008). A genetic predisposition for the development of aphthous ulcer is strongly suggested as about 40% of patients have a family history and these individuals develop ulcers earlier and are of more severe nature. Various associations with HLA antigens and RAS have been reported. These associations vary with specific racial and ethnic origins [18].

It has long been thought that iron, folate and vitamin B12 deficienciesplay an important role in RAS, but some controversy does exist. Wray D, et al [23] reported that hematinic deficiencies affect up to 21% of adult patients with RAS and when they replaced the deficient element, 59% of the patients showed resolution of RAS and 28% showed significant improvement. However, other studies have shown that patients with RAS and controls had comparable serum iron, folate or vitamin B12[24, 25].

Conclusion

In conclusion, family history, serum B12 level and serum iron are associated with RAS patients. It is important to investigate vitamin B12, folate and iron deficiencies in patients with RAS.

Food Security and Coping Strategy among Household in Food Insecure Area

Annis Catur Adi[1], Rian Diana[2], Dini Ririn Andrias[3]

[1]Lecturer in Department of Health Nutrition, Faculty of Public Health, Universitas Airlangga, Campus C Mulyorejo, Surabaya-Indonesia

Abstract

Introduction: Food security is a problem in developing countries. Food insecure household usually adopted coping strategies. Therefore, this study aim to analyse the correlation of household food security and coping strategies in food insecure area.

Method: This cross sectional study were done in Bangkalan District, Madura Island, Indonesia which included 200 households having children under five. A structured questionnaire was used to collect the household characteristics and coping strategies. The food security status was assessed by Food Insecurity Experience Scale (FIES). Correlation data was analysed by Chi-square test.

Results: The prevalence of household food insecure was 67.5%. As much as 41% was mildly food insecure, 20.5% moderately food insecure and 6% severly food insecure. The popular coping strategy was borrowing food/money from friends and relatives (34.5%) and eating less-preferred foods (21.5%). The household coping strategy was correlated with household food security status ($p<0.001$). The more severe food insecurity status the higher proportion of coping strategies adopted.

Conclusion: High prevalent of food insecure household in food insecure area. Social capital become an important factor in combating food insecurity. Targeted activities or beneficials are recommended in order to alleviate the burden of food insecurity in this area.

Keywords: *Food security, coping strategy, household food insecurity, FIES.*

Introduction

Food security exists when all people have access to sufficient, safe and nutritious food that meets dietary needs and food preferences[1]. Food insecurity is a problem in developing countries particularly in an archipelago country like Indonesia. In general, there were 9.76% of households with moderate and severe food insecurity in Indonesia[2]. Nonetheless, this proportion was quite diverse among province and higher in isolated Island[3].

Food insecure households adopted coping strategies to minimize the effect of food shortages. Various coping strategies were done by the households to overcome the food insecurity condition by doing food compromisation (quantity and quality of food) and or financial coping strategies[4)] such as borrowing money, selling assets or crop and looking for a new jobs[5)]. Study in the poorest area of South Africa found that food coping strategies done by the households in the area had a long-term detrimental effects[5)].

Several studies have explore coping strategies[6)], food security asessment[7)] and it's determinant[8)9)10)] and its association with coping strategies[4)5)]. Nonetheless, household food security assessment using Food

insecurity experienced scale (FIES) is new in Indonesia and it was used to assess the household food security officially in 2017. Limited information about household food security and it's relationship with food coping strategies in food insecure area. Therefore, this study aim to analyse the correlation of household food security and coping strategies in food insecure area.

Method

This cross sectional study were done in Bangkalan District, Madura Island, Indonesia. Bangkalan district was purposively selected as a study site because it was a food insecure area with high prevalence of malnourished children. Data were collected from 200 households having children under five. A structured questionnaire was used to collect the data. Household characteristics, food security status in the last 12 months and coping strategies in the last four week period were asked to each household. The food security status was assessed by Food Insecurity Experience Scale (FIES)[11]. There were 8 FIES questions which explain 3 domains (uncertainty and worry about food, inadequate food quality and insufficient food quantity). Food security status categorized into food secure when the household did not experience one of the 8 items of FIES, mild food insecurity (experience condition 1-3), moderate food security (experience condition 4-6) and severe food insecurity (experience condition 7-8).

Five standard coping strategies were generated from the reduced coping strategy index(CSI)[12] and were asked to the respondents. This five questions were the five most common behaviors changes in response to food shortages. This five coping strategies can describe the dietary changes, increase in short-term household food availability and rationing strategies or managing the shortfall.

Correlation were analyzed by chi-quare test. This study received ethical clearance from ethical committee of Faculty of Public Health, Universitas Airlangga (No 561/EA/KEPK/2018).

Results

Table 1 showed that most of the households have less than 6 family member, 39% were small household (≤4 family member) and 37% were medium household (5-6 family member). Majority of the hus Bands and wives education level were less than 9 years (basic education). Half of them were graduated from elementary school. Only 12% hus Bands and 9.5% wives were graduated from higher education such as diploma or under-graduated school.

Based on FIES (Table 1), Most of the households (67.5%) were food insecure. Only 32.5% were identified as food secure. Greater proportion of household experienced mild food insecurity (41%) than moderate (20.5) and severe (6%). From 8 questions of FIES (Table 2), it can be seen that more than half household (61.5%) were worried anxious and concerned that they might not having enough food or run out of food because of lack of money or other resources. Almost half of the household (44%) were worried that they not able to eat nutritious and healthy food. Moreover, 19.5% of the household experienced insufficiency of diet quantity and 29% having low diet quality. Less than 10% of the household felt hungry and went without eating for a whole day.

Discussion

High proportion of food insecure household (67.5%) was found in this study, 41.0% of them were mildly food insecure. This finding showed almost half of the households experienced the anxiety or worry about food and inadequate food quality. Inadequacy of food quantity was also experienced by the household particularly eating less than they should be and ran out of food. The food insecure proportion of this study was lower than studies in isolated island in Madura [3] but higher than African countries [7] and poorest states in Brazil [13]. Nonetheless, this differences can be happen due to different geographical condition and the instrument used in assessing the food security status. The instrument to assess food security in this study was using FIES. This FIES has been validated in many countries including Indonesia[7]. Since 2017, FIES also had been entered in national socio-economic survey Indonesia which conducted quarterly. High burden of food insecurity can affect the nutrition security [14][15]. Indonesian nutrition surveillance showed that Madura Island particularly Bangkalan District have a high prevalence of malnutrition among children under five [16].

Households respond to food insecurity differently. Many households using multiple coping strategies to cope their food shortage. Increasing short-term food availability and dietary changes (quality and quantity) were the most common coping mechanism. Borrowing food/money from friends and relatives was more popular than changing the dietary habit in this area. Madurese

has a strong kinship. Neighboring members know each other and most of them have kinship links and maintain exchange relationship. Nearby neighbours are the first focus of solidarity [17].

The household coping strategy was correlated with household food security status ($p<0.001$). The more severe food insecurity status the higher proportion of coping strategies adopted. Coping strategies not only adopted by the food insecure household but also the food secure ones. Although not many food secure households doing it. Coping mechanism that were done by the household when it continue and done in long term can be an adaptive mechanism therefore can endanger the nutrition security.

Conclusions

High prevalence of food insecurity was found in this study. Coping strategies commonly adopted was borrowing food/money from friends and relatives. The more severe food insecurity status the higher proportion of coping strategies adopted.

Conflict of Interest: The authors have no conflicts of interest associated with the material presented in this paper.

Source of Funding: This research was supported by Universitas Airlangga grant no 886/UN/2018

Ethical Clearance: This study received ethical clearance from ethical committee of Faculty of Public Health, Universitas Airlangga (No 561/EA/KEPK/2018).

Recommendation: Targeted beneficials and activities in improving food security are recommended in order to alleviate the burden of food insecurity in this area. Social capital such as strong kinship among Madurese need to be preserved and can have a potential role in building food secure household.

Health Care Seeking Behavior of People with Tuberculosis to Improve Cases Finding on Private Practitioners in Surabaya, East Java, Indonesia

Chatarina Umbul Wahyuni[1], I Wayan Gede Artawan Eka Putra[1,2], Hari Basuki Notobroto[1]

[1]Faculty of Public Health, [2]School of Public Health, Faculty of Medicine, Universitas Udayana

Abstract

Introduction: Indonesia is the third burden country of Tuberculosis (TB). Cases finding acceleration is an important strategy for TB elimination. This study aimed to describe health care seeking behavior of PWTB and identify the factors associated to patient delay on seeking care for TB.

Method: This was a cross sectional study in Surabaya City, East Java, Indonesia from April-June 2018. All PWTB aged >15 years old who diagnosed from January until May 2018 were selected for interview. Health care seeking behavior including type of health facilities visited previously and patient delay from first onsettoseeking care for TB. Data were collected through face to face interview using a structured questionnaire.

Results: One hundred and sixty people with TB (PWTB) were enrolled in this study. We found 40(25.0%) PWTB previously seeking care to private practitioners (PPs), 75(46.9%) to PHC/PHC and 45(28.1%) self-treatment. The median time of patient delaywere 30 days,91(56.9%) were ≤30 daysand 69 (43.1%) were >30days (delay). PWTB who previously seeking care to PPsis higher risk to delay compare to PHC/ hospitals (AOR=4.341; 95%CI:1.491-12.637). The others factors of patient delay were perceived barrier about diagnostic cost (AOR=8.384; 95%CI: 1.812-38.802) and fever (AOR=2.435;95%CI: 1.042-5.693). Hence, the factors that prevent the diagnostic delay were have TB family history (AOR=0.294; 95%CI: 0.111-0.778), knowledge aboutTB is a curable disease (AOR=0.133; 95%CI: 0.041-0.430) and duration of the therapy (AOR=0.022; 95%CI: 0.002-0.287).

Conclusions: The patient delay among who previously come to PPs and self-treatment need to be shorten. PPM program should be provided capacity building to PPs and health providers. They should educate the presumptive TB particularly about the variation of TB symptoms, the cost and detail of TB examinations and treatment to encourage them to follow TB examinations.

Keywords: *Tuberculosis, health care seeking behavior, patient delay, cases finding, private practitioners.*

Introduction

Indonesia is the third Tuberculosis (TB) burden country with 842,000 estimated incidence. The National Tuberculosis Control Program (NTP) targeting TB Elimination in 2030. One of important strategy is achieve the optimal cases finding and cure all notified. The TB cases finding in 2017 is relatively low, the cases detection rate (CDR) were 42.4%. The CDR already increasing compare to 35.8% in 2016, but still far from the target 70%[1–3]. A bold strategy is needed to accelerate the cases finding and support the TB Elimination.

The TB prevalence survey 2013-2014 in Indonesia shows 36.5% of people who previously TB seeking

Corresponding Author:
Chatarina Umbul Wahyuni
Faculty of Public Health, Universitas Airlangga
e-mail: chatrin03@yahoo.com

treatment in private sectors (PPs and private clinic)[4]. Private practitioners (PPs) have important role on TB cases finding. One of the focuson Indonesia TB elimination roadmap 2030 is strengthening public-private mix (PPM). The strengthening of PPM were implemented at the first milestone (2018-2021)[5,6]. The engagement of PPs in PPM scheme as an indicator on the TB implementation program in each district/city [7].

The PPM program in Surabaya already initiated in 2015. The collaboration begun with dissemination and workshop regarding TB program. The evaluation shows the contribution of PPs in Surabaya city to PWTB finding in 2017 were very low, only1.4% among all cases[8]. Study among PPs already done and continued by a modified collaboration. Improvement on recording and reporting system of PWTB who refer from PPs also already done. Based on the latest evaluation in 2018, the contribution of PPs on TB cases finding were still low 4.5%[8].

The most barrier from presumptive/PWTB is about the health seeking care behavior. The delay on seeking care will lead to the delay on diagnosis and treatment. This is a major barrier on TB cases finding and prevention [9]. Therefore a study to understand the health seeking care behavior before PWTB came to diagnosis confirmation and factor to the diagnosis delay is important to accelerate and improve the cases finding in all health facilities especially in PPM program. This study aimed to describe health care seeking behavior of PWTB before diagnosed and identify the factors associated to patient delay.

Method

Design: This was an operational research to support TB control program performance on expanding the cases finding in private practitioners. The design is cross-sectional study.

Study Settings: Surabaya city is the second biggest city in Indonesia with population in 2017 was 3.057.766 persons. TB control program in Surabaya City implement the national TB control guidelines that adopted based on WHO guidelines. The cases notification rate in 2017 was 225.7 per 100.000 population, still not yet reach target 257 per 100.000 population. The success rate for TB treatment are increasing from 83% to 87% in 2017 or 3% to target 90%[8].

Study population and sample: Study population are all adult pulmonary PWTB (aged >15 years old)in Surabaya City. Sample were selected from pulmonary PWTB who diagnosed from January until May 2018 at PHC in East Surabaya. All sample selected were invited to participate. Pulmonary TB was diagnosed according to the criteria established in the Indonesian Guidelines for Tuberculosis[7]. PWTB who refused signing the inform consent form were excluded from the study.

Variables and the operational definition: Health seeking care behaviors were including the type of health facilities visited before for seeking care for TB and the duration of time (in days) between the first onsets of TB symptoms until seeking care for TB (patient delay). The duration was divided into ≤ 30 days and > 30 days (delay). The factors of patient delay including characteristics (individual and clinical characteristic) knowledge and perceived about TB. Individual characteristics were age, sex, education, occupation and health insurance status. Clinical characteristics were TB family history and TB symptoms. Knowledge were knowledge about mode of transmission, mode of prevention, TB symptoms, TB examination, TB is a curable disease and duration of TB therapy. Perceived were perceived about the severity of TB, benefit of TB examination, barrier on TB diagnostic costs and barrier on distance to PHC.

Data collection and analysis: Data were collected through face to face interview using a structured questionnaire. The questionnaire were tested for validity and reliability before used for data collection. We trained 12 interviewers to perform the data collection. They trained to approach PWTB, make an appointment and interview using the structured questionnaire at the PWTB's home. Descriptive analysis presenting relative frequency, mean and median in cross tabulation. Binary logistic regression was perform to identify association between the subject characteristics and factors with the patient delay. Adjusted Odds Ratio (AOR) with the 95% confident interval (CI) were presented for the strength and direction of the association.

Ethic Approval: The ethical clearance was obtained from The Ethical Committee of Faculty of Public Health, Universitas Airlangga.

Results

One hundred and sixty people with TB (PWTB) were enrolled in this study. The average of age was 43.2 years old, 90(56.3%) were female, 88(55.0%) were senior high school or higher education level and 143(89.38%)

have health insurance. We found 40(25.0%) PWTB previously seeking treatment to PPs, 75(46.9%) to hospitals/PHC and 45(28.1%) to alternative medicine.

The median patient delay were 30 days,91(56.9%) were ≤30 days and 69 (43.1%) were >30days (delay). PWTB who previously seeking care to PPsis higher risk to delay compare to who directly seeking treatment to PHC/hospitals (AOR=4.341; 95%CI: 1.491-12.637). The others factors of patient delay were perceived barrier about diagnostic cost (AOR=8.384; 95%CI: 1.812-38.802) and fever (AOR=2.435; 95%CI: 1.042-5.693). Hence, the factors that prevent the patient delay were have TB family history (AOR=0.294; 95%CI: 0.111-0.778), knowledge aboutTB is a curable disease (AOR=0.133; 95% CI: 0.041-0.430) and duration of the therapy (AOR=0.022; 95%CI: 0.002-0.287).

Table 1: The Characteristics, Tuberculosis Symptoms and Diagnosis Duration by Type of Health Care Seeking Behavior Before Notified

Variables	Type of Health Care Seeking Before Notified			
	PHC/Hospital (n=75)	Private practitioner (n=40)	Self-treatment (n=45)	Total (n=160)
Age	41.4±15.0	43.4±17.3	46.3±16.0	43.2±19.9
≤ 40 years old	37(49.3)	19(47.5)	16(35.6)	72(45.0)

Discussion

This study found 25% of PWTB previously seeking care to PPs. Median patient delay in overall found 30 days. PWTB who previously seeking care to PPs and self-treatment have longer median patient delay until 60 days compare to who came to PHC were 30 days. Prolonged median patient delay may cause by health seeking care behavior from one PPs to other PPs for second opinion. Among self-treatment, they try several time with symptomatic drugs from alternative medicine and/or modern medicine that freely saleat drug store [10]. This result supported by the multivariable analysis that found the probability of PWTB delay on diagnostic is 4.3 time compare to who directly come to PHC/hospitals. The results indicate a problem on their acceptability and awareness regarding the disease. The delay also associated to the physiological proses particularly the self-acceptance proses[11].

This study succeeded identify the factors of patient delay. Beside the previous seeking care to PPs, the others factors encourage the diagnostic delay were PWTB with fever, cough and have perceived barrier about diagnostic cost. PWTB Fever is a common symptoms for many infection diseases. The PWTB who with fever and cough will belief the symptoms just a common infectious disease. The possibility for TB will be last until the come to PHC. This result is concordance compare to others study that found majority of PWTB with cough were having significant patient delay. The main reasons behind that were self-medication and having perception that symptoms are not severe and will disappear gradually[12]. Education should focus to explain about the variation of TB symptoms. Explanation about risk of TB in Indonesia as the third burden country are important. The possibility for TB should be thinking if the symptoms were occurred.

PWTB who perceived that following TB examinations will spend additional costs will tend to delayed on accessing PHC. They may perceived about cost of the examinations, transportation and income lost during the process. Perceived barriers about diagnostic cost in an individual-level barriers[13]. This perceived should be tackle by explaining about the benefit of TB

early detection. Education should explain that early detection have important beneficiary such as perfect treatment outcome and prevent transmission to others around.

Factors that prevent the diagnostic delay were have family history of TB, knowledge about TB is curable disease and duration of TB treatment. Presumptive/ PWTB who have TB family history already exposed more information regarding TB previously have higher awareness regarding TB. Knowledge about TB is a curable disease and duration of TB treatment will increase their understanding, belief and confidence for following TB examination. Knowledge is an established factor of patient delay and health seeking care behavior based on many studies previously[9,11]

These study findings have important policy implications. First, the study shows theimportant of motivation to presumptive and PWTB who previously came to PPs. Second, a comprehensive education should provide to presumptive TB to accept recommendation for further TB examination in PHC. The comprehensive education should consider cognitive and psychological aspects. The collaboration with PPS in PPM scheme should provide capacity building for PPs how to educate,motivate and encourage presumptive TB Come to PHC immediately.

Conclusions

The patient delay should be shorten particularly among who previously come to PPs and self-treatment. PPM program should provide capacity building to PPs and others health provider regarding how to educate, motivate and encourage presumptive/PWTB for TB early detection. They should educate the presumptive and PWTB particularly about the variation of TB symptoms, the cost and detail of TB examinations and treatment to encourage them to follow TB examinations.

Competing Interests: The authors declare that we have no competing interests.

Acknowledgements: The authors would like to thank Research Department of Universitas Airlangga for funding this research. The authors are grateful to thank all private practitioners who kindly consented to participate in this study. We sincerely thank to Health Office of Surabaya City for their support and provision of TB related epidemiological information.

Supplementation of Stenochlaena Palutris Micronutrient for Reducing Anemia During Pregnancy

Christine Aden[1], Asih Rusmani[1], Maria Julin Rarome[1]

[1]Ministry of Health Polytechnic,Palangka Raya, Indonesia

Abstract

Background: This research aims to raise an agricultural asset in traditional household diets in Dayaknese community in which it was believed that Kalakai (*Stenochlaena palutris*) might increase hemoglobin levels in pregnant women and breastfeeding mother. The objective of this research is to evaluate the effects of micronutrient supplementation during pregnancy.

Method: This research using a quasi-experimental was undertaken in Palangka Raya, Central Kalimantan in which the respondents received a menu-contained *Stenochlaena palutris* (as intervention). Independent t-test and paired t-test were used to examine group differences.

Result: The result between before and after intervention showed that Hb levels were 10.321 ± 0 .88 g/dl higher after intervention given compared to a point before invasion (9.628 ±1.01 g/dl) with a significant association test result (*ρ* value: 0.002).

Conclusion: According to correlation value, it suggested that about 34% of *Stenochlaena palutris* menu contributed to elevated Hb concentrations while the other random factors attributed the rest. Fe elements in a boiling *Stenochlaena palutris* may enhance Hb level.

Keywords: *Micronutrients, Stenochlaena palutris, pregnancy, Hb.*

Introduction

Anemia is one of the primary burden diseases in Indonesia in which its prevalence in pregnant women remains unchanged, according to the Indonesia Health Survey (RISKESDAS). It revealed approximately 24.5% of anemia prevalence each in 2007 and 2010[1]. However, the number was elevated considerably by 12.6% in 2013(1).

A tablet supplementation program which was established by the Ministry of Health, Republic of Indonesia was divided into two parts based on the number of tablets given during pregnancy (30 pills called Fe1 and 90 tablets called Fe. In 2003, Indonesia Government determined about 93% of pregnant women received 90 tablets of Fe.However, the number of tablet consumed was far less than expected. Only 17.5% of them did consume the tablet for more than 90 days as well as almost half of them consumed the pill less than 90 days. Although the rate of a proper Fe tablet consumption was low, the percentage of the opposite was a few. Palangka Raya is recorded as the lowest percentage of Fe tablet distribution (73.1% of a 30 tablet and 66.3% of a 90 tablet) compared to the other districtt(2).

However, the actual situation does not comply with government regulation.Until recently, people have not discovered an innovative health promotion for preventing anemia in pregnant women through pharmacology with *Stenochlaena palutris* as the main ingredient. Our data from a quasi nutrient supplementation trial in urban

Dayaknese were used to examine Hb levels throughout gestational age in relation to new menu contained *Stenochlaena palutris*.

The benefits of the research will be beneficial to a lot of people. The success of elevated Hb levels in pregnant women will contribute to them as it will be considered as an affordable method by utilizing local agricultural assets. Furthermore, it will complement government program for mitigating anemia by promoting *Stenochlaena palutris* being used in their daily menu.

Method

This research using a quasi-experimental was undertaken in Palangka Raya, Central Kalimantan in which the respondents received a menu-contained *Stenochlaena palutris* (as intervention). Independent t-test and paired t-test were used to examine group differences. The characteristics of the confounding factors which distinguish between pregnant women, age, education, parity, income, occupation, Fe tablet consumption were assessed. The quantitative research is owing to Fe measurement in *Stenochlaena palutris* and improving Hb levels in pregnant women. For the intervention group, pregnant women were assigned to receive a menu containing boiling *Stenochlaena palutris* while the control group was not designated for any treatment.

Results

Stenochlaena palutris content was assessed in a laboratory at Gajah Mada University. As shown in Table 1, it suggested that Fe levels in a 1-mnt boiling *Stenochlaena palutris* were 0,75 mg/kg. In contrast, there were approximately 0,36 mg/kg Fe in a 5 gr boiling *Stenochlaena palutris*. The highest levels of Fe in *Stenochlaena palutris* were found in unboiling leaves. (Table 1).

Table 1. Fe levels in a Package of Stenochlaena palutris Soup

Boiling Stenochlaena palutris				
r	Cooking Time	Result	Unit	Method
Fe	1 Minute	0.075	mg/100 gr	ICP
	5 Minute	0.036	mg/100 gr	ICP
Stenochlaena palutris Leaves				
Fe		0.384	mg/100gr	ICP

The initial planning of sample size with test power at 95% was required 23 eligible respondents in the trial group and another 23 in the control group. However, our respondents exceeded the minimum calculated sample (29 dan 42 respondents in trial and control groups, respectively).

The respondent characteristics represented inparity, education, occupation, gestational age, income. It suggested that about 69% of pregnant women were multipara with Hb levels at 10.3 g/dl after trial. More than half of them holding a higher education status had 10.3g/dl of Hb levels after trial (55.2%). Based on their occupation, Hb levels in their blood reached 10.4g/dl among 73.3% of them. It is also evident in 65.5% of them in their third trimester. In average, the age of respondents was 27.5 years old with 2.1 million rupiahs of income per month.

The result showed a significant value of ρ was >0.05. It indicated that the Hb level distributed normally. Therefore, the analysis proceeds to the independent t-test. The homogeneity test showed homogenous meaning that Hb levels in each group were more than 0.05.

The average of Hb levels was higher in the trial group than those in the control group(10.321 g/dl > 9.61 g/dl with Δ=0.711 g/dl). 95% CIwere 0.29 g/dl – 1.12 g/dl. Statistically, the average Hb levels in each group were different. It represented in ρ value <0.05. All above explanations, it is inferred that the study proved a statistically significant association between the intervention and improving Hb levels (10.3 g/dl ± 0.88 g/dl in the trial groupversus9.6 g/dl ± 0.84 g/dl in control group).

The average of Hb levels in the trial group was higher than in the control group (10.321 g/dl and 9.61 g/dl, respectively) with Δ 0.711 g/dl. 95% CIof the difference was 0.29 g/dl – 1.12 g/dl. Randomly, Hb levels between groups were considerably different. It can be seen in ρ value <0.05. The research conclusion revealed that the package-contained *Stenochlaena palutris* has Hb levels, which is higher than those in the control group. (10.3 g/dl ± 0.88 g/dl and 9.6 g/dl ± 0.84 g/dl, respectively).The average of Hb in Fe consumption was higher than it was in a group who did not drink Fe tablets in the trial group (10.35 mg/dl and 10.31 mg/dl, respectively) with a mean difference at 0.04 mg/dl.

It can be inferred that this study revealed an elevated Hb level at *0.04 mg/dl* in the group who have prescribed the *Stenochlaena palutris*Package and drank the

designated-Fe tablets simultaneously. From this group, their Hb levels exceeded the other group who did not consume. The result steamed from most likely due to limited time when the observation took about 10days to evaluate the intended effects.

Discussion

Education is a primary external factorfor pregnant women owing to a better understanding of given information, particularly in health education[3]. Inadequate level of mother's education (significant level < 0.05) may cause inappropriate daily intake during pregnancy. Therefore, this is the potential risk of suffering from anemia during pregnancy. The more well-educated the mothers, the better understanding of processing information. This may lead to a sufficient daily intake during pregnancy[38]. The attendances of mothers in the program reflect the self-awareness of mothers towards health prevention throughout pregnancy[4].

Multipara group made of approximately 63,4% of mothers. The result was in accordance with the previous studies[5]. They reported that mothers with parity less than 2 tended to have normal Hb levels, whereas mothers with multigravida showed abnormality. This indicates that equality plays leverage over HB levels (Table 1). In a healthy pregnancy, a hormonal change causes a high plasma volume, which leads to reducing Hb levels. This effect is deemed reasonable if the standards of Hb do not decrease at less than 11.0g/dl[6].

Most respondents were a housewife (83.1%) in which the status has a benefit in time flexibility, and In addition, the condition might be linked with income per month hence it will fill daily necessity during pregnancy. A variety of gestational ages affect daily intake of Fe in every trimester. In the first trimester, the adequacy of Fe is not as much as in the second semester while in the subsequent trimester, the Fe daily intake is higher in order to fill the suitability of fetal growth. Hb levels during the first and the second trimester are about 11.6 g/dl due to diluted blood (hemodilution-derived increased plasma volume)[45]. The above question is in conjunction with this research, reporting approximately 64.8% of mothers in the third trimester with anemia had Hb levels at 9,8 -10,1 gr/dl[7].

The package of *Stenochlaena palutris* soup is considered as an alternative attempt for improving mother's nutritional status during pregnancy in an area with many vegetables. Several studies revealed that *Stenochlaena palutris* leaves are the main ingredient in a side course which contains Fe at the highest concentrations of 50.169 ppm (5.017 mg/100 g) and the lowest levels at 4.087 ppm (0,408 mg/100g)[8].

The researchers utilized *Stenochlaena palutris* leaves, which were boiled at a specific temperature in 1-5 minutes. The *Stenochlaena palutris* were processed into meals that are served for pregnant women. After cooking, Fe levels were reduced with boiling time (table 1). Fe levels before a minute boiling were 0,38 mg/100gr while afterward were 0,075 mg/100 gr. Likewise, it was in a 5 minute boiling, and the Fe levels reached 0,036 mg/100gr. It is clear that Fe levels in raw *Stenochlaena palutris* leaves were 0,38mg/100 gr in which they nearly approached the lowest levels of Fe at 0,408 mg/100gr according to the previous standards[9].

Stenochlaena palutris leaves used in this research were bought from the local market in Palangka Raya. At the research time, *Stenochlaena palutris* leaves were not easy to be found because of the wet season and flooded peatland. The content of Fe was influenced by peatland structuresten, which has been thin due to forest fires.

Before trial, the Hb levels were 9.6 g/dl while afterward were 10.3 g/dl. This showed an increase after an experiment with a difference at 0.69 g/dl. In the control group, the average mean was 9.6 g/dl with a difference at 0.711 g/dl.

Fe non-hemeis penetrated easily in the body when it is consumedwith animal proteinsand vitamins C Vitamin C supplementation helps increased levels of Hb [10]. Vitamin C supplementation will improve Hb levels significantly if it is consumed with non-heme food sources[11]. Patin and Gabus fishes mixed with lemon squash were proven in optimum absorption of Hb levels in a trial group before and after trial. It rose to 0,69 g/dl. In total, Fe levels in *Stenochlaena palutris* soup were 1,8 mg/100 gr which were given consistently for ten days with 100-gram lemon squash. According to the preceded research, Eating vegetables and fruit-contained vitamin Csis essential in Fe absorptionup to 4 times higher.Fe supplementation and vitamin C are more effective to elevate Hb levels and the number of blood cells compared to the sole supplementation either Fe or Vitamin C.

In 100 gram oranges contains Vitamin Cs at 49 mg. It is also found in Jambu monyet, Jablang, Jambu Putih, gandaria, mangoes which comprise of vitamin C more

than oranges fruit in which in a 100 gr jambu monyet contains197 gram, 130 mg, 116 mg, 111 mg, 61 mg vitamin C, respectively. Oranges were chosen in this research because of its affordable prices as well as its ubiquitous fruit.

A pregnant woman needs 85 mg/day of vitamin C[12]. *Stenochlaena palutris* leaves contain 219,7 mg per 100 g of Vitamin Cs. Vitamin C is stable in the dry state and will damage easily in the dissolved statedue to oxidation, which is catalyzed by the presence of Cu and Fe. In this research, vitamin C in *Stenochlaena palutris* leaves did not exist in *Stenochlaena palutris* leaves because of boiling[13]. Vitamin C intake in a pregnant woman for ten days was foreseen as adequate because it derived from lemon squash at 50cc of 1 orange contained vitamin Cs (100 gr) at 49 mg. In the field, vitamin C was administered at more than 100-150 cc, considering respondents' requests.

It is evident that 30.4% of *Stenochlaena palutris*-basedimproved Hb levels in pregnant women, and the rest was due to random factors which were not covered in this research. About 75% anemia in pregnant women are due to Fe and folate acid deficiencies as well as vitamin B12 deficiency (anemia megaloblastic) The other precursor agents of it are hemoglobinopathy, inflammation, chemical toxicity, and malignancy[14].

Due to itsprices and ubiquitous vegetables, *Stenochlaena palutris* leaves were urged by researchers to be additional meals for nutritional adequacy. In line with government program of 90 Fe tablets, therefore, PKM encourages its attendances to consume *Stenochlaena palutris* leaves. This implementation was run as part of the government program. Likewise, the package was a source of Fe non-heme in which it may catalyze the absorption aiming to maximize Fe levels until their parturition.

Conclusion

Result of this research the effects of micronutrient as Fe contained *Stenochlaena palutris*,that 30.4% of *Stenochlaena palutris* based reduces anemiafor pregnant women.Promotive and preventive attempts may be in the form of promotion of Fe supplementation regularly every month as well as providing health education owing to the utilizing of local agriculture, for instances, *Stenochlaena palutris* leaves, and lemon squash or orange squash. For pregnant women, it is expected that encouraging to raise their awareness and promoting the importance of health prevention during pregnancy and parturition. There are many ways to achieve that are routinely visiting hospitals owing to prenatal care and consume Fe tablets while combined with additional vegetables for instances, oranges, or lemon squash in order to increase Hb levels.

Ethical Clearance: Ethical clearance was obtained from the Semarang Ministry of Health Polytechnic. We also wish to thank all the participants who contributed to this study.

Conflict of Interest: Nil.

Source of Funding: Nil.

Factors Causing Bangkalan Communities to Consume Earthworm Boiled Water (Drugs/Traditional Remedies) for Typhoid Handling

Dining Fijri Radina[1], Irwanto[2], Annis Catur Adi[3]

[1]Student Master of Public Health at Airlangga University Surabaya, Indonesia, 60115, [2]Department of Child Health, Faculty of Medicine, Airlangga University Surabaya, Indonesia, [3]Departement of Nutrition, Faculty of Public Health, Airlangga University Surabaya, Indonesia, 60115

Abstract

Based on Riskesdas data in 2013, Bangkalan District one of the districts with high typhoid case is Bangkalan Regency. The high number of typhoid cases and various other cases were not proportional compared to the visit of medical facilities in Bangkalan. On the other side, the use of traditional medicine in Bangkalan is high based on BPS in 2014. In the Madura ethnic (/tribe) especially in Bangkalan Regency there is a local wisdom about using earthworm decoction as a solution for handling typhoid fever particularly for children . This research aims to identify the causes of the people in Bangkalan in consuming earthworm decoction for typhiof treatment. This study used a qualitative method in the form of interviews of 3 producers and 6 consumers. This study was conducted in 3 production locations of earth decoding in Bangkalan sub-district, Bangkalan regency. This study was held in January 2019. The sampling technique that was used in this study was purposive sampling. Based on the study that has been done about the cause factor of people in Bangkalan consuming earthworm decoction for typhoid treatment, it was Showed that there are various factors behind it such as personal choice (comfortable using traditional medicine), marketing (well -known), culture (habitual), psychological (cure faster) and accessibility (easily available). Beside those factors, there are other factors namely natural ingredients and no side effects.

Keyword: *traditional medicine, typhoid, earthworm*

Introduction

Typhoid fever is a health problem that still needs attention. Case prevalence varies depending on location, local environmental conditions and community behavior. WHO estimates that the number of typhoid fever cases around the world is around 17 million people per year with a mortality rate reaching 600,000 people each year, which is about 3.5% of all cases. 70% of typoid fever cases occur in developing countries in Asia. The number of deaths in Asia annually reaches 420,000 cases. Typhoid fever is still a global health problem, due to the high incidence

Indonesia is one of the countries with a high incidence of typhoid fever, Indonesia's Health Profile in 2015 recorded typhoid fever, including the top 10 diseases in hospitals. The number of typhoid fever sufferers in Indonesia alone is reported at 81.7 per 100,000 population with distribution according to age group 0.1/100,000 population (0-1 years), 148.7/100,000 population (2-4 years), 180.3/100,000 population (5-15 years) and 51.2/100,000 population (≥16 years). This figure shows that most sufferers in the age group 2-15 years. The number of typhoid events in Indonesia in 2015 was 298,687 people.(1)

The latest data related to typhoid notes that based

Corresponding Author:

e-mail: dining.fijri.radina-2017@fkm.unair.ac.id

on the Early Awareness System and Response of the Ministry of Health in 2016, typhoid is still the top 10 diseases that occur in the community, so it still needs serious attention.

Based on 2013 Risesdas data, Bangkalan is one of the districts in East Java with typhoid cases above the provincial average and is among the top 10 districts with the highest typhoid cases. The high number of typhoid cases and various other cases is not comparable with Bangkalan community visits to health facilities, this is needed by the patient coverage in Bangkalan which is still low compared to the target including: coverage of outpatient visits 47.02% while the target is 89.2% and coverage Outpatient visits were 11.5% while the target was 26.59%. [(2)] On the other hand the use of traditional medicines in Bangkalan District is quite high, based on BPS data in 2014 54.63% of the population in Bangkalan District did not seek treatment when sick while 45.37% treated. of 45.37% of those treated, 28.86% used traditional medicines and other non-medical drugs.

In the Madura tribe, especially in Bangkalan Regency, there is local wisdom by using boiled water as an solution for handling typhoid fever, especially in children. The use of traditional medicine is not only applied to Indonesian society but is also used in many world populations. Based on WHO reports 80% of Asian and African populations use traditional medicine (TM) to meet health care needs. [(3)]

Traditional medicine has so far been considered contrary to medical treatment, whereas the integration between traditional medicine and modern medicine has been recommended by WHO since 1978 with the ultimate goal of improving health status. WHO's focus on traditional medicine is contained in the WHO 2014–2023 Traditional Treatment Strategy which has two main objectives, one of which is to support Member States in exploiting the potential contribution of traditional and complementary medicine to health . [(4)]

Treatment using traditional medicine with natural ingredients contributes to modern medicine. [(5)] Natural ingredients that form the basis of traditional medicine show some differences in their effects, chemical structure and biological activity in their use. [(6)]

The problem in this study emphasizes more on the factors that cause people in Bangkalan to consume traditional medicines/ingredients, namely boiled water for earthworms for handling typhoid. Thus this study aims to mengeta h ui causative factor in Bangkalan community earthworms consume boiled water (medicine/traditional ingredients) for the treatment of Typhoid

Method

This research is a qualitative study conducted in Bangkalan Regency in January to June 2019. The sampling technique used was *purposive sampling* . The sample in this study was divided into two: 3 producers selected from 3 places for making earthworm cooking water in Bangkalan Regency among others in Pangeranan and BancaranVillages, Bangkalan District and in Keleyan Village, Socah District and 6 consumers found during the visit in a place for boiling water for earthworms with various different backgrounds

Results

The custom of using traditional medicines in the Madura community especially in Bangkalan Regency has been going on for a long time. Recorded in the book "Dissecting the Secrets of Madura Potion" that consuming herbs/traditional medicine is a hereditary tradition and has even been familiarized since childhood.

Specifically for habits of consuming boiled water earthworms are only taken when a fever (which does not recover with medical treatment). Based on an interview with one of the consumers, she ordered boiled water for earthworms for her child who still has a fever despite being taken to the doctor. According to him more effective again after seeing the doctor then proceed with drinking boiled water for earthworms h. Previous studies have also explained that some patients have the perception that the use of traditional medicines together with pharmaceutical drugs can affect treatment outcomes for the better. [(6)]

Apart from being a companion to medical drugs, there are parents who give boiledwater for earthworms as soon as their child has a fever without being treated to the doctor because there is a previous experience when their child has a fever to recover with boiled water for earthworms.

The process of making boiled water for earthworms in 3 research locations tends to be the same, based on interviews with earthworm makers in Bangkalan, the manufacturing process is about 20 earthworms cleaned from the ground and dirt that clings to water many times,

until it feels clean then boiled with 3 cups water until cooked.

A different thing is found in the location of earthworm cooking water in Bancaran Village, which is an earthworm cooking water innovation. Not only earthworm stew like in general but there are made the worm that is boiled earthworm water mixed with a jar (a type of fruit or seed from a tuba teak tree). Earthworm boiled water mixed with tempayang makes the cooking water brownish with a sweet aroma like tea, so it is called worm tea. The origin of this innovation according to the makers of worm cooking water, is because many children and even adults do not want to drink earthworm cooking water because it tastes bad, so it is hoped that the shape resembles that of small children who want to drink earthworm cooking water. Earthworm cooking water is sold at the same relative price in 3 locations, 15-20 thousand for 1 medium size bottle with the rule to drink 1 bottle for 1 day.

Then based on interviews with earthworm makers in Bancaran, Pangeranan and keleyan, on average, 10 to 30 bottles of boiled earthworm boiled water are sold in one day and the buyers come from Bangkalan District, Burneh District, Socah District, Tanjungbumi District and other districts. Some even bring earthworm boiled water to outside the Bangkalan region such as to Sampang, Sumenep, Surabaya and other areas. Besides being sold in the form of boiled water, some are also sold in the form of worms in clean condition (already washed, just boiled). Sales of clean earthworms can be ordered at the worm water producers located in the Socah Subdistrict of Keleyan, while in Bangkalan Subdistrict precisely in Pangeranan and Bancaran Villages only accept orders in the form of medium-sized (600 ml) earthworms and large-size (1.5 ml) boiled water L).

Based on the results of interviews with the makers of boiled water for earthworms when asked about the efficacy of boiled water for earthworms

"Aeng worms can be used for typing polanna almost all who drink the heat down (earthworm water can be for typhoid because almost all consumers who drink boiled water of earthworms tell that their body temperature gradually decreases)" (IU 5)

"Earthworm water is the intermediary for your recovery, because the earthworm's cooking water cools the body" (IU 6)

"Treatment is suitable - suitable, incidentally many earthworm water is suitable for reducing heat" (IU 7)

Based on interviews with consumers or ordering boiled water for earthworms the reason for consuming it is because there are no side effects, prefers natural remedies, feels that consuming boiled earthworms can cure typhoid fever, experience of previous success,

"There are no side effects due to natural circumstances although I work at the pharmacy but prefer natural ones" (IU 6)

"Get better soon than medicine after drinking the heat down here is well known for typing ya order worm water here" (IU 7)

"It is suitable here, it has been a subscription from the first if it's already hot like I want to type directly order here" (IU 8)

"It's easy to get a message through the telephone then made finished can be taken ordirectly come here, here immediately ready morning message afternoon or evening just take" (IU 9)

"It's a lot if it's hot to go to the doctor, it's easy to drink worm water again" (IU 8)

"It has been treated, it does not go down and down, so the order of worm water usually goes down" (IU 9)

Discussion

Based on studies that have been carried out regarding the factors that cause people in Bangkalan to consume boiled water for earthworms (medicine/ traditional ingredients) for the treatment of typhoid shows that there are various underlying factors including personal factors (Suitable to consume traditional herbs), Marketing Factors (Famous), Factors Culture (Habit), Psychological Factors (Heal faster) and Access Factors (easy to obtain) besides that there are other Factors namely natural ingredients and no side effects This is in accordance with research by Pramono which states that traditional medicine is mixed from the ingredients provided nature, so it's safer. [7] Does not contain chemicals, without side effects and can be obtained cheaply so that cost savings are similar to the research conducted by Ganik, the reason for consuming traditional ingredients compared to medicine is because they come from natural ingredients so it is safer, has no side effects and the price is also cheaper. [8]

The results of interviews with respondents are also in line with research conducted in Bangkalan in 2016 by Andriati regarding the reason Bangkalan people consume drugs/traditional ingredients include: Personal factors namely feeling fit to consume traditional medicines/ herbal ingredients, marketing factors are advertisements obtained from people closest to either family, or community members, social factors, namely the advice of those around him (family, friends, colleagues, etc.).(10)

Cultural factors due to traditional medicines/herbal concoctions have been cultivated early on, Psychological factors due to deadlock (not cured) when taking pharmaceutical drugs (modern drugs) so that switching or consuming traditional medicines that are considered more able to cure the disease, the price factor due to traditional medicines/herbal ingredients are relatively affordable.

While other research shows, the factors that encourage people who choose traditional medicine are caused by various things, which are divided into internal and external factors of the patient. Internal factors, including lack of knowledge about health, beliefs and perceptions that traditional medicine can cure diseases. External factors, namely supporting factors include the distance that is close enough and the cost is cheap. Other external factors are driving factors which are rigid social impulses, culture which always dictates classical traditions and disease severity . (11)

Based on interviews there were respondents who directly compared traditional medicine with medical treatment and chose traditional treatment because it was more natural, no effect, cheaper and effective, easier to access than health workers. Some reasons for the respondents are in line with the reasons for consuming traditional ingredients compared to drugs according to Ganik because they come from natural ingredients so it is safer, has no side effects and the price is also cheaper. And easier access than to health facilities. [8] It is also in line with Pramono that mixed traditional medicine of materials - materials that nature provides, so it's safer. Does not contain chemicals, without side effects and can be obtained cheaply so that it is cost effective.(7)

However, previous studies have shown that boiled water for certain concentrations of earthworms does not inhibit the growth of *Salmonella typhosa* bacteria.(9) Therefore, further research is needed regarding the benefits of consuming earthworm traditional medicines for the treatment of typhoid fever.

Conclusion

Many things cause people to use traditional medicines although traditional medicine has not been clinically proven compared to medical treatment. The community believes that boiled water is more natural, without side effects, is well-known among the community, is easily accepted by the community, is a local custom and is easily available.

Suggestion: Various approaches are needed so that people move from traditional service to health services.

The Influence of Emotional Support and Tradition on the Mother's Decision to Select Birth Attendants in Kaiwatu Village, Indonesia

Elsa Ruth Rode Maromon[1], Ernawati[2], Rachmat Hargono[3]

[1]Master of Public Health Program, Faculty of Public Health, Airlangga University, Surabaya, Indonesia, 60115, [2]Department of Fetomaternal, Faculty of Medicine, Airlangga University Surabaya, Indonesia, 60131, [3]Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Airlangga University Surabaya, Indonesia, 60115

Abstract

Maternal Mortality Rate (MMR) is the number of maternal deaths during pregnancy, childbirth and childbirth caused by pregnancy, childbirth and childbirth or its management but not due to other causes such as accidents or falls in every 100,000 live births . This indicator is to assess the maternal health program and the degree of public health, because of its sensitivity to improving health services, both in terms of accessibility and quality. Delivery assisted by health workers is proven to contribute to the decrease in maternal mortality ratio . Competent health workers who provide birth assistance can have the opportunity to provide education related to Early Breastfeeding Initiation, exclusive breastfeeding and even care during the postpartum period. This study aims to analyze the influence of the support of social and cultural to decision helper mothers choose birth not health workers . This research is a descriptive study with qualitative method. Data collection is done by in-depth interviews, participatory observations and secondary data. Research informants are mothers who have given birth in the last 5 years in Kaiwatu village. The results showed the mother's decision to choose a birth attendant birth attendant was influenced by emotional support and tradition. Therefore, mothers in Kaiwatu village tend to choose birth attendants.

Keywords: *Emotional support, tradition, birth attendants.*

Introduction

Maternal Mortality Rate (MMR) is the number of maternal deaths during pregnancy, childbirth and childbirth caused by pregnancy, childbirth and childbirth or its management but not due to other causes such as accidents or falls in every 100,000 live births . This indicator is to assess the maternal health program and the degree of public health, because of its sensitivity to improving health services, both in terms of accessibility and quality. (Kementerian Kesehatan, 2016).(1)

According to data from the Central Statistics Agency (CPM, 2016), the maternal mortality rate in Indonesia by island, Nusa Tenggara, Maluku and Papua has the highest MMR, which is 489 per 100,000 live births, then followed by the island of Kalimantan by 466 per 100,000 live births and The lowest MMR on Java and Bali was 247 per 100,000 live births.(2)

Delivery assisted by health workers certainly greatly contributes to improving maternal and child health. Competent health workers who provide birth assistance can have the opportunity to provide education related to Early Breastfeeding Initiation, exclusive breastfeeding and even care during the postpartum period.

Based on data from the Kementerian Kesehatan Indonesia (2018), coverage of birth attendants by health workers in health facilities in Indonesia has fluctuated in the last three years. In 2015 it was 88.55%, but it dropped to 80.01% in 2016, increasing again in 2017 by 83.14%. Furthermore, coverage of childbirth assistants by health workers in a facility in Maluku province has also fluctuated in the last three years. In 2015 as many as 46, 90%, down to 25.71% in 2016, then in 2017 increased to 30.65%.[3]

Data from the Maluku provincial health office, in 2016 coverage of deliveries assisted by health workers in the health facilities in Southwest Maluku regency ranked second as low as 7.9%, then in 2017 it increased to 19.74% and 2018 as much as 22.36%. Although it has increased every year, but this is certainly not yet reached the target set in the Strategic Plan of the Department of Health in 2015, namely births attended by a health worker by 80% (Dinas Kesehatan Provinsi Maluku, 2019).[4]

Based on preliminary studies conducted by researchers, pregnant women in Kaiwatu village tend to choose birth attendants by birth attendants. Out of 10 pregnant women, 7 people preferred birth attendant birth attendants, 3 others chose health workers because they experienced difficulties at delivery. This is consistent with data obtained from the Tiakur Health Center in the last three years showing that, coverage of birth attendants assisted by TBAs in Kaiwatu village tends to increase . In 2016 as much as 87%, increased in 2017 as much as 93% and in 2018 it increased again to 95%, while the coverage of birth attendants by health workers was highest in Tiakur village and continues to increase. In 2016 as much as 92%, in 2017 as much as 93%, increasing again in 2018 as much as 95%.[5]

The impact of the low birth attendance by health workers in the village of Kaiwatu, is that the coverage of IMD and exclusive breastfeeding is very low because maternity mothers who are assisted by birth attendants do not do IMD so that it will certainly affect the coverage of exclusive breastfeeding as well. Lack of knowledge and certain beliefs sometimes affect the mothers so as not to give colostrum to babies like in the village of Kaiwatu, colostrum is milked by hand and discarded. This means that Kaiwatu village is one of the villages that affects the low coverage of IMD and exclusive breastfeeding in Southwest Maluku district. Data on the health profile of the Maluku province in 2015 showed that IMD coverage in the Southwest Maluku district was 5%, while exclusive breastfeeding coverage was 9.3%.[6]

In addition, the ratio between the number of residents and health workers in Kaiwatu village, which is 700 residents: 3 doctors, 4 midwives, 8 nurses, then access to health facilities is relatively easy and the distance traveled is also very close, but the local communities who are indigenous and settled there prefer helper non-health delivery, if not experiencing difficulties at delivery. Based on the background and identification of the problems above, the researcher wanted to examine the "Influence of Emotional Support, Social Networking Support and Tradition Against the Decision of Mothers Choosing Birth attendants Delivery Assistance in Kaiwatu Village, Indonesia ".

Method

This research is a descriptive study with qualitative method. Data collection is done by in-depth interviews, participatory observations and secondary data . In setting informants, researchers used snowball sampling techniques. With this snowball sampling technique, the researcher chose one mother who is a native of Kaiwatu village who gave birth in the last five years with the help of delivery of health and non-health workers who will be key informants to further provide clues as to who other key informants can provide further information . In this study, researchers used two types of triangulation, namely source triangulation and technique triangulation.

Triangulation source, to test the credibility of the data is done by way of checking the data that has been obtained through several sources. Triangulation of this source is used by researchers to check data from traditional healers, health workers, hus Bands and families. While triangulation techniques to test the credibility of the data is done by way of verifying data to the same source with different techniques. Triangulation of this technique is used by researchers after getting interview results which are then checked with the results of observation and documentation. of the three techniques, of course, will produce a conclusion related to the influence of emotional support, social networking support and tradition on the decision of mothers choosing birth attendants instead of health workers .

Results

Kaiwatu Village is one of the villages in Maluku Province, Southwest Maluku Regency, Moa District.

The total area of the village of Kaiwatu amounted to 5,417.228 ha with a population of 700 inhabitants (CPM, 2018).[7] Informants in this study were 6 key informants and 10 triangulation informants .

The results showed that emotional support influenced the decision of mothers to choose birth attendants by non-health workers or traditional birth attendants.

"*Yes, when my stomach started hurting, my hus Band and mother did go to call a birth attendants to help my childbirth ...*" (WS.31 years)

"The *family is very supportive because it happens that my grandmother isa birth attendants so the family would support later discussion is convenient because when it starts to contract again the birth attendants massage my waist ...* "(SS.30 years).

"*The family recommends to the TBA because it has been proventheir service is very good, friendly to the community whenever we give birth they are ...*" (IN.25 Years)

"*All the family was there when I gave birth at home so I wasn't worried, if in hospital only can be accompanied by one person, hus Band or other family..*"(YP.25 Year).

"*Families take care during the puerperium, starting from the need for food to take a shower and even wash my child's clothes ...*" (PP. 29 Years)

The hereditary tradition in the family also influences the decision of mothers in choosing birth attendants by non-health workers.

"A *long time ago, if our family gave birth then it is only helped by birth attendants, so it has been proven that the service is good. During helped not died, some acquaintances giving birth in hospital actually died whereas helped by midwives and doctors ...*" (WS.31 Years).

"The Birth attendants took care of me until my child's umbilical cord fell, bathing me and my child, besides massaging me after 1 week of giving birth ..." (OT. 20 years).

"*Birth attendants always massage in the third trimester and after giving birth. I prefer birth attendants because the service is better...*" (SS. 30 Years).

"*The birth attendants massages after one week of giving birth, giving herbal concoctions to drink, the baby is warmed using a baked handkerchief in embers, making hundred to tighten the vagina ...*" (YP. 25 years).

Discussion

Social support factors can influence the decision of mothers to choose birth attendants, both health and non-health workers. The social support factor in this study is emotional support. Sarafino (2011), suggests that emotional support include expressions of empathy for example, listen, be open, showing the attitude of believers towards what is complained of, to understand, expressions of affection and concern for someone who will make an impact positive to reduce the anxiety that makes feel valuable, comfortable, safe, secure and loved.[8]

The study results in Kaiwatu village show that the decision of mothers to choose a birth attendants birth attendant is strongly influenced by emotional support from the family. Hus Band and family play an important role in the process of giving birth. Hus Band and family play an important role in the process of giving birth. Hus Band and family play a role in determining birth attendant birth attendants because based on previous experience, birth attendants provide the best services so that mothers and families are more comfortable if the birth attendants help during labor and it has been proven that no mothers and babies have died. This study is also consistent with research conducted by Hidra (2017) in the working area of the Pasir Putih Puskesmas, Muna Regency, showing that family support greatly influenced the decision of mothers to choose birth attendants for health workers by 56.8% and non-health workers by 43.2%.[9]

Culture is one aspect that can not be separated in human life. The results of this study indicate that cultural actors who can influence a mother's decision to choose not health workers or birth attendants, namely the trust of local communities and hereditary traditions. Birth attendants have the advantage of services that cannot be performed by health workers, namely massaging the mother before giving birth to correct the position of the fetus so that during birth the right position Besides that another advantage is that after giving birth the birth attendants also massages as well as provides herbal concoctions for the mother and roughens the mother's vagina so that the wounds caused by childbirth are quickly healed.

The results of this study are consistent with studies

conducted by Aryani and Islaeni (2018) in the Riau Islands, showing that mothers prefer birth attendants by birth attendants because they have advantages in the eyes of the community, namely because birth attendants provide massage or ingredients during labor that are not obtained by the community if doing per copy at a health facility.[10]

In addition, research conducted by Lestari and Agustina (2018), shows that people believe in birth attendants more because birth attendants have an important role in socio-religious positions in society.[11] Aside from being a helper for childbirth, the advice and suggestions from the birth attendants have influence in determining the facilities. Studies conducted by Preis et al (2018) at the Women's Community Health Center in Metropolitan Israel, show that mothers have confidence that labor is natural so there is no need for medical intervention.[12]

Conclusion

Mothers' decisions choose birth attendants instead of healthcare workers affected by the emotional support and tradition. Therefore, mothers in Kaiwatu village tend to choose birth attendants instead of health workers.

Suggestion: Emotional support and information from health workers need to be seen again its influence on mothers in choosing delivery helpers. In addition, social networking support also needs to be investigated to see how much influence it has on mothers in determining birth attendants.

Acknowledgments: On this occasion the authors would like to thank all the informants who have been willing to participate to provide true expertise for this research.

Conflict of Interest: There is no conflict of interest.

Abstract

Background: Liquorice is one of the most commonly used medicinal herb in Egypt as it has many pharmacological activities including anti-inflammatory and anti-allergic effects that encourage its use in asthma. Aim: evaluate the efficacy and safety of aqueous liquorice extract in asthmatic patients.

Method: our study included 127 asthmatic patients who were classified into 3 groups which are, group 1(placebo group) maintained at inhaled corticosteroids (ICs) and long-acting beta agonist (LABA) and received starch capsules (500 mg starch) three times daily as placebo, group 2 maintained at ICs and LABA and received liquorice capsules twice daily and group 3 maintained at ICs and LABA and received liquorice capsules three times daily and the study lasts 4 weeks. Blood and sputum eosinophils %, pulmonary function test asthma control test (ACT) score, serum potassium level and blood pressure were measured before and after the 4 weeks of the study.

Results: Only 95 patients completed the study and the results showed that liquorice in group 2 and 3 resulted in no significant reduction in blood and sputum eosinophils %. However, it significantly improved Forced Vital Capacity %, Forced Expiratory Volume % in one second and ACT score. Neither blood pressure (systolic and diastolic), nor serum potassium level showed any change in group 2. However, there was a significant elevation in systolic and diastolic blood pressure and reduction in serum potassium level in group 3.

Conclusions: liquorice significantly improved the pulmonary function in both the lower and higher doses used in the study, however the lower dose of the extract was safe and increasing this dose resulted in a significant elevation in systolic and diastolic blood pressure and reduction in serum potassium level.

Keywords: *Asthma, liquorice, pulmonary function, potassium, blood pressure.*

Introduction

Asthma is a heterogeneous disease characterized by chronic airway inflammation with variable expiratory airflow limitation[(1,2)]. There are many inflammatory cells involved in asthma pathogenesis as eosinophils that play important roles in the asthma development. Blood and sputum eosinophils are usually increased in patients with uncontrolled asthma and thus can be taken as indicators to the degree of asthma control[(3)]. Pulmonary function parameters like Forced Vital Capacity (FVC) and Forced Expiratory Volume in one second (FEV_1), can also be helpful in the determination of the severity of the disease.

Liquorice has been used in traditional Chinese medicine (TCM) in productive cough and liver

diseases [4]. The main active ingredient of liquorice is glycyrrhizin is responsible for the anti-inflammatory activity of liquorice as it inhibits 11β- hydroxysteroid dehydrogenase (11-β-HSDH), the enzyme responsible for the metabolism of cortisol to cortisone, resulting in cortisol accumulation[5]. Serious side effects of liquorice were reported that include hypertension and hypokalemia and these effects are mainly due to glycyrrhizin that makes a state of apparent hyper mineralocorticoid due to cortisol accumulation that activates the renal mineralocorticoid receptors [6]. Many studies were made to estimate the safe dose of liquorice as a study made on 24 healthy subjects who took aqueous liquorice extract pills and the results of this study revealed that a dose of liquorice extract equivalent to 217 mg daily of glycyrrhizin produced no side effects [7]. Another study, made on 20 healthy volunteers showed that high dose of liquorice (equivalent to 370 mg glycyrrhizin once daily) increased both systolic and diastolic blood pressure (S BP and DBP) significantly[8].

Patients and Method

Study Design: This study is a parallel randomized controlled trial in which 127 patients of chronic stable, moderate bronchial asthma were enrolled. Patient selection was done randomly from the outpatient clinic of the Cardiothoracic University Hospital, Minia University. Patients were classified into 3 groups. Group 1 included 43 patients and they were maintained at their usual asthma treatment ICS (fluticasone in moderate to high doses) plus LABA (salmeterol) and received a 500mg maize starch capsule 3 times daily as placebo. Group 2 included 44 patients and they were maintained at the same asthma treatment as group 1 in addition to 500mg aqueous liquorice extract capsule (equivalent to 100mg glycyrrhizin) twice daily [the extract was purchased from the Changsha Zhongren Biotechnology Company, Hunan, China (Mainland). Group 3 included 40 patients and they were maintained at the same asthma treatment as group 1 in addition to liquorice capsule three times daily. The study lasted for 4 weeks. The followings were excluded from the study: hypertensive patients, patients in acute asthma exacerbation, patients with heart diseases, especially those taking digoxin, pregnant and lactating mothers and women taking oral contraceptives.

All patients were subjected to:

Full medical history and routine clinical examination: It includes name, age, sex, smoking ,symptoms of asthma as cough, wheeze and dyspnea and history of hypertension. Routine general and chest examination was also done. Blood pressure (BP) was measured.

Blood eosinophilic % determination: One milliliter of venous blood was collected for complete blood count (CBC). Blood smears were stained with Leishman stain to confirm eosinophil count. Normal values of eosinophils% in the blood is up to 4%[9].

Sputum eosinophilic % determination: Equal volumes of phosphate buffer saline and acetyl cysteine 20% were added to the sputum sample and the samples were examined microscopically. Total leukocyte count was done manually using a hemocytometer Normal values of eosinophils % in the sputum is up to 2% [10]. This test was done at the baseline and after 4 weeks of taking the medication.

Serum K level determination: Ion selective electrode ST-200 Sensacore Medical instrumentation PVT LTD, India was used. Normal serum potassium level is (3.5-5) mEq/l [11]. This test was done at the baseline and after 4 weeks

Pulmonary function test: Spirometry was performed using Spirostik that is a USB- spirometer.

Asthma Control Test (ACT): This test is composed of 5 questions, each answer has a score and then the total score was calculated. Scores from 20-25 indicate a well-controlled asthma, Scores from 16-20 indicate not well-controlled asthma and Scores from 5-15 indicate a very poorly-controlled asthma.[12]

Statistical method: Data were collected from the patients and revised, verified, coded and then entered PC for statistical analysis done using IBM SPSS statistical package version 20[13]. Kolmogorov-Smirnov for normality test was used to differentiate between parametric data and non-parametric data. Numeric data were displayed as the median and interquartile range (IQR). Categorical data were displayed as number and percent and the comparison between the three studied groups was done using Kruskal Wallis and chi-squared test while the paired comparison was done using Wilcoxon signed-rank test. The P - value is considered significant at <0.05.

Results

Only 95 patients have completed the study. Regarding the demographic data (age, sex, and smoking), it was found that there was no statistically significant differences in the median age , sex and smoking of patients in the three groups as shown in table 1.

Table 1: Demographic data of patients enrolled in the study.

Data		Group 1 n=40	Group 2 n=40	Group 3 n=15	P-value
Age in years	Median (IQR)	26.5 (25-34) 14-47	30 (23.25-40) 16-36	30 (25-34) 16-40	0.176
Sex: n (%)	Males	24 (60%)	15 (37.5%)	7 (46.7%)	0.130
	Females	16 (40%)	25 (62.5%)	8 (53.3%)	
Smoking: n (%)	Yes	20 (50%)	12 (30%)	5 (33.3%)	0.165
	No	20 (50%)	28 (70%)	10 (66.7%)	

Group 1: This is the control group and patients were maintained on inhaled corticosteroids (ICs) and long acting beta agonist (LABA) and received starch capsule twice daily as placebo , Group 2: patients were maintained on (ICs) and (LABA) and received liquorice capsules twice daily, Group 3: patients were maintained on (ICs) and (LABA) and received liquorice capsule three times daily. IQR is the interquartile range

NB: Each capsule contains 500mg aqueous liquorice extract capsule (equivalent to 100mg glycyrrhizin).

It was found that there were no statistically significant differences in the measured parameters between the three groups before the start of the study as shown in table 2.

Table 2: Baseline blood and sputum eosinophil%, blood pressure, pulmonary function and ACT score in patients enrolled in the study (Data are presented as Median and interquartile range IQR).

Data	Group 1 n=40	Group 2 n=40	Group 3 n=15	p-value
Blood Eosinophils %	2.5 (2-4)	2 (2-3)	2 (2-3)	0.622
Sputum Eosinophils %	2 (1-4)	2 (1-2)	2 (1-2)	0.158
Serum K(mEq/l)	4 (3.8-4)	3.9 (3.8-4.3)	3.9 (3.8-4.3)	0.979
SBP(mmHg)	115(100-120)	125 (100-125)	120 (100-120)	0.475
DBP(mmHg)	85 (70-85)	75(70-80)	80 (70-80)	0.112
FVC %	80 (64-86)	90 (68-95)	78 (64-81)	0.160
FEV1%	84 (74-91)	89 (78-90)	87 (75-91)	0.134
ACT score	15 (14-16)	14 (12-17)	14 (11-15)	0.629

SBP is the systolic blood pressure, DBP is the diastolic blood pressure, FVC is the forced vital capacity, FEV is the forced expiratory volume and ACT is the asthma control test.

Regarding liquorice efficacy, the results of the reduction in blood and sputum eosinophils % show that there was no significant reduction in both blood and sputum eosinophils % in group 2 and 3 when compared to group 1. In addition, there was no significant reduction in blood or sputum eosinophils in group 3 when compared to the reduction in blood and sputum eosinophils in group 2. There was a highly significant increase in FVC % in group 2 and 3 when compared to group 1, while there was no significant increase in FVC % in group 3 when compared to group 2. Similarly,

there was a significant increase in the FEV1 % in group 2 and 3 when compared to group 1, however, there was no significant increase in the FEV1 % in group 3 when compared to group 2. On the other hand, it was found that ACT score was a statistically significantly increased in group 2 and 3 when compared to group 1, while there was no statistically significant increase in ACT score in group 3 when compared to group 2 as shown in table 3.

Table 3: Changes in blood and sputum eosinophilic %, pulmonary function and ACT score in patient groups. (Data are presented as Median and interquartile range IQR).

Data	Group 1 n= 40	Group 2 n= 40	Group 3 n= 15	P1	P2	P3
Blood eosinophil % Reduction	0.5(0-2)	0(0-1.75)	1(0-2)	0.857	0.665	0.545
Sputum eosinophil % Reduction	0(0-1)	0(0-1)	0(0-1)	0.528	0.746	0.746
FVC % Increase	0.5(0-5)	8(0-18)	6(4-11)	0.003	0.005	0.560
FEV1 % Increase	2(0-4)	6(0-13)	7(1-15)	0.027	0.005	0.054
ACT score Increase	5(2-7)	7(3-9)	8(5-8)	0.032	0.023	0.180

P1: group 2 vs. group 1, P2: group 3 vs. group 1 and P3: group 3vs. group 2. FVC is the forced vital capacity, FEV is the forced expiratory volume and ACT is the asthma control test.

It was found that serum K level was not significantly changed in group 1 and 2 ,while in group 3, the serum K level was very highly significantly decreased as shown in figure 1.

Besides, both SBP and DBP were not significantly changed in group 1 and 2 ,while in group 3 both SBP and DBP were significantly increased in group 3 as shown in table 4.

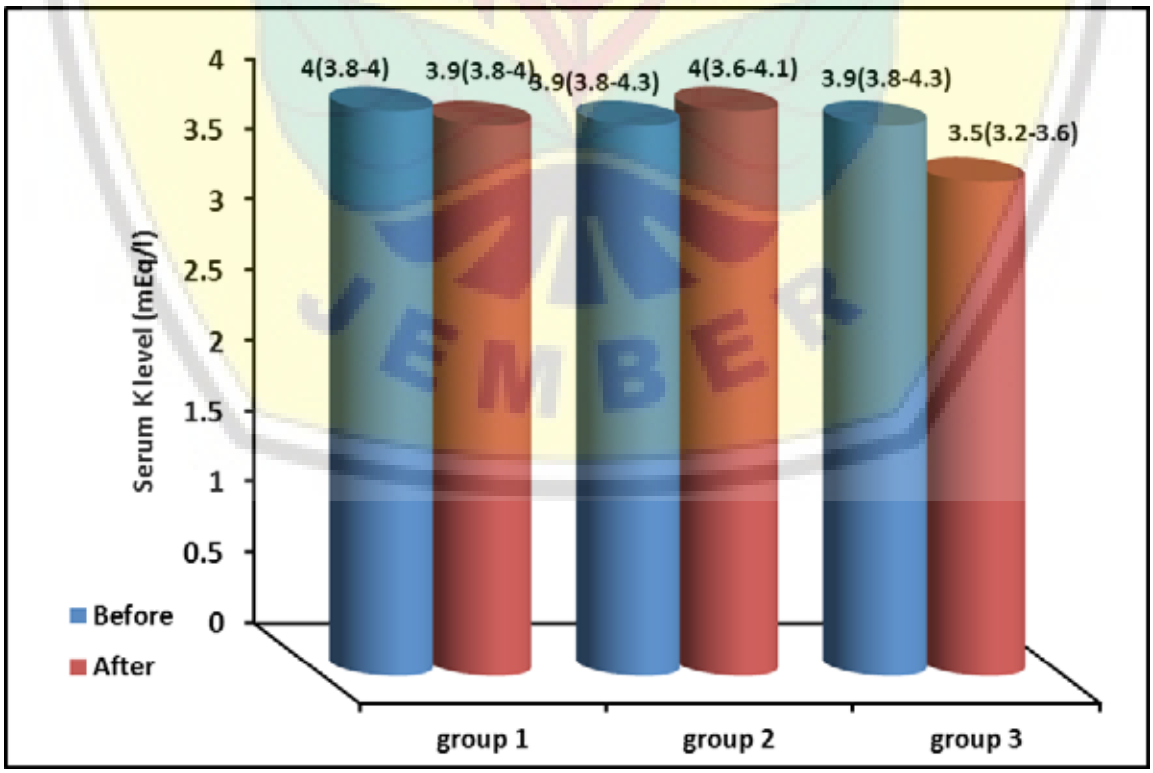

Fig. 1: Serum K level before and after patient enrollment in the study in group 1, 2 and 3 Data are presented as Median (interquartile range IQR)

Table 4: Changes in SBP and DBP before and after patient enrollment in the study. Data are represented as median (interquartile range IQR)

Group No.	SBP (mmHg) before enrollment in the study	SBP(mmHg) after enrollment in the study	P-value	DBP (mmHg)before enrollment in the study	DBP (mmHg) after enrollment in the study	P-value
1	115(100-120)	120(100-120)	0.094	85(70-85)	85(70-85)	0.125
2	125(100-125)	125(110-125)	0.060	75(70-80)	80(70-85)	0.109
3	120(100-120)	140(130-140)	0.003	80(70-80)	95(80-100)	0.008

Discussion

Regarding liquorice efficacy, the use of liquorice capsules resulted in no benefits on blood and sputum eosinophilic % reduction when compared to the reduction in the placebo group. The lack of effect may be due to the low doses used in our study, so, higher doses may be required to achieve a significant effect.

Comparing the pulmonary function improvement in group 2 and 3 to that of group 1 revealed that there was a significantly higher improvement in FVC% and in FEV_1% when compared to the placebo group (group 1). These results come in agreement with a study on 18 asthmatic patients which revealed a significant improvement of FEV_1% and FVC% after 3 weeks of treatment with liquorice [14].

The use of liquorice capsules in group 2 and 3 resulted in a significant improvement in ACT score when compared to that of group 1. These results can be supported by a study on the effect of aqueous liquorice extract on cough in mice as liquorice significantly decreased the frequency of cough in mice [15].

The use of liquorice capsules in group 2 resulted in no change in both SBP and DBP. These results are in agreement with a study on the safe dose of glycyrrhizin which demonstrated no adverse effects with a dose of 217mg daily [7]. However, in group 3, there was a significant elevation in both SBP and DBP and these results are consistent with the study mentioned above [7] on the safe dose of glycyrrhizin. Regarding serum K level in group 2 ,there was no significant change in serum K level. These results come in agreement with a study on 15 healthy volunteers who received pure liquorice extract equivalent to 250mg glycyrrhizin daily for 2 months with no significant change in serum K level [16]. However,in group 3, there was a highly significant reduction in serum K level. These results come in agreement with the case report of the patient who took glycyrrhizin 280mg daily and after two months, he suffered from hypokalemia and the K level was normalized after stopping glycyrrhizin [17].

Conclusions

The aqueous liquorice extract capsules significantly improved pulmonary function and ACT score in asthmatic patients at a dose equivalent to 200 and 300 mg glycyrrhizin daily and the dose of liquorice extract equivalent to 200mg glycyrrhizin daily was safe, however, increasing this dose resulted in a significant increase in BP and a significant reduction in the serum K level.

Funding: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Conflicts of Interest: There were no conflicts of interests.

Ethics Approval: All procedures performed in our study were in accordance with the ethical standards of the ethics committee in El Minia University Hospital that followed the International Conference on Harmonization - Good Clinical Practice (ICH-GCP) guidelines (Registration No.80-11/2018) and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. The trial was explained to each subject and his or her consent was obtained.

Protective Effect of Vitamin E Against Hepato-nephrotoxic Oxidative Stress Induced by Isoprinosine Toxicity

Gamal E.A.M. Shams[1], Ahmed A. Said[1], Nagah E.M. Omar[1], Ahmed M. Lotfy[2]

[1]Prof., Pharmacology Department, Faculty of Veterinary, Zagazig University, Egypt,
[2]Pharmacist in the Directorate of Health Affairs

Abstract

Isoprinosine was approved that it had hepatic and renal disorder in rabbits. This review covers key studies of protective effects of vitamin E (18.7 mg/kg P. O.) against isoprinosine (163.3 mg/kg P. O.) toxicity for 21 days when vitamin E was co-administered with isoprinosine. Blood samples were collected and the protective effect of vitamin E onbiochemical constituents in serum such as liver injury biomarkers as serum ALT, AST and ALP, kidney injury biomarker as serum creatinine and urea and oxidative stress biomarkers such as serum SOD, GPX and MDA. The obtained results indicated that vitamin E has protection effects through prohibiting the raise in liver and kidney injury biomarkers and oxidative stress biomarkers.

Keywords: *Isoprinosine, Vitamin E, Liver and kidney function and Antioxidant enzymes.*

Introduction

Isoprinosine is an immuno-modulatory antiviral drug that has been licensed since 1971 in several countries worldwide. It has beneficial clinical effects in several diseases and infections including mucocutaneous herpes simplex infections, sub-acute sclerosing panencephalitis, genital warts, influenza, zoster and type B viral hepatitis([1]). Several clinical trials established safety profile of isoprinosine as([2]) who found isoprinosine appeared to have a relatively low degree of both acute and chronic toxicity in both rodent and non-rodent species. Isoprinosine seem to be highly toxic for chicken embryos([3]). Isoprinosine, in higher doses, caused excessive release of enzymes and generation of free radicals which caused lung injury and worsening symptoms of bovine respiratory disease (BRD)[(4)].

Antioxidants have been defined as substances that prevent the formation of reactive oxygen species (ROS) or other oxidants, scavenge them or repair the damage they cause. Antioxidant defenses act as a balanced and coordinated system and each relies on the action of the other ([5]). Antioxidant defenses consist of low molecular mass antioxidant such as vitamin E and enzymes e.g. SOD, CAT and GPX ([6]).

Vitamin E is the most important lipid phase antioxidant ([7]). Vitamin E is an important antioxidant in biological system that diminishes the peroxidation of un-structural lipids by chain breaking free radical (FR), thus it contributes to the stability of cellular membranes([8]).

The aim of the work: This study examines protective effects of vitamin E against isoprinosine for 21 days. Blood samples are collected and the protective effects of vitamin E on liver, kidney and antioxidant enzymes are examined through measuring some constituents in serum as ALT, AST, ALP, creatinine, urea, SOD, GPX and MDA.

Drugs and chemicals: Isoprinosine 50 mg/kg (Ip50, reference standard) ([9]) was supplied by Newport pharmaceutical. Vitamin E (vitamin E 400 mg capsule once daily) was supplied by PHARCO pharmaceutical. The human dose of isoprinosine and vitamin E converted to rabbit dose (163.3 mg/kg P. O.) and (18.7 mg/kg P. O.) respectively ([10]).

Animals: A total of twenty (40) Newzealand white

rabbits of 2-3 months old and weighing about 1800-2000 gm were used in the work. The rabbits were obtained from laboratory Animal Farm, Faculty of Veterinary Medicine, Zagazig University. All animals were kept under observation for two weeks for acclimatization to the laboratory environment before starting the experiments.

Ethical Clearance: The experimental animals were managed according to the management standard. The experimental study was approved by the committee of Animal Welfare and Research Ethics Faculty of Veterinary Medical Zagazig University, Egypt.

Experimental design: Rabbits randomly distributed into 4 major groups. 1st group was left non-treated, 2nd group was treated by isoprinosine for 21 days, 3 rd group was treated by vitamin E for 21 days and 4th group was treated by oral co-administration of isoprinosine and vitamin E for 21 days.

Preparation of serum sampling: Blood samples were collected and left to clot for 30 minute at room temperature, then centrifuged at 3000 rpm for 15 min. The top layers of serum were collected then stored at -20˚C and defreezed just before use.

Biochemical markers of liver injury: Determination serum ALT and AST were done according to ([11]). Determination of serum ALP was done according to ([12]).

Biochemical markers of kidney injury: Determination serum creatinine was done according to ([13]) and urea according to ([14]).

Biochemical markers of antioxidant activity

Determination serum SOD, GPX and MDA were done according to ([15]) and ([16]) respectively. Statistical analysis

The obtained data in the present study were statistically analyzed using the computer program (SPSS version 15 for Windows) and comparison were made using one way ANOVA. Post hock test was carried which considered statistically significant when P< 0.05 ([17]).(mean± S.E), (N=10).

Results

Effect of co-administration of isoprinosine and vitamin E on biochemical markers of liver injury (U/L) of rabbits at 7th, 14th and 21th day post

Oral co-administration of isoprinosine andvitamin E produced a significant decrease in serum ALT at 7th, 14th and 21th day post treatment (57.63 ± 1.883, 42.66 ± 1.309 and 34.00 ± 1.469) when compared with isoprinosine alone (64.38 ± 2.89, 54.75 ± 3.603 and 44.01± 3.938).

Oral co-administration of isoprinosine with vitamin E produced a significant decrease in serum AST at 7th and 14thday post treatment (43.43 ± 3.573 and33.76 ± 4.144) when compared with Isoprinosine alone (54.57± 3.798 and 45.62 ± 4.001respectively).

Oral co-administration of isoprinosine with vitamin E produced high significant decrease in serum AST at 21th day post treatment (26.42 ± 1.601) when compared with isoprinosine alone (39.53 ± 1.007).

Oral co-administration of isoprinosine with vitamin E produced high significant decrease in serumALP at 7thday post treatment (95.16 ± 1.456) when compared with isoprinosine alone (101.63 ± 0.779).

Oral co-administration of isoprinosine and vitamin E produced a significant decrease in serum ALPat 14th and 21th day post treatment (86.74 ± 0.792 and 82.39 ± 0.532respectively) when compared with isoprinosine alone (90.61 ± 1.464and 87.02 ± 1.426respectively).

Effect of oral co-administration of isoprinosine and vitamin E on serum biochemical markers of kidney injury (mg/dl) of rabbits at 7th, 14th and 21th day post treatment:

Oral co-administration of isoprinosine and vitamin E produced high significant decrease in serum creatinine at 7th, 14th and 21thday post treatment (1.86 ± 0.076, 1.49 ± 0.036and 1.17 ± 0.084 respectively) when compared with isoprinosine alone (2.10 ± 0.061, 1.82 ± 0.046and 1.53 ± 0.049respectively).

Oral co-administration of isoprinosine and vitamin E produced high significant decrease in serum urea at 7th day post treatment (66.97 ± 2.672) when compared with isoprinosine alone (77.42 ± 1.193).

Oral co-administration of isoprinosine and vitamin E produced a significant decrease in serum urea at 14th and 21th day post treatment (54.37± 1.822 and 40.87 ± 1.286) when compared with isoprinosine alone (60.63± 1.522 and 46.43± 1.993).

Effects of oral co-administration of isoprinosine and vitamin E on serumbiochemical markers of

antioxidant activity (U/L) of rabbits at 7th, 14th and 21th day post treatment: Oral co-administration of isoprinosine andvitamin E produced high significant increase in serum SOD at 7thday post treatment (2.33 ± 0.05) when compared with isoprinosine alone (1.08 ± 0.015).

Oral co-administration of isoprinosine and vitamin E produced a significant increase in serum SOD at 14th and 21th day post treatment (3.03 ± 0.043 and 3.28 ± 0.102 respectively) when compared with isoprinosine alone (1.82 ± 0.071 and 2.10 ± 0.95 respectively).

Oral co-administration of isoprinosine and vitamin E produce high significant increase in serum GPX at 7th and 14thday post treatment (99.67 ± 2.126 and98.97 ± 2.043 respectively) when compared with isoprinosine alone (74.90 ± 2.892 and82.07 ± 3.718respectively).

Oral co-administration of isoprinosine and vitamin E produce a significant increase in serum GPX at 21th day post treatment (98.53 ± 2.806) when compared with isoprinosine alone (91.20 ± 2.739).

Oral co-administration of isoprinosine and vitamin E produced high significant decrease in serum MDA at 7thday post treatment (27.73 ± 1.399) when compared with isoprinosine alone (33.40 ± 1.44).

Oral co-administration of isoprinosine with vitamin E produce a significant decrease in serum (MDA) at 14th and 21th day post treatment (22.83 ± 1.488 and 17.53 ± 1.496respectively) when compared with isoprinosine alone (27.15 ± 1.773 and 22.83 ± 1.774respectively).

Discussion

Vitamin E is one of the most important antioxidant drugs due to its hepato-nephro protective properties as reported by researches as ([18]). This study demonstrated the hepato-nephroprotective effect of vitamin E against isoprinosine toxicity. For liver biomarkers, we found that isoprinosine elevated serum alanine aminotransferase, serum aspartate aminotransferase, serum alkaline phosphatase which agreed with many researchers as ([19]).

For kidney biomarkers, we found that isoprinosine elevated serum of creatinine and serum urea which agreed with many researchers as ([20, 3]).

For antioxidant enzymes, we found that isoprinosine decreased superoxide dismutase and glutathione peroxidase and increased malondialdehyde which agreed with many researchers as ([21]).

According to the pervious results, we think to overcome hepato-nephrotoxic oxidative stress which induced by isoprinosine by use antioxidant agent like vitamin E. Co-administration of isoprinosine and vitamin E led to improve serum ALT, AST, ALP, creatinine, urea, SOD, GPX and MDA. This is in harmony with many researchers as ([22, 23, 24]) who used vitamin E with cytotoxic agents as carbon tetrachloride and prednisolone, respectively. More than administration of vitamin E in some diseases led to improve the illness by improving biomarkers after worsen by these diseases as liver diseases and pulmonary TB diseases, respectively([25, 26]).

There are many researchers who proved and explained the protective effects of vitamin E stabilizing membrane against phospholipase A, free fatty acids and lysophospholipids([27]), diminishing the peroxidation of unstructured lipids by chain breaking free radical([8]) acting against oxidative stress by using antioxidant defense system to control damaging species as reactive oxygen, nitrogen and chlorine species([6]), decreasing lipid peroxidation radicals before they attack the membrane lipid([28]) acting as a lipid soluble antioxidant so preventing normalized ROS damage in polyunsaturated fatty acids a membrane-stabilizing agent so acting against phospholipids damage and breaking the antioxidant chain so preventing ROS-produced cell membrane([29]).

Conclusion

It could be concluded that isoprinosine has hepatic and renal disturbance in rabbits; the co-administration of isoprinosineand vitamin E showed better results than isoprinosine alone. As vitamin E has protective effects against hepatic and renal disturbance, which may attribute to decrease the harmful effects of isoprinosine by in habiting free radical formation and by restoration of antioxidant systems.

Antibacterial Activity and Morphology Changes of Propionibacterium ACNES After Giving Curcuma Xanthorrhiza Extract

Halimatus Zahrah[1], Arifa Mustika[2], Debora Kartuti[1]

[1]Graduate Program, Faculty of Medicine, University of Airlangga, [2]Graduate Program, Faculty of Medicine, University of Airlangga, Surabaya

Abstract

The use of antibiotics considered to have raised suspicion of resistance to P. acnes as a causative agent for acne so that it encourages various parties to develop anti-inflammatory preparations that can be given topically or systemically. Curcuma xanthorrhiza Roxb. has the main compound xanthorrizol which is considered potential for development as an antibacterial. The research purpose was to determine minimum inhibitory concentration and minimum bacterisidal concentration as well as morphology changes of P. acnes after giving Xanthorrhiza Curcuma Roxb. extract. Research design was experiment, with sample of P. acnes in the form isolates stock culture (ATCC® 11827™), which further grown on MHA media. Concentration extract was 6.25 µg/ml, 12.5 µg/ml, 25 µg/ml, 50 µg/ml and 100 µg/ml. Research result that concentration 25 mg/ml as the MIC, while the 50 µg/ml as MBC. P. acnes bacteria that were exposed has morphologic change of the cell wall due to shrinkage and a rough rough their cell walls are destroyed so that the cytoplasm out and looked like a melted. From this result indicated that extract of Curcuma xanthorrhiza Roxb. has an antibacterial effect against P. acnes bacteria in vitro.

Keywords: *Antibacterial, Acne vulgaris, Curcuma xanthorriza Roxb., SEM, TEM.*

Introduction

The management of Acne vulgaris were divided by degree of severity, in mild acne light therapy is given only topical treatment including retinoal acid or benzoyl peroxide. Treatment of moderate and severe acne can be added using the oral therapy with doxycycline or other antibiotics, but in pregnant women and breast-feeding is recommended to give antibiotics erythromycin.[1] Tetracycline is widely used for inflammatory acne, but tetracycline left since terhdap P. acnes resistance rates are quite high. Tetracycline derivative is doxycycline and minocycline replacing tetracycline as a first-line oral antibiotic therapy, but erythromycin also restricted only in pregnant women because it easily happens resistance of P. Acnes.[2]

The prevalence of antibiotic-resistant P. acnes vary in different countries. High prevalence occurs in various European countries with a resistance erythromycin/ clindamycin ranged between 45% -91% and tetracycline resistance from 5% to 26.4%. The prevalence of antibiotic-resistant P. acnes in the Asian region there is a big difference, for example in Japan, erythromycin or clindamycin resistance rate of only 4% and tetracycline or doxycycline only 2%. While in Korea, a recent study found only one of the 33 strains (3.2%) isolates were resistant to clindamycin in this case because of antibiotic-resistant P. acnes has not progressed quite well in Korea, while the results of research in Indonesia P. acnes resistance to the antibiotic tetracycline 12.9%, 45.2% erythromycin and clindamycin 61.3% whereas in doxycycline and minocycline there was no resistance.[3]

The use of topical antibiotics trigger only limited resistance in the treated area, but the use of oral antibiotics may develop resistance to all areas of the body. Based on a systematic review of 50 clinical trials on the use of topical antibiotics, there is a decrease in the effectiveness of both erythromycin topical acne lesions inflammatory and non-inflammatory allegedly linked to the development of antibiotic resistance of P. acnes.[4]

The emergence of the alleged resistance to the use of antibiotics for the treatment of acne encourage various parties to develop preparations of anti-inflammatory can be administered topically or systemically, for example, topical nicotinamide to treat acne inflamed mild and moderate, while benzoyl peroxide in the ointment anti Acne vulgaris regarded as topical disinfectants that are sold freely and the most effective in the treatment of Acne vulgaris former stains. Therefore we need an alternative drug substance as an antibiotic against P. acnes on the treatment of Acne vulgaris problem primarily derived from natural materials to minimize side effects.[5]

The content of the antibacterial potential possessed by xanthorrhiza Curcuma Roxb. are flavonoids. Flavonoids are phenolic compounds derivatives can cause disruption of the integrity of bacterial cell walls and membranes that can be seen from the changes in the size and morphology of bacterial cells.[5]The content of the active ingredient in xanthorrhiza Curcuma Roxb. potentially as an antimicrobial make a lot of interested parties to use it as a topical treatment of acne. When this has been circulated freely various types of cream Temulawak questionable results of clinical trials as well as the legality of the drug and food watchdog BPOM so that a MIC and MBCproduct is not yet reliable.

Based on this background set research objectives are: to know the minimum inhibitory concentration and minimum bactericidal concentration as well as morphology changes of Propionibacterium acnes after giving Curcuma xanthorriza Roxb. extract.

Research Method

Research design: This type of research used in this study is the experimental method (experimental), with post test only control group design.

Population and Sample: Samples was Propionibacterium acnes in the form of stock culture isolates American Type Culture Collection (ATCC) by the name of Propionibacterium acnes (ATCC® 11827 ™) were obtained from a laboratory in the field for later grow in media Mueller Hinton Agar (MHA) and incubated at 35o C. for 24 hours with the condition of the carbon dioxide concentration of 5% -10%.[6] Number of replication based on the number concentration of treatment is 4 replications.

Research Variable: The independent variables were the concentration of extract of *Curcuma xanthorrhiza Roxb.* with each concentration of 6.25 µg/ml, 12.5 pg/ml, 25 pg/ml, 50 pg/ml and 100 pg/ml.[7] The dependent variable in this study tends antibacterial activity as measured by minimum inhibitory concentration (MIC) and Minimum Baterisidal Concentration (MBC) in MHA media as well as changes in the structure of cell walls of bacteria P. acnes.

Research Procedure: The procedure of making MHA media containing ethanol extract of *Curcuma xanthorrhiza Roxb.* various concentrations is start with made concentration of stock solution used was 1.000 mg/mL were then added MHB with serial dilution concentrations used were 100%, 50%, 25%, 12.5%, 6.25% and 0%.The solution was incubated at 25 ° C for 24 hours.A solution of each flask is then poured into a petri dish MHA at each containing 10 mL. The media has done as much as P acnes bacteria inoculation 1,5x104 CFU to each surface MHA medium in a petri dish with mayo method.Test media were incubated at 35°C for 24 hours prior to observing.

Observations using SEM and TEM to determine the effect of extracts on P. acnes were carried out by identifying changes in the structure of P. acnes cell walls by observing the size (diameter) of P. acnes bacterial cells, the state of P. acnes bacterial cell walls and the number of P. bacterial cells. acnes field of view. SEM and TEM tests were performed on MHA test media from concentrations of 0 µg/mL (Control) and 25 µg/mL (P3).

Results

Determination of MIC was done by identifying the lowest concentration of the extract was able to inhibit the growth of bacteria, wherever the minimum Baterisidal Concentration (MBC) were assessed by lowest concentration which showed no bacterial growth on MHA.

Table 1. Minimum Inhibitory Concentration (MIC) Result

R	Concentration Extract					
	100 µg/ml	50 µg/ml	25 µg/ml	12.5 µg/ml	6.25 µg/ml	Control (0 µg/ml)
R1	-	-	+	++	++	++
R2	-	-	+	++	++	++
R3	-	-	+	++	++	++
R4	-	-	+	++	++	++

Table 2. Minimum Bacterisidal Concentration (MBC) Result

R	Concentration Extract					
	100 µg/ml	50 µg/ml	25 µg/ml	12.5 µg/ml	6.25 µg/ml	Control (µg/ml)
R1	-	-	+	++	++	++
R2	-	-	+	++	++	++
R3	-	-	+	++	++	++
R4	-	-	+	++	++	++

Information:

Negative (-) : No growth of bacteria *P acnesin*the MHA media

Positive (+) : No growth of bacteria *P acnes* in the MHAmedia

Positive (++) : No growth of bacteria *P acnes* in the MHA media with high quantity

Based on the above results showed that the extract of *Curcuma xanthorrhiza Roxb.* has antibacterial activity against P acnes bacteria on MHA with extract concentration 25 µg/ml, 12.5 pg/ml and 6.25 pg/ml as indicated by the growth of bacteria on inoculated MHA P acnes as well as the MHA and MHB the concentration control also contained P acnes bacteria growth in considerable amounts. Based observations concluded that concentration of 25 µg/ml as MIC.

Based on table 2 can be seen on the replication of R1-R4 on MHA medium containing the extract concentration of 50 µg/ml and 100 µg/ml did not seem the growth of P acnes so the concentration of 50 µg/ml concluded as MBC value.

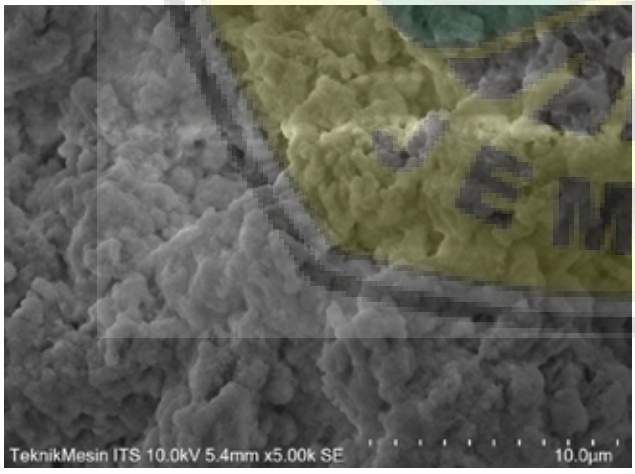

Figure 1. Scanning Electron Microscopy (SEM) Result of P. acnes that are not exposed to Curcuma xanthorrhiza Roxb.extractat 5000x Magnification

*Curcuma xanthorrhiza Roxb.*at concentration 0% (K) and 25% continued with the examination using a Scanning Electron Microscopy at a magnification 5000-20000 times to describe the changes in the structure of cell walls of bacteria P. acnes.

Based on the observations above shows that the P acnes bacteria in the control group looks solid with the conditions of the bacterial cell wall intact.

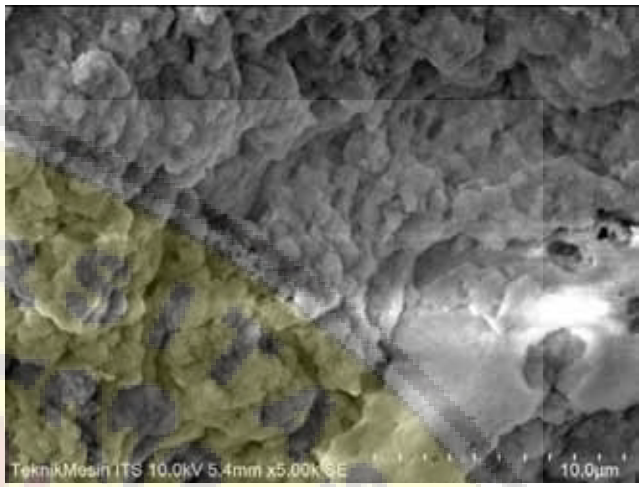

Figure 2. Scanning Electron Microscopy (SEM) Result of P. acnes that are not Exposed Curcuma xanthorriza Roxb. withconcentration of 25% at 5000x magnification

The observation of P acnes bacteria cell walls exposed xanthorrhiza ethanol extract of Curcuma Roxb. with a 25% concentration of morphological changes occur in the form of coarse cell wall due to shrinkage as well as their cell walls are destroyed so that the cytoplasm out and looked like melted.

Transmission Electron Microscopy were carried out at magnification starting from 1.0 µm - 500.0 nm to find out a description of the changes in the structure of the cell wall of P.acnes bacteria in more detail as follows:

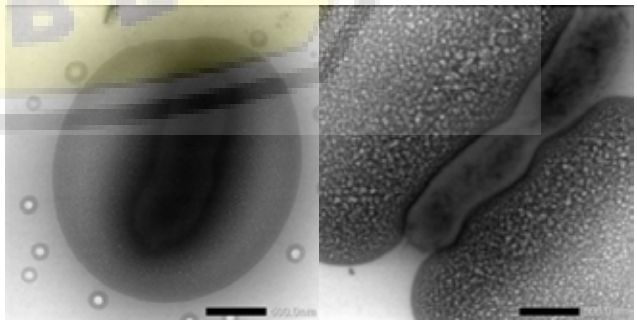

Figure 3. Transmission Electron Microscopy (TEM) Results of Non-Expossed P.acnes with Ethanol Extract Curcuma xanthorrhiza Roxb.at 500 nm magnification

Based on observations at a 500 nm magnification above the visible cell wall intact, the cytoplasm is tightly packed with the cell nucleus in the middle.

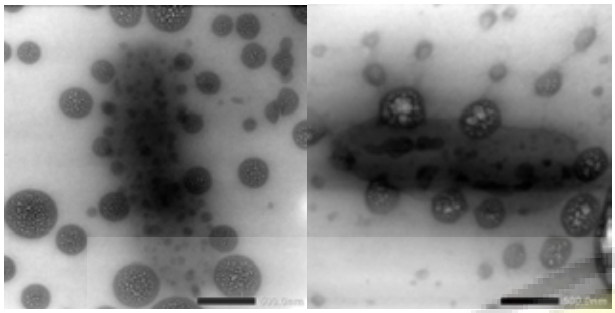

Figure 4. Micrographic Transmission Electron Microscopy (TEM) P.acnes Exposed to Curcuma xanthorrhiza Roxb. extract with a concentration of 25% at 500 nm magnification

The observation of the cell wall of P.acnes bacteria at TEM magnification of 500 nm appeared to damage the cell wall and so that the cytoplasm appeared granulated and became more fluid seen from the cytoplasm color which was more transparent than in the control sample.

Discussion

Research results indicate that extract of *Curcuma xanthorrhiza Roxb.*have antibacterial activity against the growth of P acnes that is a type of gram-positive bacteria. These results are consistent with research conducted by Diastuti which shows extracts of *Curcuma xanthorrhiza Roxb.* containing α-curcumene, xanthorrizol and monoterpenes have significant antibacterial effect against gram-positive bacteria Bacillus subtilis and Staphylococcus aureus and gram-negative bacteria Pseudomonas aeruginosa with MBC value of 15.6µg/mL either the extract with acetone and n hexane extraction.[8] Xanthorrhiza Curcuma Roxb antibacterial effect. weak against gram-negative bacteria Shigelladysenteriae, and Vibrio cholerae, and does not have an antibacterial effect against gram-negative bacteria Escherichia coli, Enterobacteraerogenes and Salmonella thypi.

Other research by Adilashowed that extracts of Curcuma provides third-microbial inhibition test against Candida albicans (13.07 mm), Staphylococcus aureus (15.75 mm) and Escherichia coli (31.56 mm). MIC and MBC fresh ginger rhizome extract against E. coli respectively 12.5% and 25%. Whereas in C. albicans and S. aureus fresh ginger extract does not kill the bacteria test.[9] The difference value caused by E.coli cell wall structure that different from S. aureus and C. albicans, where E. coli although belonging to gram-negative bacteria have a cell wall composition intricate yet E.coli have an outer membrane protein on wall cell that serves as the entry and exit channels of the active compound, so that the active compounds in ginger will easily enter and damage the enzyme activity of cells that cause damage to cells of E. coli.[10] Whereas in C. albicans despite belonging to gram-positive bacteria, but the formation of chlamydospores cell structure that forms the walls thicker so difficult to be penetrated by the antimicrobial compound.[11]

SEM examination of the P acnes bacteria exposed by Curcuma xanthorrizaconcentration of 25µg/ml (P3), shows the P acnes bacteria cells undergo morphological changes such as the onset of cell diding rough due to shrinkage as well as their cell walls are destroyed so that the cytoplasm out and looked like a melted. This caused by the content xanthorrizol also caused by the content of curcumindmilikixanthorriza Curcuma Roxb. The results of another study by Tyagi reported that curcumin has antibacterial against all test bacteria from both Gram-positive and Gram-negative and killing power increases with the dose and time of incubation. Curcumin killing power 100% of the test bacteria at a dose of 100 µMcurcumin even when tested on bacteria with a higher density (106 CFU/ml). While looking at the reported observation under a change in the surface roughness and the incidence curve of the cell wall. On incubation with higher doses cause cell wall leakage.[12]

Xanthorriza extract of Curcuma Roxb. has a unique antimicrobial compound that is xanthorrizol not owned by rhizome of Curcuma else though content is only in very small quantities. This is consistent with the statement Hansel[13] are compounds in ginger xhantorrizol ≥6% while turmeric ≥3%. Xanthorrizol compound is the main antibacterial active compounds found in ginger rhizome antibacterial activity of xanthorrizol have good stability to heat, which at high temperatures between 60-121°C. Fatmawati research results also found that that the content xanthorrizol able to inhibit the growth of Streptococcus mutans and S. aureus.[14]

Response inhibition of bacterial growth resulting xanthorrhiza Curcuma Roxb. affected by the active compounds contained therein such as essential oils, alkaloids, flavonoids, tannins, kurkuminoid and terpenoids.[15] Flavonoid compounds capable of destroying the cell wall, causing cell death. Flavonoids can also inhibit the formation of proteins that inhibit

bacterial growth. In addition to flavonoid content of other compounds such as tannin can also damage the cell membrane. Tannin can damage the formation of mildew conidia. The content of other compounds such as alkaloids in the rhizome of Curcuma xanthorriza Roxb. able to denature proteins that damage the activity of the enzyme and cause cell death.[16]

Cikrici et al., adds that curcuminoid antibacterial activity against bacterial activity by inhibiting the activity of the enzyme cyclooxygenase-2 (cox-2) which converts arachidonic acid to prostaglandins that cause taste sakit.Curcuminoid the phenolic compounds can also inhibit the growth of denature and bacteria by damaging the cell membrane so that the cell metabolism will be disturbed.[17]

Conclusions

Giving Curcuma xanthorrhiza Roxb extract. has an antibacterial effect on P.acnes bacteria in vitro which is thought to be due to the content of essential oils (Xanthorrizol), Curcuminoids and Flavonoids. Extract concentration 25 mg/ml is the minimum level that can inhibit (MIC) the growth of P acnes through liquid dilution, while the minimum concentration that can kill (MBC) P acnes is 50 µg/ml. P acnes bacteria were exposed to ethanol extract of *Curcuma xanthorrhiza Roxb.* morphologic change of the emergence of the cell wall due to shrinkage and a rough rough their cell walls are destroyed so that the cytoplasm out and looked like melted

Role of Quality of Care to the Contraceptive Use in Asia and Africa: A Systematic Literature Review

Hariyanti[1], Kemal N. Siregar[2], Sabarinah B. Prasetyo[2], Ali Sungkar[3]

[1]Doctor of Public Health Study Program, [2]Department of Biostatistics and Population Studies, Faculty of Public Health, Universitas Indonesia, [3]Department of Obstetrics and Gynecology, Faculty of Medicine, Universitas Indonesia

Abstract

Background: The modern contraceptive use is decreasing and the prevalence of using Long Acting Contraceptive System (LACS) is low in Indonesia;all Family Planning targets are not achieved. This indicates the low family planning services quality. The purpose of this study is to identify publication results about services quality that could increase the contraceptive use's prevalence in developing and developed countries. **Method**: This study uses Systematic Literature Reviewunder electronic data from ProQuest, Ebsco, PubMed, SpringerLink and Google Scholar. **Results**: The obtained publication of articles is still limited, in terms of number and geographical distribution, namely 9 articles from Africa and 2 articles from Asia. The review results showed the contraceptive user's range from 11.3% to 86.5%. The family planning services quality can increase the contraceptive use. In this study, most of those articles examine the providers' competenceand information provision to clients. The review results explained that training of injection and implant contraceptive services by community health workers had a positive impact on family planning programs. The review also revealed that the low counseling skill by providers is a barrier to the contraceptive services. **Conclusions**: In the last ten years in the world, it was found that the family planning services qualitycancomprehensively improve contraceptive services. In Indonesia, there is no publication on this topic, thus it needs a research to examine the family planning services quality through the midwifery and family planning field workercompetence review as well as the information provision by providers.

Keywords: *Contraception, service quality, choice of method, information, competence, counseling, provider-client relationship, follow-up, program integration.*

Introduction

The world's Maternal Mortality Rate (MMR) in 2015 was 216 per 100,000 live births. The MMR in developed countries is only 12 per 100,000 live births, while in developing countries the MMR reaches 239 per 100,000 live births[1]. The contraceptive use among women with unmet need is estimated to reduce the mortality by almost a third[2]. However, the contraceptive use in developing countries, especially effective method, is still relatively low[3].

MMR in Indonesia reaches 305 per 100,000 live births[4]. It is far from targets under Millennium Development Goals (MDGs). Causes of Indonesia's maternal death dominated by direct causes, such as bleeding, hypertension in pregnancy and infection. Maternal death will not occur if the pregnancy can be prevented and controlled[5].

One main pillar in reducing the MMR is preventing risky pregnancy through Family Planning. However, the success of Indonesia's family planning services is stagnant. The Indonesia's prevalence of

e-mail: yantihariri80@gmail.com

modern contraception use shifted, where the modern contraception use decreased and conversely, the use of the traditional contraception increased. The 2017 Indonesia Demographic and Health Survey (IDHS) results showed the modern contraceptive use is 57.2% and the use of the traditional contraception is 6.4%[6].

The contraceptive use influenced by the service quality. The service quality is defined through six basic elements: choice of method, information for clients, providers' competence, interpersonal relationship, mechanisms to encourage sustain ability and integrated services[7,8]. It can be measured at the levels of policy, service delivery or client[9]. Thus, it is necessary to examine the quality of contraceptive service elements with the most substantial role in increasing the contraceptive use.

Method

This study uses the Systematic Literature Review method through four stages, namely identification, screening, eligibility and inclusion. The inclusion criteria in this literature search: 1) the subject consists of married women of family planning acceptors; 2) the research outcome is the scope of the contraceptive use; 3) articles in form of research based on keywords;and 4) articles published in 2009-2019; and 5) articles in English and Indonesian. Its keywords are service quality and contraceptive use.

The article search results using Preferred Reporting Items for Systematic Reviews & Meta-Analysis (PRISMA) instrument and a flow chart compiled based on the 2009 PRISMA checklist guidelines for the selected article. Based on the literature search results with systematic literature review techniques, there were 874 articles with keywords of contraception, coverage, quality and sustainable. Through duplicate selection and open access, there were 298 articles, by removing 565 articles (515 were not according to PICOS, 23 in form of systematic review/study protocol and 27 in form of books and reports), thus the remaining 11 articles were in full text which met all requirements to be synthesized.

Results

Characteristics of Articles: The synthesized articles found 11 articles, respectively 9 from Africa and 2 from Asia (India and Pakistan), eligible to be examined. Majority of 7 articles were published in the last 5 years.

Articles obtained using various research method, which 6 with intervention study, 3 with cross-sectional study, 1 with mixed study method and 1 with qualitative study. This systematic literature review traces all types of studies aimed at exploring various aspects of the family planning services quality that can increase the contraceptive use.

Family Planning Services Quality: Systematic literature review results indicated that an important element of the service quality is the providers' competence. of the 11 articles found, 54% of them reviewed the providers' competence. In Ethiopia, health extension workers or Health Extension Workers (HEWs) trained to be able to provide Implanon services to the community, which previously only served as health extension workers and provided non-clinical contraceptive services such as pills and condoms. Review results indicated the transfer of duties to health educators for the improvement contribution of implantable contraceptive services[11]. Likewise in Zambia and Congo, they also provide injection contraceptive services training to the Community Health Workers (CHWs) [12,13].

Efforts to increase competence also carried out by empowering the community through peer education and recruiting community members using the approach of the Community Based Distribution (CBD) to be able to well-inform about the contraception and to make referrals to family planning services at the community level [14,15]. The availability of community health workers at the village level significantly increases the contraceptive use [16].

In this review, it also revealed that the low IUD service occurred because in some countries there are restrictions on the authority of midwives and nurses to perform IUD contraceptive services, brought the reduced demand of IUD services and the loss of skills and confidence of providers[17].

The service quality aspects found in this review are counseling and providing information. The review results revealed that the low IUD request occurred because the officer did not offer IUD as a contraceptive option[17]. It also found that the exposure to messages about family planning at the individual or household levels can significantly increase the modern contraceptive use, but IEC activities at the village level do not affect the same[16].

Peer education programs aimed at dispelling myths and misperceptions about using the Long-Term Contraception Methodcan also increase the use of Long-Term Contraception Method[14]. In Pakistan, dismissal of myths and misconception about IUD can be done in health facilities, but private service sources are not motivated and reluctant to provide IUD services because of lacking counseling skills, Likewise, government programs are not equipped with trained staffs to promote IUDs[18]. Provision of detailed information to users can also have a significant influence on the method continuation rather than by merely providing information about alternative method and group counseling[19].

It also revealed that 6% clients receivedthe assistance in the selection of method prefer using contraception rather than the current contraceptive use. Furthermore, 10% clients treated very well by the providertend to use the contraception now compared to clients treated poorly. Clients who will re-use facilities and or recommend the same to others are 1.2 times tend to become current users compared to clients who will not return or recommend facilities to others [10].

Efforts to integrate family planning service componentswith infant immunization services have a positive effect on the modern contraceptive use in Rwanda[20].

Family planning coverage: Not all of the proportion of the modern contraceptive use in this systematic review found in selected journals. It is because this study also includes articles with qualitative approach that further explain factors or causes for not achieving the expected outcomes. The study results obtained a range of the contraceptive use from 11.3% to 86.5%.

Based on a study in India which analyzed the exposure to family planning messages, 86.5% of women aged 15-44 using family planning consisting of 78.3% with modern birth control and 8.2% the natural birth control[16].

Based on a study in Zambia intervened in CHW by practicing injection service skills, from 1,739 new family planning acceptors: 85% injection, 13% pill and 2% condom[12]. The same study in Congo by training 34 CHWs with a sample of 252 injecting acceptors stated that almost all acceptors were satisfied and would continue having injection with CHW services [13]. A study in Ethiopia which trained extension workers and carried out Implanon service assignments found that from 1,382,318 women who received contraceptive services, 92% used Implanon contraception[11]. Based on a study in Nigeria which recruited community members to become agents of family planning services, the contraceptive use, which was only 16%, increased to 37% after the intervention[15].

A study in Kenya through the study of service quality elements obtained 65% coverage of the use of modern method. Meanwhile a study in Rwanda which integrated components of family planning services with infant immunization found that early modern family planning was 49% and increased to 57% after the intervention[20].

Discussion

This systematic literature review has accessed many literature sources from various accredited journals. However, this review literature is limited to journals that can be accessed through on-line sites and do not access other literature categorized into gray materials.

In Indonesia, publications about the family planning services quality and the family planning use discovered more than 10 years ago. Most publications on this topic are in Africa and in Asia foundin India and Pakistan.

According to family planning coverage, the highest is in India of 86.5% and the lowest is in Lualaba of 11.3%. In Indonesia, the contraceptive use reaches 64%. Those figuresincreased in the use of traditional family planning, while the modern family planning decreased. It is an indicator of low family planning services quality in Indonesia[21].

In this study it was found that increasing the competency of CHWs was able to encourage the use of contraception. The definition of CHW by WHO[22] includes various public health cadres selected, trained and worked in their home communities. In Indonesia, CHW is equivalent to family planning field workerrunning national family planning programs at the village level, which the amount is still limited. Their job is to provide family planning information to the community, while those in charge in providing family planning services, especially injection and long-term contraception are health professionals such as midwives, nurses and doctors. This fact shows that the direction of development and the strategy ofFamily Planning Population in the National Medium Term Development Plan 2015-2019 in Indonesia has not been successful, which one of the strategies is to increase the number and

strengthen the capacity of family planning field workers and health services family planning services[23].

The review findings found limitations on the authority of midwives and nurses in giving IUD services. It is similar to Indonesia's situation that the authority of contraceptive services is governed in the Indonesian Ministerial Regulation of Health, which states that midwives have the authority to provide women's reproductive health and family planning services, limited to counseling on women's reproductive health and family planningand oral contraceptive services, condoms and injections. Midwives have the authority to provide services based on government assignments as needed, one of which is the provision of contraceptive services in the womb and subcutaneous contraceptives, which previously had received training and received certificates[24]. Based on the regulation, not all midwives may carry out IUD and implant services, while most service sources are midwives, especially independent practice midwives.

Other findingsin the family planning services quality in this review are importance of information provision and counselling. Research on efforts to improve the information provision to clients by providers carried out in Indonesia, but in recent times in 2005. The research aims to increase the client participation in family planning through community education and mass media[25].

Based on Indonesian conditions, providing information or counseling by providers is still rarely done. The 2017 IDHS results suggested that method information index is only 29%. This shows that the strategy in National Action Plan for family planning Services in 2014-2015 in Indonesia failed, where the strategy proposed was to increase availability affordability and family planning services quality through Information, Education and Communication (IEC) services and systematic counseling with one main programs is to ensure that the entire population can reach and obtain family planning services[26].

Conclusions

In the last 10 years (2009-2019),researches on the family planning services quality from Asia (India and Pakistan) and Africa are still limited. The findings showed that the comprehensive quality can increase the contraceptive use. The two most common quality are in aspects of providers' competence and information provision to clients.

In Indonesia, there is no publication on this topic, thus it is needed a research to assess the family planning services quality through midwifery and family planning field worker competence studies and the information provision by providers.

Conflict of Interest: The researcher stated that there was no conflict of interest in the implementation of this research.

Prognostic Value of Soluble Vascular Cell Adhesion Molecule-1 (SVCAM-1) in Children with Sepsis

Idham Jaya Ganda[1], Eva Faradianti[1], Dasril Daud[1]

[1]*Department of Pediatrics, Faculty of Medicine, Hasanuddin University, Makassar, South Sulawesi, Indonesia*

Abstract

Background: Sepsis is one of the major causes of mortality and morbidity in Children all over the world especially in industrial and developing country. Sepsis is identified by endothelial dysfunction due to excessive stimulation of cytokines and chemical mediator. VCAM-1 is an adhesion molecule which can predict the severity of the disease. This study aimed to identify sVCAM-1 as an outcome predictor (septic shock/not shock sepsis) in children with sepsis.

Method: This prospective cohort study was conducted in Pediatric Intensive Care Unit Wahidin Sudirohusodo hospital from September – December 2016. A total of 70 patients with sepsis were included. Plasma specimens were collected at admission, then the patients were being followed up if the patients get shock or not. The diagnosis of sepsis is using the International Pediatric Sepsis Consensus 2005 criteria. Serum sVCAM-1 was measured using Enzyme Linked Immunosorbent Assay technique.

Result: The initial level of sVCAM-1 was significantly increased in both groups, but higher in the septic shock group. Cut off point ≥100 ng/ml was obtained through the ROC, with sensitivity 100%, specificity 100%, positive predictive value 100% and negative predictive value 100%.

Conclusion: Initial level of sVCAM-1 can be used as an outcome predictor of children patients with sepsis and limit level ≥100 ng/ml is the most optimal cut off point as a prognostic value.

Keywords: *sVCAM-1, Sepsis, predictor, children, pediatrics.*

Introduction

Sepsis is an emergency situation which usually occure in Pediatric Care Unit. If this condition is not detected early and treated promptly, severe complications, including septic shock and multiple organ failure may occur and result in death[1)].

Corresponding Author:
Idham Jaya Ganda
Departement of Pediatrics, Faculty of Medicine, Hasanuddin, University, Makassar, South Sulawesi, Indonesia, erintis Kemerdekaan Km. 10 Tamalanrea, Makassar, 90245, Indonesia
e-mail: pediarics.uh@gmail.com
dhamjaya_spa@yahoo.co. Id

Sepsis is still one of the primary causes of morbidity and mortality in children around the world especially in industial and developing countries. In Indonesia, death rate caused by sepsis is 50-70% and even reach 80% if septic shock and organ disfunctional were included. In RSCM FKUI Jakarta, sepsis incidence in Pediatric Intensive care Unit (PICU) since January 2009 to March 2010 was 19.3%, with mortality rate approximately 54[2)]. In Wahidin Sudirohusodo Hospital, incidence rate of sepsis in Pediatric Intensive Care Unit since January 2015 to December 2015 was approximately 46% out of total 596 patients, 69% of the cases had septic shock with 35% mortality rate. Some experts believed that the incidence rate of sepsis will increase by 1.5% every year which means there would be 1 million additional cases per year by the end of 2020[3)].

Pathogenesis of sepsis reveals that there is a complex cellular activation, which is the release of

inflammation mediators, namely cytokine production, neutrophil activation, complemen activation, cascade coagulation and fibrinolitic system[2] Various cytokines such as TNF-α, IL-1, IL-6, leucotrien, thromboxane A2 as proinflammatory cytokine and IL-Receptor antagonist (IL-Ra), IL-4, IL-10 as anti-inflammatory cytokine triggered the inflamation process[4].

Increasing concentrations of adhesion molecules in the circulation occurs in patients with SIRS, sepsis and septic shock. sVCAM-1 is one of the adhesion molecules that can predict mortality and the gradual development of multiorgan failure in the lungs, liver and kidneys[5].

Based on the description above, it is necessary to do an approach to identify the influence and prognostic value from the biological parameter, such as VCAM-1, which is related to outcome of patients with sepsis and find the cut off point of sVCAM-1 level in pediatric sepsis patients. Study on the prognostic value of sVCAM-1 in pediatric patients with sepsis was never been done in Indonesia, especially in South Sulawesi. Thus, this study aims to analyze the prognostic value of the sVCAM-1 levels in children patients with sepsis.

Materials and Method

This study is an obsrvational study with prospective cohort approach which was conducted in Dr. Wahidin Sudirohusodo Hospital Makassar from September until Desember 2016 sample was collected. Blood samples were examined in the laboratory of Hasanuddin University Medical Research Center (HUM-RC).

The study population was patients with sepsis aged 1 month to 18 years hospitalized in pediatric intensive care unit (PICU) Dr. Wahidin Sudirohusodo Hospital Makassar. The population was diagnosed using the International Pediatric Sepsis Consensus 2005 and data of age, sex, nutritional status, vital signs (blood pressure, pulse, respiration rate, temperature and consciousness), clinical symptoms and routine laboratory tests was recorded. The samples are population who met the criteria of inclusion and exclusion. Exclusion criteria were including: 1) patient currently on a long term corticosteroids' medication; 2) patients who have trauma; 3) patients with burns; 4) patients with malnutrition; 5) patients with deficiency of immune system; 6) patients with malignancy; 7) patients wit septic shock. The blood sample of patients who met the inclusion criteria were extracted to assess for sVCAM-1 levels. During the treatment, patients were observed if sepsis develop into septic shock or do not develop. The final result of observation is the outcome (septic shock or without septic shock).

All the data obtained are recorded in the research data form and then grouped by the destination and type of data. Appropriate statistical method was used analyse the data, namely: 1) the univariate analysis; and 2) the bivariate analysis which includes: test Student's t, Mann Whitney Test, X2 (Chi square) or Fisher's Exact test, to assess the accuracy limit levels as a predictor, calculating the sensitivity, specificity, positive predictive value and predictive value negative (with CI 95%).

Results

Table 1 showed the characteristic of the sample. In the groups of patients with septic shock there were 56.8% boys and 61.5% girls. In the group of patients with septic shock there were 53% children with good nutritional status and 63.9% with malnutrition. In the group of patients with sepsis without shock there were 47% children with good nutritional status and 36.1% with malnutrition. Statistical analysis showed no significant differences in outcome based on the nutritional status with the value of $p = 0.353$ ($p > 0.05$). Median age of patients in septic shock group was 1.25 years and ranged from 0.08 to 16 years, while the other one was 2.4 years and a ranged from 0.50 to 15.42 years. Mann Whitney test results shows that there was no significant difference between the two groups with $p = 0.497$ ($p > 0.05$). The focus of most infections in this study was respiratory tract infections, followed by infection of the central nervous system, cardiovascular and gastrointestinal.

Median Levels of initial sVCAM-1 in septic shock group was 164.32 ng/ml and range from 101.09 to 520.68 ng/ml, sepsis without shock group median was 84.49 ng/ml and range from 53.34 to 99.39 ng/ml. Mann Whitney test results show that there were a very significant difference between the two groups with $p = 0.000$ ($p < 0.001$). (Table 2).

Comparative analysis of sensitivity, specificity, positive and negative predictive value for the levels of initial sVCAM-1 in every cut off point (98 ng/ml, 99 ng/ml, 100 ng/ml, 101 ng/ml, 102 ng/ml, 103 ng/ml, 104 ng/ml) showed that the cut-off point ≥ 98 ng/ml had a sensitivity 93.1%, specificity 100%, positive predictive value 95.34% and a negative predictive value of 100%. Initial cut-off point of sVCAM-1 ≥ 100 ng/ml and ≥ 101 ng/ml have the same value in terms of sensitivity

100%, specificity 100%, positive predictive value 100% and negative predictive value 100%. At the cut-off point ≥ 102 ng/ml mempunyai 97.56% sensitivity, 100% specificity, positive predictive value of 100% and a negative predictive value of 96.67%. At the cut-off point ≥ 103 ng/ml and ≥ 104 ng/ml had sensitivity 95.12%, specificity 100%, positive predictive value 100% and negative predictive value 93.55%. All of these points are distance from the diagonal line and significantly different, but there were only 2 cut-off point has the highest value; the points are presented on ROC curve (Figure 1).

To assess the the best cut off point levels of initial sVCAM-1 in determining the outcome can be seen on a Receiver Operator Curve (ROC) (figure 1). Sensitivity depicted on ordinate Y, while the 1-specificity depicted on the X axis. The farthest sVCAM-1 value from the diagonal line and approaching the top left corner with the largest area under the curve is the point of intersection on the boundary initial sVCAM-1 value ≥ 100 ng/ml.

Discussion

In this study, the relationship of sex with sepsis patient outcome was not significantly different with p value = 0.698, which means sex is not a prognostic factor. Similar results were reported by Hendra et al.[6], that the pediatric sepsis patients did not differ significantly between men and women with p value = 0.138. Similar results were also obtained in studies conducted by Ghuman et al.[7] who reported no differences outcomes based on sex in prepubertal patients with sepsis. Runtunuwu[8] in study conducted in Manado reported to find no significant differences between patients with sepsis and septic shock in children based on sex (P = 0.261).

Based on nutritional status, this study found no significant differences between patients with sepsis (without shock) and septic shock (p = 0.617). However, the number of patients with malnutrition status in septic shock group was higher than the well nourished patients. It is similar with a study reported by Delgado et al.[9] in

Brazil. It was found that there is no significant differences associated with nutritional status between groups of patients with sepsis related to mortality rate, however, patients with malnutrition has a higher mortality rate than well nourished patients. AStudy by Hendra et al[1] also reported there are 51.4% patients with sepsis have malnutrition status.

Similar results were obtained in studies conducted by Runtunuwu[8], which reported no difference in the output based on nutritional status in patients with sepsis and septic shock patients (p = 0.159).

Statistically, there were no significant differences on mean age between the two groups of patients with sepsis. Patients with septic shock mean age were 4.27 years, while patients without shock was 5.84 years (p = 0.497). This is similar to the study conducted by Runtunuwu[8] (P= 0.261) and Pedro et al.[10] which reported on the difference between the age group of 3-12 months, 12-36 months and >36 months in patients who died of sepsis and sepsis survival with p = 0.391, 0.104, and 0.448.

The focus of most infections in this study was respiratory tract infections, followed by infection of the central nervous system, cardiovascular and gastrointestinal. Possibly, the origin of sepsis infection is associated with the prevalence of the disease in children and national health statistics. According to RISKESDAS, pneumonia is still a major cause of morbidity and mortality in infants. Every year more than 2 millions of children in the world die from acute respiratory infections (ARI), especially pneumonia[11]. Origin of infection was reported to have an important role on the outcome of patients with sepsis. Patients who suffer sepsis from respiratory tract infections, gastrointestinal, and central nervous system have been reported to have a higher mortality rate than who suffes sepsis because of urinary tract and soft tissue infections[15]. In this study, respiratory tract infection and increasing level of VCAM-1 more frequently found in patients with septic shock (80.5%) than in patients without septic shock.

A Study conducted by Jaber et al.[13], reported an increase in levels of sVCAM-1 in sepsis patients: 199.88 ± 34.20 ng/ml (156.07-276.07) while the control group 187.45 ± 5.00 ng/ml (180.00 to 193.00) (P <0.05). Meanwhile, a study conducted by Shapiro et al.[5] found that the level of sVCAM-1 more increased in patients with septic shock than in uninfected control subjects (P <0.05). In addition, study conducted by Bavunoglu et al.[14] found significantly higher levels of VCAM-1 in septic patients compared to controled subjects. In control subjects, it was obtained VCAM-1 levels 1.25 ± 0.79 ng/ml, in patients with mild sepsis 4.04 ± 1.64 ng/ml and in patients with severe sepsis was about 3.29 ± 0.75 ng/ml. It is different from this study which found a higher level of sVCAM-1 in patients with sepsis with an average value of 83.49 ng/ml. It is due to gene polymorphism, different basic diseases and also due to local people are often exposed to infections such as skin infections, worm manifestations, respiratory infections, and other infections so, probably the levels of sVCAM-1 in the normal population in Makassar is higher than in other regions.

Based on the highest cut-off point at the 97.5 percentile of initial sVCAM-1 levels in non septic shock group which is on the value of 98 ng/ml and the lowest cut-off point 2.5 percentile of initial VCAM-1 in septic shock group. On the value 104 ng/ml, there are 7 cut-off points which can be used to differentiate between sepsis group with septic shock and without septic shock.

Initial level of sVCAM-1 ≥100 ng/mL has a positive predictive value 100% and a negative predictive value 100%. It means that if the initial levels of sVCAM-1 ≥100 ng/ml, the possibility of sepsis patients to develop septic shock is 100%, whereas when the levels of initial sVCAM-1 <100 ng/ml, the possibility of sepsis patients do not develop septic shock is 100%. In the study conducted by Bavunoglu et al.[14], the cut-off point of VCAM-1 levels in patients with sepsis based on the ROC curve was 2.34 ng/ml with 99% sensitivity, 99% specificity and AUC 1.000. There has never been study on cut point of serum levels of initial sVCAM-1 to determine the prognostic value of septic shock.

Limit of Initial level of sVCAM-1 ≥100 ng/ml showed a highly significant difference in outcomes with p = 0.000 (p <0.01). It means that the initial level of sVCAM-1 ≥100 ng/ml is a prognostic factor on the outcome of patients with sepsis.

It can be concluded that the initial serum levels of sVCAM-1 can be used as a prognostic factor in determining outcome, but noted that sVCAM-1 is not the only prognostic factor in determining the outcome; there are still other proinflammatory cytokines and other inflammatory risk factors. In bivariate analysis, it is observed there is one variable which is a prognostic factor on the outcome of patients with sepsis namely initial serum levels of sVCAM-1.

The Role of Peer Group and Enabling Factor towards the Act of Using E-Cigarettes in Adolescents

Inneke Ayuning Wulandari[1], Iken Nafikadini[1], Dewi Rokhmah[1]

[1]Departement of Health Promotion and Bihavioral Science, Public Health Faculty, University of Jember East Java Indonesia

Abstract

E-cigarette has now become a new phenomenon in Indonesian. But the pros and cons of the existence of a vapor at this time is still happening, various studies conducted to find out the actual content is a risk to health or not. Teenagers choose to use vapor with various underlying reasons. This study aims to determine the relationship between enabling factors and the role of peer gorups on the use of e-cigarettes in adolescents in Jember district. This research is an analytic study with a quantitative approach. Data was collected through accidental sampling on 76 adolescent vapor users in Jember, then the data were analyzed using chi-square test. The results of this study indicate that there is a relationship between enabling and the act of using e-cigarettes in adolescents and all the peer group roles which include social reinforcement, social modeling, social comparison and critics and agents of persuasion have a relationship with the use of e-cigarettes in adolescents. The role of government and related agencies is needed to collaborate with educational institutions to conduct research and community service on the impact of the use of vapor from the health side. The government can also collaborate with health workers to carry out promotive actions such as socialization targeting adolescents as an effort to increase knowledge because there are still many assumptions that vapor is safer for health.

Keywords: *Electric Cigarette, Youth, Enabling Factors, Peer Groups, Action.*

Introduction

Very significant industrial progress in the current era of globalization makes the business world experience rapid progress and development in all fields of business. This is also felt in the development of the cigarette industry that is with the innovation of e-cigarettes.[1] The appearance of the vapormade many conventional cigarette users began to switch to using a vapor. Vapor is a device that produces steam from the combustion of chemicals by using electric power and then flowed into the lungs.[2] Awareness about vapor has been known to the public in Indonesia in 2011 to 2013, which amounted to 10.9%. The Global Adults Tobacco Survey (GATS) in 2011 stated that of the 10.9% of people aware the existence of a vapor, 0.3% of the community had used it and continue increase.[3] The Chair Person of Personal Vapor Indonesian Association (APVI) organization, Kartasasmita, said that in 2018 the number of users vapor had reached 1.2 million and it was predicted that it would increase by 1 million in 2019.[4] On 1 July 2018 the Indonesian government imposed an excise tax of 57% as an effort to limit the circulation of vapor and control of consumption because the liquid vapor still contains tobacco. This regulation is regulated in Regulation of the Minister of Finance number 146/PMK0.10/2017.

Pros and cons about vapor still happening, various studies conducted to determine the actual content of whether a risk to health or not. Vapor was originally created as an alternative media in an effort to stop

e-mail: dewirokhmah@unej.ac.id

smoking but this function shifted to a lifestyle.[5] Vapor is used because it is considered safer, stylish and is an innovation to stop smoking. However, it is proven that e-cigarettes contain harmful substances that can interfere with health such as TSNA, DEG and carbon monoxide, long-term use can significantly increase plasma nicotine. Plasma carbon monoxide levels and the pulse rate can increase significantly, having more adverse effects than conventional cigarettes. According to research from the University of North Carolinavapor it has a worse impact on the lungs. Vapor can trigger asthma, pneumonia and chronic inflammation such as lupus and psoriasis. National Health Service also has the same opinion based on existing research, there are have a negative impact on health.[6]

Teenagers choose to use vapor with various underlying reasons. Park, et.al., explained that teenagers or young adults use vapor as an excuse to try to quit smoking (59%); reduce the habit of consuming conventional cigarettes (58%); and comfort obtained from the vaporindoors because it can be used(47%).[7] Whereas in Blue's research found the factors ofuse vapor among adolescents, namely as an effort to follow the progress of lifestyle; the steam produced can be unique-shaped; reduce effects of addiction on conventional cigarettes; and has a variety of flavors. However, in reality vapor has a negative impact on health so it cannot be said as a substitute for conventional cigarettes.[8]

Research by Aryani,et.al. stated that adolescents use vapor with references from someone they trusted.[9] The development of social life patterns in adolescents who begin to separate themselves from parents generally broadens the relationship by becoming part of members of the same age (peer group).[10] The peer group will influence its members to carry out a habit to meet their needs. Peer group has a role that is social reinforcement, social modeling, social comparison and critics and agents of persuasion.[11]

Based on the records of APVI in Indonesia there are about 3,500 shops that have many young consumers aged 20-30 years. This makes youth access to the vapor easier. The availability of supporting factors in the form of facilities,and infrastructure is a factor that allows someone to take action using the vapor.[12] This research was conducted in Jember because Jember has various tribes, customs and cultures. People who live permanently or temporarily with various diverse characteristics make access to information and behavior changes easier. This can also affect the life style of the community, one of which is about the use of e-cigarettes. Based on this the researcher wants to try to find out the relationship between the role of peer groups and enabling factors with the act of using e-cigarettesin adolescents in Jember Regency. This research uses behavior theory from Lawrence Green. The reason using Lawrence Green theory is that behavior is formed based on three factors namely predisposing factors, enabling factors, and reinforcing factors.

Materials and Method

This study uses analytical research with a quantitative approach. The study was conducted in Jember District through accidental sampling on 76 respondents. Data collected then analyzed using the chi-squaretest. Independent variables are the characteristics of respondents, enabling factors and the role of peer groups, while dependent variable is the act of using vapor. Quantitative data is obtained from respondents by distributing questionnaires.

Results

The results of research on the relationship between the enabling factors to the action using e-cigarettein 76 respondents. The participants with the enabling factors poorly action using e-cigarette by 33 respondents (43.4%). Results of analysis using test chi-square showed that the p-value obtained for 0.044 ($p<\alpha$) which means that H_0 is rejected that there is a relationship between the enabling factors to the action using e-cigarettein adolescents in Jember Regency. This can be shown in Table 1 below:

Table 1. Variable Analysis of Relationship Enabling Factors with the Action Usage E-Cigarettes

No	Enabling Factors	Action Usage E-Cigarettes						p-value
		Good		Bad		Total		
		N	%	N	%	N	%	
1.	Good	22	29	14	18,4	36	47,4	0,044
2.	Bad	33	43,4	7	9,2	40	52,6	
Total		**45**	**72,4**	**21**	**27,6**	**76**	**100**	

Results of research showed that respondents with social reinforcement poorly with action using e-cigarette good as many as 35 respondents (46.1%). The results of the analysis using chi-square test showed that the p-value obtained amounted to 0.069 ($p<\alpha$) which means that H_0 is rejected that there is a relationship between social reinforcement with action electric cigarette use in adolescents in Jember Regency. This can be shown in the following Table 2:

Table 2. Variable Analysis of the Relationship of Social Reinforcement with Actions for the Use of E-Cigarettes

No	Social Reinforcement	Action Usage E-Cigarettes						p-value
		Good		Bad		Total		
		N	%	N	%	N	%	
1.	Good	20	26,3	13	17,1	33	43,4	0,069
2.	Bad	35	46,1	8	10,5	43	56,6	
Total		**55**	**72,4**	**21**	**27,6**	**76**	**100**	

The relationship between social modeling with the act of using e-cigarettes in adolescents shows that respondents with bad social modeling have good acts of using e-cigarettes of 30 respondents (49.5%). Results of analysis using chi-square test showed that the p-value obtained for 0.039 ($p<\alpha$) which means that H_0 is rejected that there is a relationship between social modeling to measure the use of e-cigarette in adolescents in Jember Regency. This can be shown in Table 3.

Table 3. Variable Analysis of the Relationship of Social Modeling with Actions for the Use of E-Cigarettes

No	Social Modeling	Action Usage E-Cigarettes						p-value
		Good		Bad		Total		
		N	%	N	%	N	%	
1.	Good	25	32,9	4	5,3	29	38,2	0,039
2.	Bad	30	39,5	17	22,3	47	61,8	
Total		**60**	**72,4**	**21**	**27,6**	**76**	**100**	

Relationship between social comparison with the act of using e-cigarettes in adolescents shows that research respondents with bad social comparison have good acts of using e-cigarettes as many as 38 respondents (50%). Results of analysis using chi-square test showed that the p-value obtained for 0.076 ($p <\alpha$) which means that H_0 is rejected. There is a relationship between social comparison to measure the use of electric cigarette in adolescents in Jember Regency. This can be shown in Table 4 below:

Table 4. Variable Analysis of Social Comparison with Actions for the Use of E-Cigarettes

No	Social Comparison	Action Usage E-Cigarettes						p-value
		Good		Bad		Total		
		N	%	N	%	N	%	
1.	Good	17	22,4	2	2,6	19	25	0,076
2.	Bad	38	50	19	25	57	75	
Total		**55**	**72,4**	**21**	**27,6**	**76**	**100**	

The relationship between critics and agents of persuasion with the act of using e-cigarettes in adolescents, respondents with critics and agents of persuasion have bad actions of using e-cigarettes good as many as 46 respondents (60.5%). Results of analysis using chi-square test showed that the p-value obtained for 0.056 ($p<\alpha$) which means that H_0 is rejected, namely the relationship between critics and agents of persuasion to measure the use of e-cigarettes in adolescents in Jember Regency. The following Table 5 below:

Table 5. Variables Analysis Critics and Agents of Persuasion with Actions for the Use of E-Cigarettes

No	Critics and agents of persuasion	Action Usage E-Cigarettes						p-value
		Good		Bad		Total

Total		**55**	**72,3**	**21**	**27,7**	**76**	**100**	

Discussion

Action is an open behavior that can occur if the supporting factors, one of which is enabling factors, regarding facilities, and infrastructure. The relationship between enabling factors and actions of use e-cigarettes based on the analysis showed that there is a relationship between the enabling factors with the use of e-cigarettes in adolescents. The assessment conducted by Damayanti (2016) concerns the availability of facilities and infrastructure such as cost, distance, availability of transportation, and etc.[13] Hart, et.al marketing strategy and the establishment of shops vapor in strategic and easily accessible places so that most (87%) of the research respondents already knew about the existence of vapor. The influence of adolescence is more likely by a variety of strategies and approaches. In addition to their online store, also offline stores.[14]

In addition actions can be realized if supported by people around. Peer groups have a greater influence because teenagers are often in the environment outside the home, the peers have a greater influence in forming attitudes, talks, interests, appearance and behavior. Teenagers need a few time in the process of self discovery by trying all the things that make them comfortable both in terms of social and sexual orientation, especially at the aged of 18 old.[15]This is consistent with the research of Ariyani, et.al in 2018 mentions that teens use vapor with references from someone they trust (personal references) that makes them decide to use friends.[9]Peer groups have four roles namely social reinforcement, social modeling, social comparison and critics and agents of persuasion.

Relationship between social reinforcement with the act of using e-cigarettes,have a bad social reinforcement with an act of using e-cigarettes good. Lorean (2017) research which shows that having friends who have used vapor will be more likely to try using vapor.[16] Teenagers will strengthen, maintain, and eliminate social behavior based on a pleasant reaction or not given by their friendship groups.[11] Other research by Johnston, et.al., states that from an epidemiological perspective, adolescents often feel attracted by new products and based on history as the line front of change in society in

the use of substances that are manifested in the general public.[17]

The relationship between social modeling with the use of e-cigarettes, have bad social modeling with a good use of e-cigarettes. Atmojo (2017) produced that all research subjects had friends who used vapor, roommates, friends hanging out, or campus friends. This shows that the subject of his research used vapor because his friends also used vapor .[18]

Relationship of social comparison with the act of using e-cigarettes in adolescents. According to Shaffer in Nugrahawati (2011) teenagers often draw conclusions from within themselves by comparing the behavior displayed by their peers.[11] According to Stephenson, et.al., in Sutfin, et.al., (2013) looking for sensation is a personal trait owned by someone who then produces stimulation, new experiences and making a decision to use vapor.[19]

The relationship between critics and agents of persuasion with the act of using e-cigarettes. In this study shows that it has poor results with the action of using e-cigarettes with good results. Adolescents peer groups have an important position for adolescents so they tend to follow criticism, persuasion or acts of encouragement given by their friendship groups. Another study conducted by Istiqomah et.al. (2016), said that most of the research respondents, namely individuals who used vapor, received support from the reference group, where some respondents had received at least one vapor freefrom their friends as a start using vapor, and received more than five times refillfluid vapor.[5]

Supervision of the distribution of e-cigarettes in Indonesia is still not regulated in Indonesian law. In Government Regulation No.109/2012 specifically article 59, only regulates the supervision of addictive substances from processed tobacco products.[20] Based on information from employees at shop, some underage teens wanted to try buy vapor. They hire the services of others who are old enough to buy because in some shoponly serve a minimum age of 18 years. Users of e-cigarettes not only have a male gender but also a female. Respondents in this study found thatusers vapor not only male but there were also female. This is in line with research conducted by Arifin (2018)because women assume that they also have ability to use vapor. But many of them do not think about the effects caused by the use of vapor.[1]

Conclusions and Recommendations

The results of this study indicate that there is a relationship between the enabling factors based on availability to the action e-cigarette in adolescents in the Jember. All of role of a peer groups that includes social reinforcement,social modeling, social comparison, and critics and agents of persuasion have a relationship with the act of using e-cigarettes in adolescents. The role of government and related agencies is needed to collaborate with educational institutions to conduct research and community service on the impact of the use of vapor from the health side. The government can also collaborate with health workers to carry outpromotive actions such as socialization targeting adolescents as an effort to increase knowledge because there are still many assumptions that vapor is safer for health.

Declaration of Conflicting Interests: The authors declared no potential conflict of interest with respect to the research, authorship, and/or publication of this article.

Funding: The authors received no financial support for this scarch, authorship, and/or publication of this article.

Acknowledgments: The researcher would like to thank the Research Institute and Community Services (LP2M) University of Jember, Faculty of Public Health University of Jember, as well as to all respondents of this study who have taken the time to be fully involved during the research.

Abstract

One form of health promotion for school students is the school health program in every region in Indonesia. The purpose of School Health according to the Ministry of Education and Culture in 2012 is to improve the quality of education and student achievement by improving the quality of clean and healthy life and health status of students and creating a healthy environment. This research was conducted using qualitative descriptive method with the aim of developing a model of implementing school health programs. Respondents in this study were students from junior high schools managed by the government and junior high schools managed by private parties implementing school health programs. The results of this study are expected to support existing models by improving school health management through a systems approach so that students can improve their performance through improving clean and healthy living behaviors and a healthy environment.

Keywords: *Health promotion, health school, development, junior high schools, systems approach.*

Introduction

School-age children are faced with very complex and diverse health problems. Various kinds of health problems arise in elementary school-age children, but problems that are commonly associated with healthy living behavior (Nugraheni, 2019)[(1)]. While for middle school and high school age children, the problem is related to risky behaviors such as drug abuse (Narcotics, Psychotropic and other addictive substances), unwanted pregnancies, unsafe abortion, sexually transmitted diseases (STDs), including HIV/AIDS adolescent reproductive health accidents and other trauma (MOH, 2004)[(2)].

Efforts to foster school-age children can be done through the School Health program in every region in Indonesia. The School Health is one vehicle for improving student health status (Nugraheni, 2019)[(1)]. The target is students and other school communities with the aim of improving students healthy life skills. School health services that involve all relevant parties such as students, families and community service providers, school nurses and school doctors play a more complex role to prevent, facilitate and handle health problems to improve the education of all students (Kolbe, 2019) [(3)]. So students can learn, grow and develop optimally and become quality human resources. According to Suliha (2002) the aim of School Health is to improve the ability of healthy living and the health status of students as early as possible and create a healthy school environment so as to enable harmonious and optimal growth and development of children in the context of quality Indonesian human formation[(4)].

Based on the Principles for the Development School Health that have been determined by the government, School Health has three main programs known as

"TRIAS UKS". The three programs include health education, health services and fostering a healthy school environment. School Health activities must be carried out at all levels of education, from the level of kindergarten, elementary school, Junior High School (JHS) to Senior High School (SHS) and vocational education, both under the guidance of the Ministry of National Education and the Ministry of Religion, including Islamic boarding schools and out-of-school education channels (MOH, 2004)[2].

The fundamental problems that occur in the development and development of School Health include: Clean and Healthy Life Behavior has not reached the expected level, the existence of health problems in school-age children, limited human resources available facilities and infrastructure, lack of optimal coordination between agencies, lack of the optimal role of the School Health Advisory Team as well as the limited rules and regulations governing the management of School Health (Ministry of Education and Culture, 2012)[5].

The implementation's problem of School Health in Banyuwangi is not much different from the problems raised by the Ministry of Education and Culture. Strong effort and solid cross-sectoral cooperation are needed to implement the School Health program in accordance with established legislation so that the benefits of implementing the School Health program such as the realization of healthy schools and the creation of the next generation that are physically, mentally and spiritually healthy for a prosperous life.

Based on these conditions, it is necessary to take concrete steps to optimize the implementation of the School Health program, especially in service activities. So the need for innovation in the development model of the School Health program in an effort to improve the health of JHS students in Banyuwangi. The development innovation was carried out by optimizing all elements in the School Health program service and integrated with teaching and learning activities in schools. So as to be able to create personal students who have the ability and awareness of the importance of health.

Material and Method

This research use descriptive qualitative approach. This approach is used with the aim of delving deeply into the knowledge, opinions, opinions and views on the current implementation of the School Health program and exploring more information about the partnerships that have been built in optimizing the implementation of the School Health program. Data collection was carried out in four JHS in Banyuwangi which consisted of two public JHSs and two private JHSs for three months, starting April - June 2016. This study used in-depth interviews and FGD method conducted through several stages, namely situation analysis and primary data collection.

The variables of this study consisted of the characteristics of the informants, the knowledge of the informants, opinions and views of informants about the implementation of School Health, management of School Health implementation, obstacles experienced, strengths possessed, future expectations regarding the implementation and utilization of School Health specifically implementing "TRIAS UKS".

Findings: There are three main activities of the School Health activity that are commonly known as the "TRIAS UKS". School Health is a form of health promotion and education efforts in the school environment. In modern school health programs include 10 interactive components such as health education, physical education and physical activity, environmental and nutritional services, health services, counseling, psychological and social services, physical environment, social and emotional climate, family involvement, community involvement and health employee (Kolbe, 2019)[3]. For this reason, the implementation of School Health is based on the awareness of increasing the welfare of the school community in particular. In terms of this, School Health has an important role in health development in schools to prepare a healthy, smart and prosperous generation.

A. Implementation of the School Health Middle School Program in Banyuwangi Regency: To achieve School Health goals, promotive, preventive, curative and rehabilitative efforts are carried out as early as possible in accordance with the "TRIAS UKS", such as:

1. **Health Education in School:** Health education is a dynamic process of behavior change, where the change is not just the process of transferring material or theory from one person to another and not a set of procedures, but these changes occur because of the awareness of the individual, group, or society itself (Wahid IM & Nurul C, 2009: 9-10)[6]. The health education program must also emphasize behavioral change skills,

such as goal setting and self motivation, to positively impact students' physical activity behavior (Dai, 2019)[7]. The results of the study show that in most of the JHS in Banyuwangi have implemented School Health programs in the field of health education such as:

a. Increase knowledge, behavior attitudes and skills for a clean and healthy life.

b. Planting and habituating clean and healthy life and deterrence of bad influences from outside.

c. Cultivating a healthy lifestyle so that it can be implemented in everyday life.

In addition, health education can be carried out through intracurric and extracurricular activities. The intracurric activity is a part of the school curriculum such as health science subjects, physical education and health subjects or subjects that can be inserted in health sciences. While extracurricular activities are health education that can be included in activities outside of school hours in order to instill student's healthy behavior.

2. **School Health Services:** School Health service activities are minimum standard service activities in schools. Health services can help health education for students (Giri, 2018) [8]. Not only the provision of material and information to students regarding their health, but also practice through relationships with health workers. School health also services include regular health examinations, open-door clinic acute medical care for minor symptoms or injuries, some specialist care as well as the promotion of wellbeing and safety at school (Kivimaki, 2018)[9]. The results of interviews with School Health services can be seen that the information stated that there were services provided by School Health in schools. The implementation of School Health services in Banyuwangi includes:

a. Early Growth and Stimulation Detection and Intervention

b. Health screening and periodic health checks

c. Dental and oral examination and treatment.

d. Development of Clean and Healthy Life Behavior

e. First Aid In Accident/First Aid In Disease

f. Provision of immunization

g. Physical Fitness Test

h. Eradication of Mosquito Nest

i. Adding blood table ts

j. Giving worm medicine

k. Use of the school yard as a family medicine park/live pharmacy.

l. Health education and counseling

m. Guidance and supervision of healthy canteens

n. Nutritional information

o. Post-illness recovery

p. Health referrals for public health center/ hospitals.

3. **Development of a Healthy Environmental Life:** The development of the school environment aims to create a healthy environment in the school that allows every citizen of the school to achieve the highest degree of health in order to support the achievement of a maximum learning process for each student (Ministry of Education and Culture, 2012)[5]. Fostering a healthy school environment includes:

a. Implementation of cleanliness, beauty, comfort, order, security, longing and kinship.

b. Development and maintenance of environmental health including smoke free, pornography, psychotropic narcotics and other addictive substances and violence.

c. Fostering cooperation between school communities.

Based on the explanation above, the "TRIAS UKS" activities have run quite well although not yet as a whole. The School Health implementation team is still focused on the "TRIAS UKS" activities and the fulfillment of School Health facilities and infrastructure, in addition to the rather heavy extracurricular activities in JHS.

B. Model of School Health Program Development in Middle School: The program is a collection of real, systematic and integrated activities, carried

out by one government agency or more or in the framework of cooperation with the community or which is the active participation of the community in order to achieve the goals and objectives that have been set (Pramono, 2011: 45)[10].

One example is the substance of special service management engaged in health at the school scope, namely School Health Unit. This school service management is basically made to facilitate learning and can meet the special needs of students at school. The implementation of School Health activities still refers to the "TRIAS UKS". There has been no development of the middle school health program. The following is the identification of the expectations of the School Health Implementation Team:

1. Obtain School Health guidelines
2. Medication assistance
3. The presence of medical personnel at the School Health
4. Repair of rooms and School Health facilities
5. Training a small doctor
6. Implementation of the School Health Competition as a form of existence and mutual motivation
7. Education about the dangers of free sex, HIV and drugs.
8. The activity of forming the character of independence
9. Involvement of educational institutions
