Based on the identification of the above expectations, it can be concluded that the development of School Health at the Implementing Level is strengthening the input components and enriching activities in the process components. While the implementation of School Health activities at the District and District Guidance Team Levels is still focused on organizing and coordinating the Team Builder mechanism. So, the function of fostering and developing School Health has not been implemented optimally.

WHO in Notoatmodjo (2012) launched five (5) health promotion strategies in schools, namely advocacy, cooperation, capacity building, research and partnerships [11]. Thus, the model of developing the JHS School Health in accordance with the conditions of the JHS in Banyuwangi is strengthening the management of School Health with a systems approach. The following is a scheme for strengthening the management of JHS School Health in Banyuwangi Regency.

Caption:

1. **Input:** In the implementation of the School Health program in Banyuwangi Regency, the staff who organized this program were the School Health Implementation Team (headmaster, supervisor of School Health, teacher council, Student Council, School Health administrators), the savings team of the School Health level and the district level supervisors team. For facilities that support the implementation of this program such as the School Health room administration desk, mattress, pillow, bolster, blanket, registration book, cupboard, medicines and so on. The implementing of the School Health program is using manual method. All of these input factors must work together in order to realize behavior change to achieve optimal health status.
2. **Process:** The management function is starting from planning, organizing actuating and controlling.
   a. **Planning:** Planning is the initial stage in the management process. Planning according to Koontz and O'Donnell (1964) is "*involving selecting the objectives and policies, programs and procedures for achieving them-either for the entire enterprise or for any organized part*"[12]. Planning includes decision-making activities because it includes the selection of decision alternatives.

   Implementation of the School Health program planning in Banyuwangi, planning was carried out by the School School Health Implementation Team but was not integrated with the District and District Head of the School Health Development Team because the organizing of the School Health Development Team in Banyuwangi didn't work. This can occur because there is no planning for public health center specifically for School Health at the District Level.

   While the planning of School Health guidance at the District Level is integrated with the Health Office and the majority is joined by the public health center's program. So that the planning of the JHS School Health program in Banyuwangi is only limited to planning by the School Health

Implementation Team itself.

b. Organizing: Organizing can be formulated as an overall management activity in grouping people and assigning tasks, functions authorities and responsibilities of each with the aim of creating useful and effective activities in achieving predetermined goals (Manullang, 2008)[13]. According to Terry (2006) Organizing includes[14]:

1. Divide the components of activities needed to achieve goals into groups
2. Dividing tasks to someone manager to hold the grouping
3. Establish authority between groups or organizational units

The School Health executive team that came from students namely 7th, 8th and 9th grade students fulfilled the requirements after the School Health training. In line with the organization of the School Health program implementation team in schools, it was not balanced with the organization of District and District advisory teams. Because the sub-district advisory did not know about the team implementing this development. Thus, it resulted in the non-implementation of the task of School Health Guidance Teams in conducting the development of School Health in Banyuwangi.

c. Actuating: Activation and Implementation (actuation) is an action to make all group members want to try to achieve organizational goals in accordance with planning (Prayitno, 1997)[15]. In management, other terms will often be encountered for mobilization and implementation functions, namely motivating, directing, influencing, commanding.

The implementation of School Health must be in accordance with the health needs of students. Implementation of these activities can be in the form of "TRIAS UKS". These needs can cover physical, psychological, social and spiritual needs. The implementation of health business activities can be carried out well if all the residents of the school, supporting facilities and infrastructures and various cross-sectoral agencies can contribute to the success of this activity.

d. Controlling: Planning is closely related to the function of supervision or control because it can be said that the plan is a standard or tool of supervision for the work being done. George R Terry (2006) suggested "*control is to determine what is accomplished, evaluate it and apply corrective measures, if need, to insure result in keeping with the plan*". Furthermore, Newman said "*control is the performance that conforms to plan*"[14].

Control of purpose of school health activities includes monitoring and evaluation efforts supported by recording and reporting. Control must be carried out periodically and continuously, one of the method used by the Government (Regional) in monitoring and evaluating the implementation of health activities in schools. The main objective of control is to make what is planned become a reality (Manullang, 2008)[13].

The supervision of the School Health program in Banyuwangi is carried out by the implementation team and the subdistrict and district development team. At the supervisory level, the evaluation is carried out in each semester. However,0020supervision of the sub-district and district supervisors team did not work due to barriers to integration with monitoring programs in the puskesmas.

3. **Output:** The output factor of the implementation of this school health business is the change in behavior from unhealthy habits to clean and healthy living habits and a healthy environment.
4. **Outcome:** The outcome factor of the implementation of this school health effort is the increasing quality and achievement of students both academically and non-academically according to the purpose of education at school.
5. **Impact:** The impact of the results of the implementation of health business is expected to increase the level of health of students so that the growth of students continues to increase and free from sources of disease.

Conclusion

Based on the results and finding of research on the development of the School Health program in JHS in Banyuwangi it can be concluded that the planning of the School Health program is still routine which results in less optimal organization. However, the implementation of the School Health program is in accordance with the "TRIAS UKS" and its supervision is already good at the

level of the implementation team. It's just that the School Health program development has not been implemented optimally.

Therefore it is necessary to make efforts to optimize the implementation of the School Health program in accordance with the Policy Principles for the Development and Development of School Health and the School Health Development Team. With the model of developing a JHS School Health program in Kabupaten Banyuwangi, "*Strengthening School Health Management with a System Approach*" is expected to be able to optimize the implementation of the School Health program.

Personal and Behavioural Determinants of HIV Transmission among Transgender Women in Indonesia

Maria Silvia Merry[1], Sukma Putra[2]

[1]Medicine Faculty, Duta Wacana Christian University, Jl. Doktor Wahidin Sudiro Husodo, [2]International Business Management Program, Management Department, BINUS Business School Undergraduate Program, Bina Nusantara University, Jakarta, Indonesia

Abstract

Purpose: This study aimed to understand determinants of HIV transmission among transgender women also known as *Waria* in Yogyakarta, Indonesia.

Method: One-to-one in-depth interviews with twenty-nine *Waria* living with HIV was conducted. They were recruited using purposive and snowball sampling techniques.

Results: The results indicated that personal factors including the lack of knowledge about HIV and condoms played a supporting role in the transmission of HIV among the participants. Early sexual, being interested in sex partners, engagement in transactional sex and the needfor sexual satisfaction were identified as supporting behavioural factors for HIV transmission.

Conclusions: The study findings indicate the need for HIV/AIDS interventions that address the economic aspect of *Waria* in Yogyakarta and other similar settings. Furthermore, educational programs that would raise awareness of HIV in schools and the need to formulate policies and bylaws that protect children from having sex with adults including their teachers should be instituted in Indonesia.

Keywords: *HIV infection, personal and behavioural factors, transgender women, Waria, Indonesia.*

Introduction

The prevalence of HIV infection among transgender women populations has been documented in copious studies and reports worldwide.[1-3]Available evidence often derived from local studies conducted in Asia and the Pacific region indicates that Indonesia, India, Nepal, Pakistan and Myanmar to be the top five countries with the highest prevalence of HIV infection in transgender women populations.[2] In the Indonesian context, transgender women are also known as *Waria*.[4]

A range of HIV risk factors such as needle sharing, injecting drugsand injection of female hormones have been reported in these populations.[5,6] Other factors supportive of HIV transmission among these populations include having a history of sexually transmitted infection[7], unprotected anal intercourse (UAI) with multiple sex partners[1,6,8] and engagement in commercial sex work.[6,9,10] The lack of knowledge or inadequate information on the ways HIV is transmitted and could be prevented have also been reported to be supportive of risky sexual behaviours for HIV transmission among these populations[10-12].

Despite the reported high HIV prevalence, there is paucity of evidence on factors supportive of HIV transmission among transgender women in the context of Yogyakarta and in Indonesia in general. The diversity of factors and the mechanisms through which HIV transmission is facilitated among these populations in Indonesia have not been explored[13]. The current study aimed to understand factors associated with HIV transmission among transgender women population in Yogyakarta, Indonesia.

Method

Study design, Recruitment of participants and data collection: A qualitative inquiry was conducted in Yogyakarta, Indonesia from December 2017 to February 2018. The qualitative study design enabled the researchers to have direct interactions with and observe the settings and situations of the study participants[14]. Purposive sampling which was followed by snowball sampling technique were used to recruit the study participants (n=29). Participants were eligible for inclusion based on two criteria: (i) HIV positive *Waria* and (ii) 18^{+} years old[15]. Open ended one-to-one in-depth interviews were carried out by the first (female) and the second (male) authors who are experienced qualitive method researcher, have public health educational background. Each interview was conducted at mutually agreed places and times by both the participants researchers. The interview with each participant took approximately 45 to 90 minutes. Although participants were offered a chance to review their individual transcripts none of them took this offer.

Data Analysis: Data analysis was guided by the thematic framework analysis by Braun and Clarke.[16] The framework analysis involves six steps of qualitative data analysis including data familiarisation, generation of initial codes, the search for themes, the review of themes, defining and naming themes and the production of the report.[15]

Results

Personal Factors: Knowledge of HIV/AIDS and condoms seemed to have been well disseminated among the study participants prior to this study. All the participants had the basic knowledge of HIV transmission and prevention. However, it was obvious from the participants' responses that most of them learnt about HIV/AIDS and condoms after they were diagnosed with HIV infection. They had engaged in UAI for years before HIV diagnosis, which seemed to be one of the significant factors leading to HIV transmission among them:

"I didn't know anything about HIV and condoms prior to the diagnosis. After I was diagnosed with HIV, I received information related to HIV/AIDS, HIV/AIDS-related health services and about condoms. Condom provision here is free of charge …." (P4).

"I did not have information at all about this virus before moving here [Yogyakarta]. I did not know about condoms. Never thought of HIV or condoms before I was diagnosed with HIV. Here, information about HIV or condoms is easy to access…." (P16).

Behavioural factors:

Early sexual debut: Early sexual debut was a common practice among the study participants, which seemed to predispose them to HIV infection. It was indicated that all the participants had engaged in sexual encounters at early age with their friends or school teachers. Coupled with the lack of awareness about the protective effect of condoms for safe sex, such a practice placed them at increased risk of contracting HIV infection:

"If I am not mistaken, I had sex [UAI] for the first time when I was 13 years old. …. Never used condoms back to those days, I was still very young and did not know anything about condoms" (P2).

Participants' personal interests in sex partners, curiosity to experience sexual intercourse sensations and engagement in transactional sex were found to be the supporting factors for early sexual debut. An early engagement in UAI seemed to be a result of the feelings participants had towards their sexual partners and the curiosity to experience sexual sensations. Additionally an early debut in commercial sex work to earn was one of the highlights emerging from the interviews, which may have facilitated their HIV acquisition:

"I fell in love with my senior high school teacher and often went to his place. We were close, so once he asked me to have sex, I could not refuse…." (P17)

When asked whether they would be able to indicate how and when they were infected with HIV, participants seemed unsure of whether their exposure was during an early stage of their engagement in UAI and transactional sex work or after they had been long involved in these practices:

"I may have gotten it [HIV infection] at the early stage of my engagement in sex with partners or clients because none of them used condoms. I did not know about condoms either…. I never used injecting drugs and received blood donor from other people" (P21).

Multiple sex clients per night and sex without condoms: Regular engagement in UAI with multiple sex clients seemed to have playedan important role in the HIV transmission among transgender populations. The interviews revealed that the participants had a sustained engagement in sex work and had multiple sex clients every night, which were strong vulnerability factors supportive of HIV transmission among them:

"…. I used to have more than ten [sex] clients every night. It was tiring but I liked it, so I just enjoyed. Now, sometimes five [sex clients], sometimes less than five …." (P5)

Having multiple sex clients meant that the current study participants had to tolerate to a range of sexual practices set by different clients, including whether or not condoms were used. For example, participants revealed to have been inconsistently using condoms due to clients' demand oftransactional sex without condoms:

"Condom use is dependent upon the clients, if I ask my client to use but he does not want to use then I can't do anything. If I refuse to serve him then I don't get money to survive" (P2).

Inconsistent condom use as acknowledged by all participants, was still a common practice among the study participant even though they have been tested positive for HIV:

"I used condom inconsistently until now. Now it is not because of the lack of condoms as it was but the preference of clients. Clients pay me, so I should indulge their preference to not use condom. This may transmit HIV to them …." (P26).

Engagement in UAI or sex without condoms with multiple sex clients was revealed to be the main route of HIV transmission among the study participants. This was reflected in the following comments provided by the participants during the interviews:

"I am sure some of my clients transmitted the virus to me because I meet [have sex with] clients almost every night and most of them do not prefer to use condoms" (P27).

Hidden HIV status from sex clients: Some participants realised that the concealment of HIV status from sex clients could be a factor for the spread of HIV infection among transgender populations. Some participants appeared to understand that they could transmit the virus to their clients and their clients could also transmit it further to other transgender women as they all drew from the same pool of clients in this study settings:

"I know it is highly likely that I may have spread the virus to some of my clients as well because they often want to do it [have sex] without condoms, but what can I do? I cannot tell them that I have the virus….." (P10).

Among the major reasons for not disclosing their HIV status was the fear of losing clients and income as if found out about the status as a result of disclosure:

"I don't tell any of my clients about my status because I am afraid if they know then no one would want to book me and they [clients] can find and book the others [transgenders]" (P29).

Avoiding discussion on HIV/AIDS topic was revealed to be a strategy used by the participants to conceal the HIV status from their clients:

"I try to avoid any talk related to HIV/AIDS or other sexually transmitted infections because I don't want my clients ask me about my HIV status" (P26).

Sexual need or satisfaction: The engagement of transgender women in transactional sex seemed to extend beyond the obvious economic reasons. Personal sexual need or satisfaction was found to be additional driving factor for transgender women's engagement in transactional sex:

"I like doing this [selling sex] because I get money and sexual satisfaction as well. As a transgender person, dressing up and looking beautiful and getting booked by clients make me feel happy" (P18).

Discussion

At the time of data collection, it appeared that the study participants were better informed about HIV infection and protective effects of condoms than before their diagnosis. Prior to HIV testing, participants lacked knowledge about HIV transmission and prevention. The lack of knowledge and consistent engagement in UAI over the years facilitated the transmission of

HIV infection among them. The study findings are in line with Bandura's concepts in the social cognitive theory (SCT)[17] and previous findings[10,18], which show the influence of perceptions or knowledge (e.g., participants' lack of knowledge about HIV transmission and prevention or condoms) on the sexual behaviours such as engagement in UAI, which made them at risk for acquiring HIV infection.

It was also indicative that in this study behavioural factors were the main contributors for HIV transmission among interviewed *Waria*. It is reasonable to theorise that coupled with the lack of awareness about the existence of HIV, their engagement in UAI practices at early age involving other significant people, such as teachers (adults) could have placed them at a high-risk for HIV transmission. Their engagement in UAI practices at early age was purely driven by their feelings to sex partners, curiosity to experience sexual intercourse sensation and engagement in commercial sex work. These findings support the construct of the SCT and previous findings[6,17,19] indicating the influence that personal factors (e.g., in this study: participants' feelings towards their sex partners and curiosity towards sexual sensation) have on sexual behaviour or engagement in sex including UAI. Additionally, the findings also report consistent and regular engagement of the participants in UAI practice with multiple sex clients as a further high-risk behavioural factor supportive of HIV transmission among *Waria*. This finding supports previous findings[6,9,19] reporting the engagement of transgender women in commercial sex work as the supporting factor for sex without condoms a precursor for HIV transmission and re-infection.

In conformity to prior findings about *Waria* hiding HIV status from their primary and other sexual partners for fear of physical and sexual abuse and the inability to negotiate condom use[6,20], the findings of the current study also reveal that participants hid their HIV status and tried to avoid HIV/AIDS-related conversations with their sex clients, even when they were engaged in UAI. However, the main reason why the current participants failed to disclose about their HIV status and negotiate condom use seemed to be the fear of losing their clients and subsequently, the loss of income. On the other hand, clients who enlisted the service of these *Waria*may have lacked awareness of potential of being infected with HIV infection from the transgenders, which is a serious problem that may need to be addressed to protect both the *Waria* and their clients. These findings support the SCT concept[17] about the influence of personal factors or what people believe or think (e.g., losing sex clients and income) on their behaviour (e.g., engagement in UAI, not negotiating condom use and hiding HIV status). Hiding HIV status and UAI practices between the transgender women and their sex clients seemed to not only support HIV transmission among the study participants but can also bridge the HIV transmission to the general population through their clients who could have other sex partners from the general population.

Conclusions

The present study reports several factors associated with the HIV transmission among the transgender participants. Behavioural factors including early sexual debut, hiding HIV status and having UAI with multiple sex partners were reported to support the HIV transmission among the study participants. Sexual gratification was additional factor that led the study participants to engage in the above high-risk sexual behaviours. Moreover, the study findings indicate the high possibility of HIV transmission and re-infections, not only within *Waria* and their sexual clients, but to the general population due to the fact that *Waria* draw their clients from the same pool of clients who are also members of the general community (who may have sexual engagement with non-*Waria* populations). Educational programs that would raise awareness of HIV in schools and the need to formulate policies and bylaws that protect children from having sex with adults including their teachers should be instituted in Indonesia.

Effect of Epilepsy and Antiepileptic Drugs on Lipid Profile of Epileptic Children

Marwa Waly El-Din Ali[1], Gamal Taha Soliman[1], Enas Mahmoud Hassan[2], Laila El-Morsi Aboulfotoh[1], Rasha Nady Saleh[2]

[1]Department of Pediatric, [2]Department of Neurology, Faculty of Medicine, Minia university Egypt

Abstract

Background: Epilepsy is one of the most common neurological disorders, which required long term therapy or lifelong treatment in some cases. Chronic use of antiepileptic drugs (AEDs) therapy might modify some vascular risk factors, Since atherosclerotic vascular alterations may start early in life, this study focuses on dyslipidemia which is a major atherogenic risk factor among epileptic children.

The aim of this study: Was to evaluate the effect of epilepsy and antiepileptic drugs (AEDs) on lipid profile of children with idiopathic epilepsy.

Method: This study was carried out on 80 children, their age rage (7-16) divided into 20 epileptic children treated with new AED therapy,20 epileptic children treated with old AED therapy (VAP & CBZ namely),20 epileptic children newly diagnosed epileptic (according to ILAE2014 diagnostic criteria of epilepsy) they didn't receive medication till the time of study and 20 healthy children their age and sex matched served as a control . Measurement received for all participant include detailed history, clinical examination,neurological examination and serumfasting lipid profile, while the analysis of seizure (onset, type, frequency and classification of epilepsy according to (ILAE2017)), inter-ictal EEG, history of AEDs administration; daily dose and compliance to medication)were for epileptic patient only.

Result: Serum TC, LDL were significantly higher in epileptic children treated with (old and new generation) AEDs than other groups, TG and VLDL were higher in epileptic children treated with old AEDs than other groups, while newly diagnosed epileptic children have higher LDL than control group, on the other hand there is a significant higher HDL in epileptic children treated with new antiepileptic drugs than newly diagnosed epileptic children and epileptic children treated with old antiepileptic drugs.

Conclusion: Epilepsy and antiepileptic drugs especially old generation antiepileptic drugs are considered risk factors of dyslipidemias & atherosclerosis. We recommend routine monitoring of the serum lipid profile in epileptic children especially they treated with old generation AEDs (VAP and CBZ namely).

Keyword: *Epilepsy antiepileptic drugs AEDs serum lipid profile old AEDs new AEDs.*

Introduction

Epilepsy is one of the most prevalent chronic neurologic disorders[(1)]. Many people with epilepsy receive lifelong prescription treatment.

Older antiepileptic drugs (AEDs), mainly enzyme inducers (EIAEDs), may be associated with more adverse effects than newer AEDs. For example, they alter lipid profile, increasing serum cholesterol levels [(2)]. However, there is a lack of information about the prevalence of dyslipidemia related to the use of AEDs, which would facilitate appropriate management to reduce the risk of

Corresponding Author:

Department of Pediatric, Faculty of Medicine, Minia university Egypt
e-mail: drmarwawalydeen@gmail.com
Contact No.: 01026521115

vascular diseases. Another AED that has been related to vascular risk factors is valproic acid (VPA), which has been associated with metabolic syndrome[3]. For these reasons, some authors have suggested starting new AEDs in newly diagnosed patients or changing EIAEDs if patients experience metabolism-related effects[4]

However, limited data are available especially in children to determine the effects of AED son lipid profile as a vascular risk factor for atherosclerosis .

Materials and Method

- This study was a hospital based cross-sectional study was conducted in Minia university hospital, this study carried out on 80 children above the age of 7 years with age range (7-16), selected subjects divided into 4 groups: the group I included control (n=20), Group II included newly diagnosed epileptic children before starting treatment with AEDs (n=20), group III included epileptic children receive old generation AEDs and lastly group IV included epileptic children receive new AEDs, the epileptic children receive AEDs in group III & IV they receive mono-therapy antiepileptic drugs (old and new)for period not less than 2 months) .
- All participants were evaluated forall measurement including demographic and clinical data and serum lipid profile complete clinical examination and anthropometric measures: weight, height and BMI and complete neurological examination except the analysis of seizure and EEG for diseased patients only.

Measurement for epileptic patient:

- Analysis of seizures includes duration of epilepsy careful history taking from patients or near relative to determine, type of epilepsy according to (ILAE2017) and history of Antiepileptic drugs administration: as regards type, dose and compliance.
- Digitalelectro-encephalogram for all patients in the study:

All patients were submitted to Nihon Koden digital EEG, the EEG was carried out on 16 channels. (the patient hair was washed with water and soaps), crocodile electrodes were applied according to 10-20 mv international system of electrodes placement recording was made using 50mv, calibration, with eye of the patient closed, provocation with hyperventilation and photic stimulation was performed in every record. EEG was reported by double blind separation technique by 2 professional neurophysiologists and discussed with colleagues in the department of clinical neurophysiologyto estimate EEG finding in diseased patient .

Specimen Collection: Sample was collected from study all participants, 5ml of venous blood was collected by trained lab technician under sterile conditions using a disposable syringe between 9.00 to 10.00 a.m. after fasting at least (8-10h) and the sample was tested for TC, HDL-C, LDL-C and TG. The blood was allowed to clot at room temperature and centrifuged at 3000rpm for 10min to separate serum. It was then kept frozen at -20°C to be analyzed later on.

TC was calculated by enzymatic method and expressed in mg/dl. HDL-C was calculated using polyanion precipitation and expressed as mg/dl. LDL-C was calculated using Friedewald's equation and expressed in mg/dl. Triacylglycerol in serum was converted to glycerol and then estimated using glycerol kinase enzyme based kinetic method and expressed in mg/dl.

Ethical Permission: Ethical permission to conduct the hospital based study was obtained as written & verbal consent from all participants.

Exclusion criteria:

1. Patients with secondary epilepsy,
2. Patients with other neurological or psychiatric disorder,
3. Patients with other genetic or medical disorder,
4. Patients with serious illness, malignancy or other complications,
5. Patients on more than one antiepileptic drug.

Statistical Analysis:

- Data obtained from patients with epilepsy and control cases were fed into computer soft were package (SPSSS, version 20) through which, descriptive statistics were calculated descriptive statistics, i.e. .mean ± Standard deviation (SD), Range, median and inter quartile range (IQR).
- One-way ANOVA test for parametric quantitative data between the four groups followed by post Hoc Tukey's analysis between each two groups, Kruskal Wallis test for non-parametric quantitative data

between the four groups followed by Mann Whitney test between each two groups

- Chi square test (if expected values within cell > 5) and Fisher's exact test (if expected value within cell < 5) for qualitative data between the groups

Superscripts with same small letter indicate insignificant difference between each two groups, otherwise there was significant difference between each two groups

*: Significant level at P value < 0.05

Results

The results of this study were summarized and illustrated in the following tables and figures

Table (1): Demographic of all studied groups

		Group I	Group II	Group III	Group IV	P value
		N=20	N=20	N=20	N=20	
Age	Range Mean ± SD	(7-16) [a] 9.9±2.8	(7-16) [a] 10.9±2.1	(8-14) [a] 9.2±1.8	(7-14) [a] 10.8±2.5	0.079
Sex	Male Female	9(45%) [a] 11(55%)	10(50%) [a] 10(50%)	14(70%) [a] 6(30%)	12(60%) [a] 8(40%)	0.392
BMI	Range Mean ± SD	(10.2-21.8) [a] 17.1±3	(15.4-21.5) [a, d] 18.3±1.7	(14.5-24) [b, d] 19.6±3.2	(15.4-21.6) [a, d] 18.7±2.2	0.028*
Residence	Rural Urban	10(50%) [a] 10(50%)	13(65%) [a] 7(35%)	14(70%) [a] 6(30%)	10(50%) [a] 10(50%)	0.452
Education	Elementary Primary Secondary	13(65%) [a, c] 3(15%) 4(20%)	14(70%) [b, c] 5(25%) 1(5%)	18(90%) [a] 0(0%) 2(10%)	10(50%) [b, c] 6(30%) 4(20%)	0.054

Demographic data of all participants shows that no significant differences among all studied groups as regard demographic data except significant higher BMI in epileptic children treated with old antiepileptic drugs than other groups with p value=0.028.(Table 1).

Table (2): Clinical data of epileptic children

		Group II	Group III	Group IV	P value
		N=20	N=20	N=20	
Epilepsy type	Idiopathic generalized Partial epilepsy Epileptic syndromes	17(85%) [a, c] 3(15%) 0(0%)	14(70%) [c, d] 6(30%) 0(0%)	10(50%) [b, d] 8(40%) 2(10%)	0.089

Table 2 represent clinical data of all diseased groups.

Table (3): Serum lipid profile among studied groups

		Group I	Group II	Group III	Group IV	P value
		N=20	N=20	N=20	N=20	
TC	Median IQR	107.5 [a] (90.5-117.8)	117.5 [a] (105.5-134.8)	196.5 [b] (130-236)	147 [b] (115-167)	<0.001*
TG	Median IQR	109.5 [b] (80.8-133.3)	125 [b] (94.5-139.8)	175.5 [a] (152-304)	89.5 [b] (87-128)	<0.001*
LDL	Median IQR	51 [b] (34.5-55)	60.7 [c] (43-76.4)	84.7 [a] (70.4-169.4)	94.6[a, d] (69-108.2)	<0.001*
HDL	Median IQR	31 [a, c] (24-45)	30 [a] (26-37.5)	28.5 [a] (23-41)	39 [b, c] (31.4-49)	0.052
VLDL	Median IQR	21.9 [b] (16.2-26.7)	25 [b] (18.9-28)	35.1 [a] (30.4-60.8)	17.9 [b] (17.4-25.6)	<0.001*

Alsothere are significant differences among studied groups in all lipid profile parameter (except HDL) with p value among groups = (<0.001) for each (Table 3).

Table (4): Differences in lipid profile between each two studied groups

	I vs II	I vs III	I vs IV	II vs III	II vs IV	III vs IV
Serum cholesterol	0.060	<0.001*	<0.001*	<0.001*	0.007*	0.074
Serum triglyceride	0.401	<0.001*	0.787	<0.001*	0.203	<0.001*
Serum LDL	0.030*	<0.001*	0.001*	0.001*	0.011*	0.914
Serum HDL	0.797	0.607	0.098	0.588	0.011*	0.017*
Serum VLDL	0.401	<0.001*	0.787	<0.001*	0.203	<0.001*

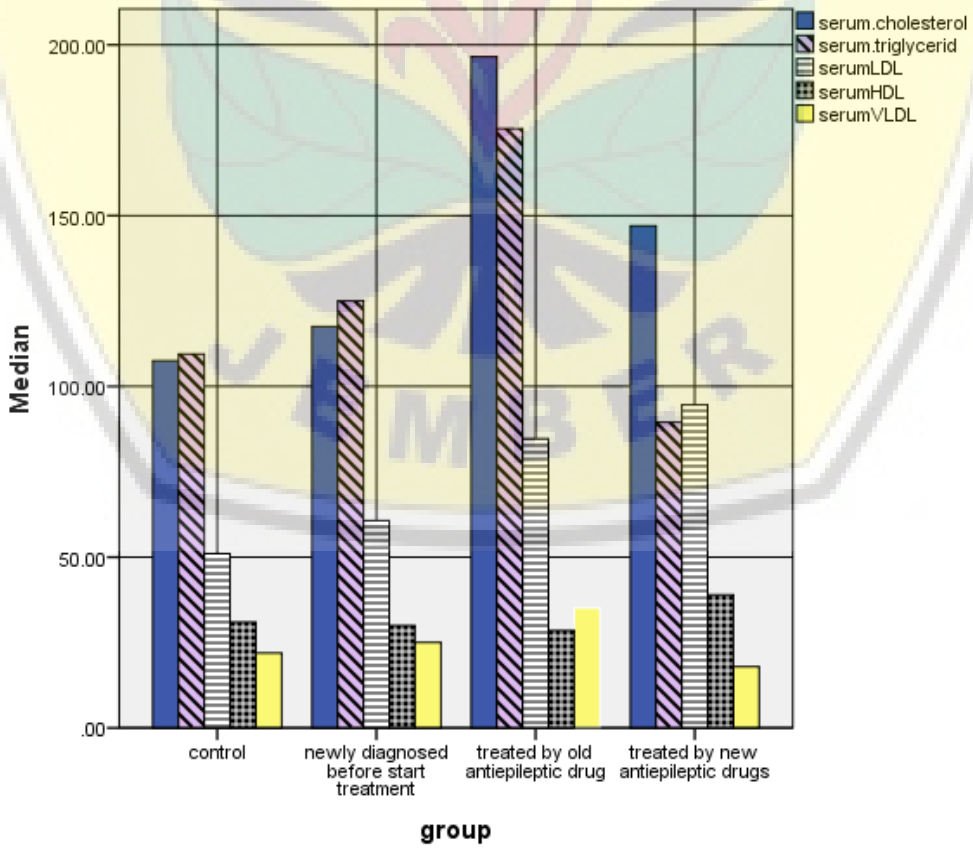

Fig (1): Differences of total lipid profile among studied groups.

There were significantly higher serum TC & LDL in Group III & IV when compared to control children and Group II, with p value (< 0.001 & <0.001) and (<0.01 & .007) for TG and p value (<0.001 & 0.001) and (0.001 & 0.011) for LDL respectively.

As regard triglyceride and VLDL serum levels they are significantly higher in group III than other groups with p value (<0.001) for each.

There is no significant difference between group II and control except in LDL serum level is significantly higher in group II than control with p value (=0.030)

While there is a significantly higher HDL in group IV than group II & III with p value (0.011 & 0.017) respectively (Table 4).

Discussion

This study was designed to evaluate the effect of old and new antiepileptic drugs and the effectepilepsy itself on lipid profile parameter ofepileptic children.

In this study we found a significant higher BMI in epileptic children treated with old antiepileptic drugs (VAP & CBZ) than control group.

This result was in accordance with **Gungor et al,[5].** who found that some drugs such as VPA and to some extend carbamazepine cause weight gain and increase BMI .

In disagreement with this result **Pickrell et al**,[6]who found that LEV was associated with significant weight gain while CBZ was not associated with significant weight gain.

In this study we found significantly higher serum TC & LDL (which is a risk factor for atherosclerosis (in epileptic children treated with antiepileptic drugs (old and new generation) when compared to control and newly diagnosed group with p value (< 0.001 & <0.001) and (<0.01 & .007) for TC and p value (<0.001 & 0.001) and (0.001 & 0.011) for LDL respectively. As regard triglyceride and VLDL serum levels they are significantly higher in epileptic children treated with old antiepileptic drugs than other groups with p value (<0.001) for each.

Similar finding was reported by **El-Farahaty et al** [7] who study the metabolic and atherogenic effects of long-term antiepileptic drugs in a group of adult Egyptian epileptic patients.;He found Significant higher LDL and significantly larger diameter of common carotid artery intima-media thickness in each drug-treated group (old and new)versus control group .and he conclude that long-term monotherapy treatment with valproate, carbamazepine had altered markers of vascular risk that might enhance atherosclerosis, whereas levetiracetam exerted minimal effect.

Also similar finding was reported by **Yamamoto et al,**[8] who found that epileptic patients on VPA or CBZ were associated with a higher non-HDL-C, but he found that an elevated non-HDL-C level was associated with increasing age, increasing BMI and male gender and use of inducer drugs, treatment with levetiracetam had little influence on the lipid profile and he recommend routine monitoring of the non-HDL-C level when using VPA and inducers, especially CBZ. (Yamamoto et al., 2016)

In disagreement with this result was **Nishiyama et al**.,[9] who found that there were no significant changes in total cholesterol, LDL in patient before starting Carbamazepine (as old antiepileptic drug) by 1m and after staring them by 6 m (Nishiyama et al., 2019)

Płonka-Półtorak et al,[10] also found that no significant difference between patients on the valproate (VPA) treatment and controls for total cholesterol (CHOL), low-density-lipoprotein cholesterol (LDL).

We also found that significantly higher HDL (which is considered a protective factor against atherosclerosis, cardiovascular or cerebrovascular disease)in epileptic children treated with new antiepileptic drugs (LEV & OXC) when compared to newly diagnosed epileptic children and children on old antiepileptic drugs with p value (0.011 & 0.017) respectively, while no significant difference was detected between other groups in HDL level.

Attilakos et al [11] also found that LEV increase HDL and the LDL-C/HDL-C ratio was significantly decreased at 12 months of LEV treatment in children and considered LEV as a safer alternative drug for the prevention of antiepileptic drug-induced cardiovascular complications in adult life.

In disagreement with us **Kim et al,**[3] who found that patient treated with (LEV and OXC) after 6-month period of monotherapy not significantly change, HDL-C levels.

We found that there is no significant difference in lipid profile between newly diagnosed epileptic children and control except in significantly higher LDL serum level than control with p value (=0.030).

This result was in accordance with the result of (Arend et al., [12]how found that higher lipid profile levels were observed in the patients with epilepsy than controls

Conclusion

From the present study we can conclude that old generation antiepileptic drugslike VAP and CBZ are strongly associated with dyslipidemia whereas OXCand LEV associated with altered lipid profile and HDL which is a protective factor against atherosclerosis. Therefore, the serum lipid profile level should be regularly monitored in patients undergoing therapy with antiepileptic medicines and we prefer selection of new AEDs in treatment of epileptic children to overcome dyslipidemic side effect occurs with old AEDs.

The Institutional Ethics Committee approved this study of the School of Medicine, Minia University, Egypt and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

Determinant of Less than Two Years Birth Interval among Multiparous and Reproductive Age in Kabupaten Tulungagung, East Java, Indonesia

Mienna Yuniarti[1], Agus Sulistyono[2], Budi Utomo[3]

[1]Master Degree of Reproductive Health Science, Faculty of Medicine Universitas Airlangga Surabaya, [2]Departement of Obstetrics and Gynaecology, Dr. Seotomo Hospital Surabaya, [3]Departement of Public Health, Faculty of Medicine Universitas Airlangga Surabaya Indonesia

Abstract

Background: Birth interval is the length of time between two successive live births. Previous research revealed that birth intervals <2 years had a higher risk of low birth weight (LBW) events compared to longer labor intervals (Demelash et al., 2015). Tulunggung is one of the districts in East Java with an increasing LBW incidence, from 2016 about 27.36% and increase in 2017 to 30% of the number of births.

Objective: The aim of this study was to determine the determinants of risk factors for birth intervals <2 years in Tulungagung.

Method: This research is a retrospective case-control observational analytic study and consisted of 80 case and 80 control samples taken with purposive sampling.

Result: Multivariate analysis showed 5 factors as determinants of birth intervals <2 years, namely: not planning a pregnancy (OR = 21.28; 95% CI (0.014-0.155), duration of breastfeeding <16 months (OR = 11.49; 95% CI (95% CI) 0.028-0.270), do not use contraception (OR = 6.33; 95% CI (0.054-0.466), ideal size number of children> 2 (OR = 5.85; 95% CI (0.055-0.533) and family income < UMR (OR = 4.55; 95% CI (0.068-0.717). The highest probability is 81.6%, namely that the probability of the occurrence of birth intervals <2 years in multiparous women of childbearing age in Tulungagung is 81.6% if the mother is in a condition no contraception and breastfeeding duration <16 months.

Conclusion: Planning for pregnancy, duration of breastfeeding, use of contraception, ideal size number of children and family income are determinants of birth interval <2 years in Tulungagung.

Keyword: *Determinant, < 2 years Birth intervals, Tulungagung.*

Introduction

Birth interval is the length of time between two successive live births[2]. Depend on the Indonesia Demographic and Health Survey 2012 showed the birth intervals less than 2 years about 14,9%[15]. Previous research revealed that birth intervals <2 years had a higher risk of low birth weight (LBW) events compared to longer birth intervals[8]. Research by Meihartati (2016) also concluded that birth intervals were associated with LBW, with 75.8% of LBW cases occurring at <2 years birth intervals[16]. One of the health problems caused by the <2 years birth interval is the incidence of low birth weight (LBW). LBW is one of the causes of infant death and other causes including labor trauma asphyxia, tetanus neonatorum (TN) infection, congenital abnormalities and so forth[11].

We all know that infant mortality is an indicator of the health status of the Indonesian people. Tulunggung is one of the districts in East Java with an increasing BBLR incidence, from 2016 amounting to 27.36% and experiencing an increase in 2017 to 30% of the number of births[3].

Previous research analyzed the determinants of birth distance factors <3 years based on the 2012 IDHS results. The results show determinants of short birth distance (<36 months/3 years) including maternal education, maternal age during last pregnancy <20 years, maternal age at last delivery < 20 years, plans to have more than two children, use simple contraception, not use contraception and the survival of the previous child[1,15]. The results of other studies in Ethiopia added a determinant of birth distance <3 years, including a history of breastfeeding less than 24 months, the sex of the child previously female, poor health index[10,12].

Efforts that can be made to reduce births, reduce health problems, reduce the incidence of LBW and infant mortality are by controlling the risk factors, namely by regulating and optimizing labor intervals.

Material and Method

This research is an observational analytic with case-control design. The population in this study were multiparous women of childbearing age who had a history of recent labor with an interval of <2 years as a case population and a 2-5 year delivery interval for the control population. The research sample consisted of case and control samples. A total of 80 case samples and 80 control samples were taken from 2 puskesmas with purposive sampling. This study uses primary data sources. Data obtained by questionnaire.

The dependent variable is the interval of birth <2 years and the independent variable is the age of the mother at marriage, the age of the mother during previous labor, maternal education, mother's occupation, history of contraception use, history of breastfeeding <16 months, hus Band's age at marriage, hus Band's education, hus Band's occupation, family income, pregnancy planning, parity, history of child mortality, religion, ideal size of the number of children and information education and counseling/IEC) of health workers. The analytical method used include univariate analysis, bivariate with chi square and multivariate with multiple logistic regression. Variables that are stated in the multivariate model are the variables which on the bivariate exam have a value of p <0.25.

Findings: The birth interval <2 years in Tulungagung is influenced by several factors. The proportions of factors related to birth intervals in Tulungagung and the results of the bivariate analysis are shown in Table 1 below:

Table 1. Proportion of influential factors and bivariate analysis results with chi square

Based on the results of the bivariate analysis shown in table 1, there are five variables associated with birth intervals in Tulungagung with p <0.005 including: planning for pregnancy, duration of breastfeeding, use of contraception, IEC from health workers about planning birth and family planning and ideal size of the number of children.

On the variable of religion and history of child mortality analysis cannot be done because the data is constant, namely all respondents are Muslim and do not have a history of children who died. The independent variable which is a candidate for multivariate analysis is a variable that has a p value <0.25. These variables are: Hus Band's age at marriage, hus Band's education, monthly family income, parity, pregnancy planning, maternal employment status, duration of breastfeeding, use of contraception, IEC officers about planning birth and family planning and the ideal size of the planned number of children.

Table 2: Determinant of < 2 years birth interval, Multivariate analyzed

No.	Variabel	β	p	Odd Rasio	CI 95%
1	**Pregnancy planning** - No - Yes	-3,064	0,001	0,047	0,014-0,155
2	**Breastfeeding** - <16 months - ≥16 months	-2,441	0,001	0.087	0,028-0,270
3	**Use of contraception** - No - Yes	-1,845	0.001	0,158	0,054-0,466
4	**Ideal size of children** - More - Two	-1.769	0.02	0,171	0,055-0,533
5	**Family income** < Minimun wage ≥ Minimun wage	-1,514	0,12	0.220	0,068-0,717
Constanta		4,898	0.001	134,075	

The logistic regression test results as shown in table 2 can be concluded that the determinants of birth interval <2 years in Tulungagung are the use of contraception, duration of breastfeeding, pregnancy planning, ideal size of the number of children and family income. Mothers who do not use contraception 6,33 times ($OR_{risk\ factor}$ = 6,33; 95% CI = 0,054-0,466) are more at risk of giving birth at intervals <2 years compared to mothers who use contraception. Respondents who breastfeed <16 months 11,49 times ($OR_{risk\ factor}$=11,49; 95% CI = 0,028-0,270) are more at risk of giving birth at intervals <2 years than mothers who breastfeed >16 months. Respondents who did not plan for pregnancy 21,28 times ($OR_{risk\ factor}$= 21,28; 95% CI = 0,014-0,155) were more at risk of giving birth at intervals <2 years than mothers who planned their pregnancy. Respondents who planned more than two children 5,85 times ($OR_{risk\ factor}$ = 5,85; 95% CI = 0,055-0,533) were more at risk of giving birth at intervals <2 years than mothers who planned the number of two children. Family respondents who earn <UMR 4,55 times ($OR_{risk\ factor}$ =4,55; 95% CI = 0,068-0,717) are more at risk of giving birth at intervals <2 years than mothers whose family income> UMR. Respondents who did not use contraception 6,33 times more at risk of giving birth with a birth interval <2 years compared with those using contraception. The results of this study are in line with the results of research by Kurniawati & Prasetyo (2014) which states that mothers who use traditional contraception have a 1,47 times higher risk of experiencing short labor intervals compared to women who use modern contraception. Mothers who do not use contraception have a 1.5 times higher risk of experiencing short labor intervals than women who use modern contraception. Apart from that, because one of the objectives of the family planning program is to regulate birth spacing, namely by preventing pregnancy[4]. It is known that non use of family planning and contraceptive failure are among the main causes of unintended pregnancy. It was reported that 78% of unwanted pregnancies were attributable to contraceptive non use, incorrect use, or method failure in Ethiopia[17].

Respondents who breastfeed <16 months 11,49 are more at risk of giving birth at intervals <2 years than mothers who breastfeed >16 months. The results of this study are in line with research by Hailu & Gulte (2016) which states that the duration or duration of breastfeeding a previous child is significantly related to short labor intervals. This is because the hormonal regulatory mechanism experienced by breastfeeding mothers affects the fertility of the mother[6]. Respondents who did not plan for their pregnancy were 21,28 times more at risk of giving birth at intervals of <2 years than mothers who planned their pregnancies. This is in line with previous studies in Denmark that mothers who planned their pregnancies might have longer labor intervals than mothers who did not plan their pregnancies. This is supported by several considerations, namely: maternal health, infant health conditions and family finances[12].

The importance of planning both pregnancy and childbirth, especially the distance between deliveries. Because with good planning, it is expected that the mother and hus Band are really ready to have a baby again. Readiness here is not only readiness in terms of cost but also more in physical and mental readiness.

Respondents who planned more than two children were 5,58 times more at risk of giving birth at intervals <2 years than mothers who planned two children. This is in line with the results of research by Kurniawati & Prasetyo (2014) which states that the ideal size of the number of children is related to the delivery interval.

Couples who want more than two children have a risk (1.34 times) higher for short labor intervals compared with couples who want the number of children less than that or just enough. This shows that indeed the value that is believed, greatly affects the individual making a decision or acting.

Respondents whose family income <UMR 4,55 times more risk of giving birth at intervals <2 years than mothers whose family income> UMR. This is in line with the results of research by Abdel-Fattah., Et al (2007) which states that the economic status of the family is a strong predictor of labor intervals. Research conducted in Saudi Arabia indicates that short labor intervals are independently influenced by low family income.

Conclusion

After analyzing the logistic regression test, it was found five factors which were discriminatory labor intervals <2 years in multiparous women of childbearing age in Tulungagung District, namely pregnancy planning ($OR_{risk\ factor}$ = 21,28; 95% CI = 0,014-0,155), the ideal size of the number of children ($OR_{risk\ factor}$ = 5,85; 95% CI = 0,055-0,533), use of contraception ($OR_{risk\ factor}$ = 6,33; 95% CI = 0,054-0,466), family income ($OR_{risk\ factor}$ = 4,55; 95% CI = 0,068-0,717) and duration of breastfeeding <16 month ($OR_{risk\ factor}$ = 11,49; 95% CI = 0,028-0,270).

The highest probability value is 92.6% and the lowest is 3.4%. From these two extreme values, it can be concluded that the probability of birth interval <2 years in multiparous women of childbearing age in Tulungagung Regency is 92.6% if the mother is in the following conditions: planning Number of children> 2, unplanned pregnancy, breastfeeding <16 month and do not use contraception.

The Effect of Top Management Commitment and Environmental Strategy on Environmental Management Accounting Health Institutions in Indonesia

Miswaty[1], Muslich Anshori [2], Basuki[2]

[1]Ph.D. Student in Airlangga University Surabaya, Indonesia, [2]Airlangga University Surabaya, Indonesia,

Abstract

Purpose of this research paper is to report the results of research that explain the relationship between environmental strategies and Top management commitment to the adoption of Environmental management accounting (EMA). In particular, EMA practices in health institutions in Indonesia. The research method of quantitative correlation from the theory of Natural Resouce Base View and identify environmental strategies and Top management commitment influence the rate of adoption of EMA. A total of 100 managers from healthcare institutions in Indonesia participated in the survey.

The result showed that environmental strategy has a strong effect on EMA adoption of T value (2,773)> (1.96) and P value (0.005) <α (0.05), while top management commitment has a strong effect on EMA adoption of T value (4,801))> (1.96) and P value (0,000) <α (0.05). of all these, top management commitment was found to be the most powerful. Practical implications Recognizing the important role of environmental strategies and top management commitment in managing environmental problems in organizations, this study highlights the influence of leadership and the involvement of managers as a determinant of EMA adoption. Originality/ value - This paper offers a preliminary understanding from the perspective of the Natural Resource base view theory about the company's resources, namely the environmental strategy and top management commitment that influences companies in health institutions in Indonesia to adopt EMA.

Keywords: *Environmental management accounting (EMA), environmental strategy, top management commitment, Management accounting, health institutions.*

Introduction

In the current decade industrial development has increased and has brought immeasurable wealth and prosperity while also causing undesirable environmental damage in the long run such as increased pollution, global warming and toxic waste so that it becomes a very important issue for the community. This loss of future resources will undermine the foundations of business enterprises. While the significance and importance of implementing environmental management practices is widely recognized, not all companies are willing to apply environmental management practices in their daily operations management. business[1,2]

Companies need to adopt a strategy that is responsive to the environment even though it is not required by regulations because of the necessity to maintain competitiveness and economic performance. Internal organizational change needs to be done in organizations that are proactive and use environmental responsive strategies[3] . The company is expected to adopt and implement environmental management practices to reduce the negative influence of the company's activities on the natural environment[4]. Therefore environmental

management issues have become an important consideration for the community and are under pressure. In fact, the application of environmental management practices can reduce pollution levels and as such they are considered an effective method for protecting the natural environment[5,6].

Demands for obtaining different accounting information are also increasing and vice versa where interest in accounting for the environment has also increased[7,8]. However, traditional financial accounting and cost accounting fail to provide environmental information specifically environmental cost information[9]. Some researchers identified that the accounting system lacks recognition of environmental impacts does not identify investment appraisals handling environmental impacts[10]. Further environmental management accounting (EMA) has emerged to respond to these limitations. EMA is a combined approach, which provides data transitions from financial accounting, cost accounting and material flow balances to improve material efficiency, reduce impacts and risks to the environment and reduce environmental costs.

Research concerning the influence of EMA and business strategy at big companies in Australia shows that there is a positive relationship between the application of the company's business strategy EMA andhealth[11]institutions. In the Top Management Commitment research relationship, the company's environmental strategy on environmental performance with EMA as mediation shows that the company's environmental strategy influences EMA as well as the Top Management Commitment also has an influence on EMA. The results of some of these studies illustrate that EMA is a tool that provides information for companies related to the environment[12].

According to EMA research, environmental activities and practices carried out by companies largely depend on management commitment to the environment owned by the company will encourage reliable environmental performance [12]. Testing the effect of environmental strategies and top management commitment on Environmental Management Accounting (EMA) in healthcare institutions in Indonesia is observed by looking at the effect in contingency perspectives using the Natural Resource Based View (NRBV) approach.

The results of this study can be expected to provide benefits, this research adds evidence to clarify the relationship between the Environmental Strategy and Top Management Commitmet to the practice of Environmental Management Accounting (EMA) which is a follow-up study of research that examines the determinants of Environmental Management Accounting (EMA) practices[11,12]

Materials and Method

This study was conducted using a quantitative approach (questionnaire survey), because this enables researchers to obtain comprehensive information about populations and determine the effects of one variable on another. This study aims to test the hypothesis that associative forms produce accurate data based on empirical phenomena that can be measured and to test for doubts related to validity and theory through theoretical testing, building or contradicting facts and data, statistical descriptions, clarity and predictive relationships. Sample selection and data collection. The unit of analysis of this research is a medical institution company. Respondents of this study focused on company leaders or managers. The management of the company is used as respondents to assess the Environmental Strategy, Top Management Commitment and Environmental Management Accounting.

Data analysis in this study uses simple linear regression analysis because the model in this study uses only one independent variable. The following is a linear regression model that is run.

$$EMA = a + b1SL + b3TMC + e$$

Description:
EMA = Environmental management accounting
TMC = Top management commitment
SL = Environmental Strategy

Findings: Analysis of the Effect of Environmental Strategy and Top Management on Environmental management accounting.

Table 1. Results of Regression Analysis Regression

Variables	Coefficient	T value	Significance
(Constant)	0.749	1,776	0.034
SL	0,293	2,773	0.005
TMC	0,483	4,801	0,000
a dependent variable: EMA dependent.			
Test F		30,564	0,000
R Square		0,485	
Cronbach's Alpha		0,834	

The results of the linear regression analysis in the above table can be written systematically the equation is as follows:

EMA = 0.749 + 0.293 SL + 0.483 TMC

Based on the above equation it can be interpreted that the SL regression coefficient, which is an environmental strategy, shows a positive coefficient of 0.293 thus it can be seen that the higher the environmental strategy, the higher the application of EMA. While the TMC regression coefficient, namely top management commitment, shows a positive coefficient of 0.483 thus it can be seen that the higher the top management commitment, the higher the application of EMA.

Discussion

Constants of 0.749 with positive parameters indicate that SL and TMC will increase the application of EMA. The results of this study support previous research which states that the environmental strategy of acompany health institution will encourage the adoption of EMA to be more aligned with the company's goals on environmental issues as well as Top management commitment play a role in EMA adoption. Management that provides support for the impact of company activities on the environment uses EMA to obtain financial information related to environmental costs for use in environmental management decision making.

In accordance with previous studies the results of this study support the argument that there are positive and significant effects of environmental strategy and top management commitment on the adoption of Environmental Management Accounting. The environmental strategy is a guide to achieving environmental management practices such as Environmental Management accounting because the information provided by EMA facilitates the company's environmental management activities. Likewise, the literature on top management commitment states that in the context of EMA[13], while leadership and top management support is very important to ensure the understanding and commitment of the entire organization to environmental issues[14].

The results of this study support research that environmental strategies influence the adoption of EMA Likewise the Top management commitment variable influences EMA in line with research[3,11,12]. Environmental strategy planning as part of an eco-control package can improve the company's environmental and economic performance through the use of EMAIn addition, the environmental strategy motivates companies to adopt eco-design.[15]

From the description above it can be concluded that the adoption of EMA in the company being the research sample has shown optimal results and is influenced by the environmental strategy and top management commitment. Therefore, the environmental strategy and top management commitment as well as the implementation of EMA must be continuously improved[16, 17,18]

Conclusion

Environmental strategy variables influence the implementation of EMA. This is indicated from the significance value of 0.005 <0.05. Top management commitment variable influences EMA. This is indicated from the significance value of 0,000 <0.05.

Comparative Study Using Biomimetic Remineralization Versus Fluoride Varnish in Management of White Spot Lesion in Post Orthodontic Treated Patient: Split Mouth Randomized Clinical Trial

Mohamed Farid Riad[1], Rasha Raafat[2], Aalaa Mohamed Nabil Amin[3]

[1]Professor of Conservative Dentistry, [2]Assistant Professor of Conservative Dentistry, Faculty of Dentistry, Cairo University, [3]Assistant Lecturer in MTI University

Abstract

Background: The milky color of white spot lesions impairs dramatically the esthetic appearance thus reducing satisfaction of orthodontic therapy, making their treatment become nowadays mandatory[1]

Objectives: The aim was to compare the effect of color change between remineralizing agent and guided enamel regeneration in treatment of white spot lesion after orthodontic treatments.

Materials and Method: In split mouth design, white spot lesions in anterior teeth of post orthodontic debanding patients received randomly either Curodont Repair or Duraphat Fluoride varnish single dose, both materials were applied according to the manufacturer's instructions. White spot lesions were evaluated before and after 3, 6 months follow up periods by two blinded assessors to assess patient satisfaction using VAS score and color change by Vita Easyhshade.

Results: Friedmann test was used to compare between follow-up periods for visual analogue scale (VAS). The patient satisfaction showed statistically significant difference after application of Curodont Repair for 3 & 6 months follow up periods; in contrast with the results of Duraphat which record patient un satisfaction for color change of white spot lesion. However repeated ANOVA was used to show the effect of materials and follow-up periods. The better color change results using Curodont Repair in treatment of white spot lesion.

Conclusion: Curodont Repair offer a therapeutic option for enamel regeneration, it is designed to deliver a the scaffold for improved remineralization of the lesion body forming new enamel which in turn enhance the masking of white spot lesion.

Keywords: *White spot lesions- Curodont repair-color change.*

Introduction

Cosmetics and esthetics are current trends of our society as more and more patients are demanding for minimally invasive cosmetic enhancement without anesthesia, drilling and less expensive restorations. This technique may be considered as micro invasive treatment of smooth surface white spot lesions and also one that allows for the recovery of natural tooth appearance [1]

Enamel regeneration is however particularly challenging as mature enamel is a cellular and does not resorb or remodel itself unlike bone or dentin Advances in tissue engineering method have yielded biomimetic

e-mail: aalaanabil@gmail.com

method that have demonstrated a strong potential for regenerating the hierarchical enamel microstructure[2,3].

Due to the limited evidence based information in literature regarding the self-assembling peptide p11-4 in management of white spot lesion[2,] it was found that, it will be purposive to evaluate the clinical performance of this newly introduced biomimetic remineralization material using a randomized clinical trial to test the null hypothesis that self-assembling peptide p11-4 will have the same clinical performance as conventional high fluoride varnish in management of white spot lesion after orthodontic treatment.

The aim of this study

The aim of this study was to compare the effect of color change between remineralising agent and guided enamel regeneration in treatment of white spot lesion after orthodontic treatments.

Materials and Method

Method:

1. **Outcome data collection:**

- **Perimary outcome: assessment of patient satisfaction:** Patient satisfaction was measured using visual analogue score (VAS) scores. The mean and standard deviation for the VAS scores of thepatients recorded preoperatively

  Secondery outcome: assessment of color change of white spot lesions: Visual color assessment was performed using the Vita Easyshade Spectrophotometer Compact (Vita Zahnfabrik, Bad Sa¨ckingen, Germany)[4]. Each white spot lesion was measured by holding the probe tip at a right angle to the surface and the values were reported. To minimize measurement errors, the assessments were repeated three times and the mean values of three consecutive measurements were recorded for each area. Only the L* value was captured in this study. As shown in figure (1)

2. **Material application:**

a. Intervention: Curodont repair was applied according to the manufacturer's instructions. Teeth were swapped with 2% NaOCl for 20 seconds, then rinsed 20 seconds and gently air-dried. Teeth were etched with 35% Phosphoric acid (Dental Technologies, Inc., USA) for 20 seconds and subsequently rinsed with water for 20 seconds and under moisture control[5]. Cuorodont repair applicator unit was activated by pushing the two cylinders together, single white spot lesion was treated by gently pressing the tip directly onto the tooth surface as shown in Solution was allowed for five minutes to diffuse and until the tooth surface appears dry. .as shown in figure (2 a, b, c)

b. Comparator: Colgate® Duraphat ®Varnish Single Dose 5% NaF (Woelm Pharma GmbH, Germany) was applied according to the manufacturer's instructions. Tooth surfaces with white spot lesions were swapped using a miniature cotton brush applicator dabbed repeatedly onto the tooth surfaces without contacting soft tissues as shown in after a few minutes a thin and clear layer is formed.

Findings: Friedmann test used to evaluate the effect of two remineralizing agents application (Curodont Repair and Duraphet) on the patients satisfaction recorded by VAS score values. Median (M) and 95% Confidence Interval (CI) values were calculated and summarized in **(Table 1)** and graphically drawn in **(Figure 3)**. The Highest M and CI values were recorded after application of Curodont Repair by 3 and 6 months whereas the lowest values were recorded before remineralizing agents application.

Data statistically described in terms of mean values and standard deviation (SD). Repeated ANOVA test used to evaluate the effect of two remineralizing agents (Curodont Repair and Duraphet) on the color change of the white spot lesions in 2 different follow-up periods (3 months and 6 months) and compare them to the color change of these white spots before their application. **(Table 2)** and **(Figure4)** showed a comparison of the total L* values (Mean ± SD) as a function of treatment of white spot lesions with 2 remineralizing agents (Duraphate and Curodont).

Discussion

White spot lesion is an optical phenomenon due to subsurface tissue loss. Surface features of active initial enamel carious lesions show widened intercrystalline spaces with lower interprismatic mineral content in the surface layer [4, 6,7].

Based on today's understanding of dental bio mineralization process, new efforts have been developed

to produce synthetic analogs of non-collagenous proteins, which are involved in the events of nucleation and growth of hydroxyapatite crystals in hard tissues[8.4].

Recently a rationally designed self-assembling peptide p11-4 was introduced to the market. It is designed to enhance the remineralization on enamel subsurface lesions [9]. P11-4 is an eleven- amino acid peptide that undergoes well characterized hierarchical self-assembly into three-dimensional fibrillar stable scaffolds in response to specific environmental triggers [10], offering a new generation of well-defined bio polymer[11]. Assembled P11-4 forms scaffold- like structures with negative charge domain on its surface, these domains attract Ca2+and other mediated ions, leading of de novo precipitation of hydroxyapatite crystals [9,12].

The main bulk of available evidence represented controlled clinical trials of using self-assembling peptide P11-4 as a remineralising agent to arrest initial carious lesions (white spot lesions) [13]. On the other hand, clinical trials about the efficacy of self-assembling peptide P11-4 in masking the color of white spot lesions for achieving the patient satisfaction appears to be insufficient for clinical guidance [13].

Active white spot lesions usually have a better prognosis to recover the translucency of the enamel than arrested white spot lesions because of their porosity and therefore easier penetration of calcium phosphate ions [14]. Nearly, half of white spot lesions might be arrested after debanding by 2-6 months, thus additional intervention after this period will mostly result in poorer esthetic [14]. Also participants were selected in this study had no systemic diseases or following concomitant medication reducing the salivary flow rate as it often shows a greater caries risk incidence than those of physiological reduced rates[15].

In this study a high concentration at repeated intervals might have toxic effect although [16] in their study on fluoride varnish, reported minimal risk of acute toxic reactions. The three and six month duration of this study permitted evaluation of demineralization of a single-dose fluoride varnish with high fluoride concentration in vivo Fluoride varnish adheres to the tooth surface in a thin layer and releases fluoride for a period of 5–6 months [17]. Regardless of its high fluoride concentration, rapid setting time can be performed once upon contact with saliva, hence preventing risk of ingestion. Moreover, only a small dosage is used and less the use of a tray, thus shortening the amount of clinical chair time and maximizing application safety[18].

Curodont repair was applied according to the manufacturer's instructions. Teeth were swapped with 2% NaOCl for 20 seconds; the rationale for treating enamel with oxidizing agents as sodium hypochlorite is to remove surface organic pellicle [19] increasing the diffusion of calcium and phosphate ions into the enamel subsurface lesion[20,20,] then subsequently rinsed with water for 20 seconds and under moisture control [5.22].

The superiority of patient satisfaction (VAS score) values after Curodont Repair application might be due using split mouth design, so the patient comparing the contralateral affected teeth. [24/25]considered fluoride deprives the masking of white spot lesions, This was disagreement with [18]who reported a high-concentration of Duraphat fluoride varnish was shown to be effective in reversing the color of white spot lesions at 3-month and 6-month follow-up periods after debonding. But the application of fluoride varnish was every month.

Optically there are two types of scatters in enamel; small enamel crystallite and large enamel prism (uniaxial) they are responsible for translucency appearance of the enamel [25], The translucency of the enamel is determined by the refractive index of the hydroxyapatite and the water accumulates in the intercrystalline spaces [26] Based on these facts it was assumed that the Curodont Repair had the ability to organize enamel rods and arrange the enamel crystals homogeneously with a clear outline and hence Curodont Repair can improve the color change.

This was in agreement with studies done by[9,26,12&16], where they also found P11-4 able to induce biomimetic regeneration of early caries lesion. For these reason it was assumed that the application of Curodont Repair on white spot lesion after orthodontic brackets debanding can improve the color change. Moreover [13] and [22]were in agreement with the results of the current study as the Curodont could mask & reversing the white spot lesions. They measured the colorimetric change (ΔE) using spectrophotometer in artificial white spot lesions. There are no recorded clinical studies evaluated the color change after application of Curodont Repair.

The highest color change results showed highest L* value (low color change). This is may be due to effect of Duraphat varnish limited to the outer 30-40µm of enamel lesion (subclinical) and not effective at deeper level of the body of the lesion.[22]

The demineralized enamel was disorganized, with loss of structural characteristics and after fluoride application amorphous crystal or particles scattered on the surface or lines of remineralization along the prismatic borders. Based on this fact it was assumed that blocking of the surface layer affect the color change of the white spot lesion negatively through alteration of refractive index of enamel. This was in agreement with study done by [7,22], where they also fond Duraphat fluoride varnish, under in-vitro conditions, inhibited further lesion progression but could not mask the unfavorable appearance of white spot lesions considerably. Whereas disagreement with some researchers which conjectured that low doses of fluoride were effective in controlling the regression and remineralization of lesions in order to prevent hyper mineralization and those high doses were recommended to inhibit initial lesion formation and excessive quantities of fluoride may be detrimental to their subsurface remineralization although optimum fluoride doses and delivery mechanisms have yet to be established.[26]

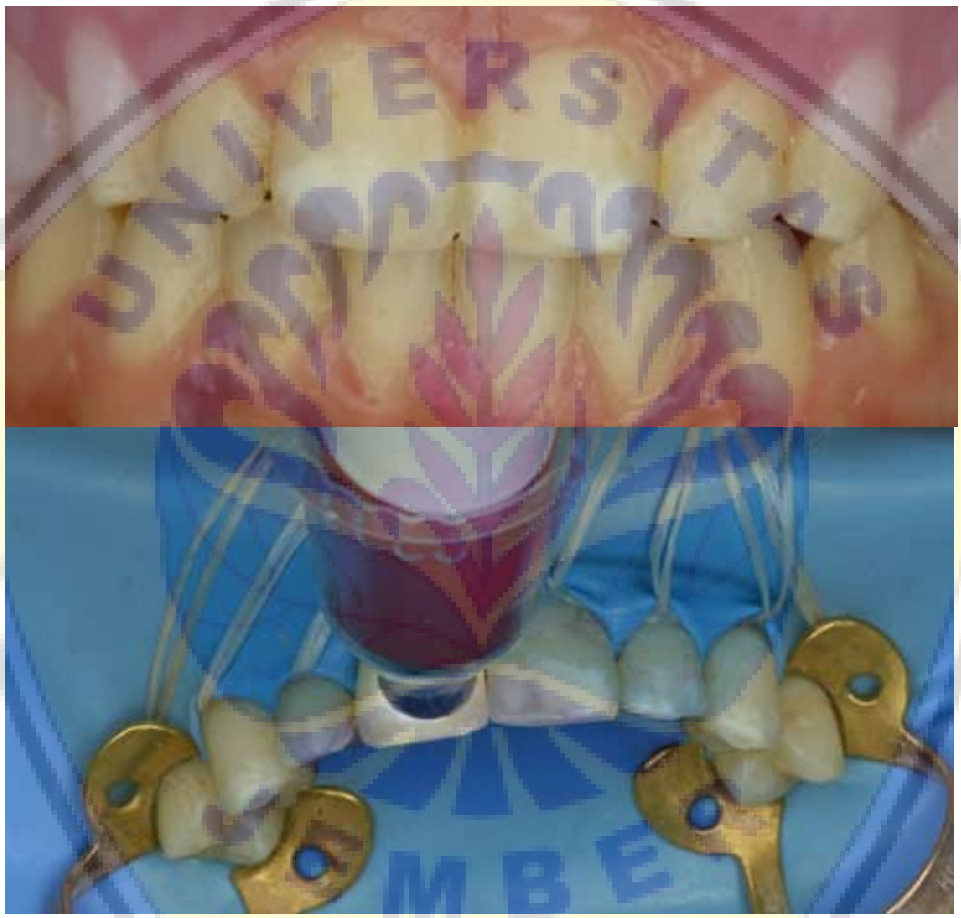

Figure (1): Calibration of L* Value:

Figure 2a, b, c: Etching with 35% Phosphoric acid., Cuorodont repair applicator unit activation., Application of Cuorodont repair.

Table 1: Median and 95% CI Values for different tested remineralizing agents within each follow-up period:

		Before			3 Months			6 Months			p-value

Conclusion

Under the limitations of the current investigation, the following Conclusions were evident: 1- Curodont Repair (self- assembling peptide P11-4) act as a biomimetic remineralization and offer a therapeutic option for enamel regeneration, it is designed to deliver a the scaffold for improved remineralization of the lesion body forming new enamel which in turn enhance the masking of white spot lesion.

Duraphat fluoride varnish considered as a remineralizing agent and very low efficacy on masking of white spot lesion.

Complications of Intralesional Steroids in Management of Infantile Hemangioma

Moutaz Ragab[1], Mohamed Hamed Abouelfadl[1], Ahmed Arafa[1], Mahmoud M. Marei[1]

[1]Department of Surgery, Pediatric Surgery Unit, Cairo University Specialized Pediatric Hospital (CUSPH), Faculty of Medicine, Cairo University, Cairo, Egypt

Abstract

Objective: Infantile Hemangiomas can result in severe functional and aesthetic disorders. Many treatment options are available for such condition. In this study, we present our center experience with intralesional steroids injection in the management of infantile hemangioma. Method: This study is a retrospective review of a cohort of 25 patients who were presented with IHs to our center from January 2014 to January 2015. A standardized set of data for each patient was recorded in a sheet including clinical history, patients' demographic data, clinical response, side effects and follow up visits. Colored photographs were taken for each patient at the first visit, throughout the treatment course and after finishing treatment. All the cases were treated with intralesional injection of Triamcinolone acetatein dose of 0.5mg/kg/dose once every 4-6 weeks, for 6 cycles By the same operator. Results: Twenty-five patients were managed with serial injections of intralesional Triamcinolone acetate with a mean age of 11 months. The average number of sessions was 5.2 ±0.79. Eighteen (72%) out of the 25 patients showed >50% response complete response. The adverse effects recorded; two cases (8%) showed signs of infection, bleeding from the puncture site occurred in 1 case (4%), 2 cases showed subcutaneous fat atrophy (8%), 3 cases showed hypopigmentation of the skin surrounding the lesion (12%).

Conclusion: Intralesional corticosteroids injection is an effective and safe modality for treating IHs; yet, we do recommend that we should use them in bulky, isolated lesions away from the face and bony prominences.

Keywords: Steroids; Intralesional injection; Infantile Hemangioma.

Introduction

Infantile hemangiomas (IHs) are the most common soft tissue tumors of infancy, occurring in 4% to 10% of children under 1 year of age, female infants are three to four times more likely to suffer from IH as male infants.[1]

Within the first weeks of life, they enter a phase of rapid growth lasting for 3 to 6 months which may go on for 24 months. A period of stabilization for a few months follows with spontaneous involution usually occurring in several years.[2]

However, problematic hemangiomas occur when they ulcerate, have massive growth, cause disfigurement, or impact normal function or cosmetic development. Common locations for problematic hemangiomas include the face, ear, orbit and airway. These hemangiomas subsequently require early and aggressive treatment for ideal functional and cosmetic outcomes. Moreover, ulcerated IHs usually requires treatment. Corticosteroids have been considered the first-line therapy for sever or complicated IHs.[3]

Other treatments including interferon alpha, Vincristine, laser therapy, topical Imiquimod and surgical excision have been reported to be effective

alternatives However; all have potential side effects or unknown long-term safety.[4]

In this study, we present our center experience with intralesional steroids injection in the management of infantile hemangioma, focusing on post injection complications.

Material and Method

This study is a retrospective review of a cohort of 25 patients who were presented with IHs to the vascular anomalies' clinic at the department of Paediatric Surgery of a tertiary referral university-based children's hospital from January 2014 to January 2015.

A standardized set of data for each patient was recorded in a sheet including age, sex, site and size of the lesion, clinical history, dosage and timing of injections, clinical response, side effects and follow up visits.

Colored photographs were taken for each patient at the first visit, throughout the treatment course and after finishing treatment. The diagnosis was established as an IHs after clinical evaluation by a pediatric surgery consultant and confirmed by radiological studies in the form of doppler ultrasonography (US) and magnetic resonance imaging (MRI).

The treatment protocol was: All the cases were treated with intralesional injection of Triamcinolone acetatein dose of 0.5mg/kg/dose once every 4-6 weeks, for 6 cycles. We injected the drug under complete aseptic conditions, slowly at a low pressure with a 3-mL syringe and 25-gauge needle. Before injection aspiration was done all the cases were injected by the same operator.

Clinical response was evaluated according to the following criteria: complete response (complete disappearance of vascular tissue), marked improvement (>70% disappearance of tissue), moderate improvement (40–70% of vascular tissue), slight improvement (<40% disappearance of vascular tissue) and no response. [5] Complications were recorded as well.

Findings: Twenty-five patients were managed with serial injections of intralesional Triamcinolone acetatein dose of 0.5mg/kg/dose once every 4-6 weeks, for 6 cycles. with a mean age of 11 months (range from 6 months to 24 months). Ninemales and 16 females were included in the study. Regarding the site of the lesions, twelve out of 25(48%) occurred in the head and neck region, six cases (24%) in the lower extremities, seven cases (28%) in the trunk. The mean follow-up was 7 months (range from 3 to 12 months). The average number of sessions was 5.2 ±0.79.

Regarding the clinical response; ten (40%) out of the 25 patients showed a complete response. Marked improvement was detected in 8/13 (32%). Four cases (16%) showed moderate improvement and 2 case (8%) recorded a slight response. Only one case (4%) showed no response to treatment.

The adverse effects recorded; two cases (8%) showed signs ofinfection in the form of epithelial sloughing and ulceration with purulent discharge, bleeding from the puncture site occurred in 1 case (4%), 2 cases showed subcutaneous fat atrophy (8%), 3 cases showed hypopigmentation of the skin surrounding the lesion (12%)(Fig. 1), while 17 patients tolerated the drug adequately (68%).

Discussion

Despite being self-limited and benign lesions in children, IHs may result in psychosocial stress for parents because the duration of the spontaneous regression is unpredictable. For decades systemic corticosteroids were the mainstay for treating IHs and currently Propranolol is the accepted first line of management for proliferating capillary hemangiomas. However, reported side effects of systemic propranolol encourages us to search for other treatment modalities. [6] In 1982, Kushner used local steroids for treating hemangiomas for the first time ever.[7]

In our study, we demonstrated 72% (18/25) more than 50% response and an overall response 96% (24/25) which is comparable to other studies, Gangopadhyay et al. reported that overall response rate was 88.6% with administration of intralesional triamcinolone.[8] Another two studies also showed response rates of up to 90% with intralesional corticosteroid treatment. [9, 10]

Local complications of Intralesional corticosteroids include fat and/or dermal atrophy, hypopigmentation and a more serious but rare complication of intralesional corticosteroid therapy occurs in lesions of the upper eyelid, is retinal artery or vein occlusion. This complication likely results from a combination of high injection pressures (causing retrograde flow of the drug from the eyelid toward the apex of the orbit) and excessive injection volume.[11]

In our series the adverse effects recorded were; 1 case had bleeding post injection (4%), it was from the puncture site of the needle and it was controlled by compression. 2 cases developed infection (8%), that was spontaneously drained, we did a swap culture and gave antibiotics accordingly and repeated irrigation with saline. 2 cases showed subcutaneous fat atrophy (8%), 3 cases showed hypopigmentation of the skin surrounding the lesion (11%) and for the last couple of complications we reassured the parents and just followed them up and there was gradual improvement in the degree of fat atrophy. while 17 patients tolerated the drug adequately (68%).

Concerning subcutaneous fat atrophy pathogenesis; steroids directly arrest proliferating keratinocytes and fibroblasts and alter skin lipids synthesis andproteins metabolism. Furthermore, steroids can cause local vasoconstriction, with possible thrombosis, hypoxia and consequently atrophy. Regarding the hypopigmentation, steroids probably reduce the number or activity of melanocytes. In general, treatments are not necessary and complete resolution isfrequent but requires several months. However, it can raise cosmeticand psychological problems if atrophy and hypopigmentation persist.[12]

Figure (1): 10 months old male with anterior abdominal wall IH showing area of hypopigmentation post-injection

Conclusion

Intralesional corticosteroids injection is an effective and safe modality for treating IHs; yet, we do recommend that we should use them in bulky, isolated lesions away from the face and bony prominences.

Escherichia Coli Contamination in Elementary School Snacks: A Cross-sectional Study

Nurina Vidya Ayuningtyas[1], Laila Fitria[2]

[1]Magister Student, [2]Academic Supervisor, Department of Environmental Health, Faculty of Public Health, Universitas Indonesia

Abstract

Background: Some of elementary school snacks in Indonesia are not qualified (23.82%) due to bacterial and addictive, such as prohibited preservatives and dye and 33% of the snacks were contaminated by *Escherichia coli* (*E. coli*). Many food handlers have not performed a proper hand-washing habit, only 48.3% of food handlers used soap to wash and rub their hands, including washing fingers, fingertips and wrist. There are 42.1% that do not have a good quality of cookware and cutlery and 42.1% do not have a good food-processing place.

Objective: This study aimed to observe individual characteristics of food handlers, hygiene sanitation of food handlers at elementary school canteen, quality of snacks with bacteria parameters (*Coliform* and *E. coli*) and to find out variables related to *E. coli* contamination on snacks at the canteen.

Method: The researcher applied a cross-sectional study and analysis by logistic regression multivariable supported by analysis statistic software for interview data although the quality of snack samples was analyzed in laboratory.

Findings: The samples consisted of 18 males (24.3%) and 56 females (75.7%). Most of them never attended training on hygiene sanitation and food safety (n= 59; 75.7%), showed a poor food processing and preparation (67.6%), 67.6% (n=50) of respondents performed hand-washing habit and many of them did not use gloves (n=68; 91.9%) while handling food. In months ago, some food handlers suffered from digestive tract disorder (n=15; 20.3%). Snacks with *E. coli* contamination were shown at 9.5% (n=7) and many snacks were contaminated with *Coliform* and *E. coli* used chicken in their presentation.

Conclusion: The high-risk snacks (p value = 0.024) and poor food-processing and preparation (p=0.073) have significance results with a likelihood of *E. coli* contamination on elementary school snacks.

Keywords: *E. coli, elementary school snack, high-risk snacks, hand-washing, food processing and preparation.*

Introduction

Food is an essential and important thing for humans because it contains many nutrition (protein, carbohydrate, vitamin, etc.) that can make human's body working, growing and repairing body cell[(1)]. However, food can harm humans because it is a medium for microorganism growth. Centers for Disease Control and Prevention (CDC) estimates that every year, 48 million people get sick of foodborne illnesses, 128,000 of them are hospitalized and 3,000 die. Researchers have identified more than 250 foodborne illness due to food contamination by a variety of bacteria, viruses and parasites[(2)]. *Escherichia coli* (*E. coli*) is the most founded bacteria in food[(3)] and it is an indicator for fecal

contamination in foods [4]. *E. coli* is transmitted through fecal or oral route and existing in any food[4]. Anyone can get a foodborne illness, but some people are more likely to develop one, one of them is young children[2].

There are many factors related to microbial contamination. They are unsafe sources, poor personal hygiene of food handlers, improper cooking, unqualified holding temperatures and contaminated equipment[5,6]. In addition, bacteria such as *E. coli* needs three important stuff to grow and multiply itself, that are nutrition such as protein, moisture and warmth [7,8]. Therefore, control on every factor can avoid bacterial contamination.

In 2014, 23.82% of elementary school snacks in Indonesia are not qualified cause bacterial and addictive, such as prohibited preservative and dye [9]. In 2015, 33% of elementary school snacks in Pancoran Mas District, Depok City, West Java Province were contaminated by *E. coli* [10]. Many food handlers do not perform proper hand-washing habit, only 48.3% of food handlers used soap to wash and rub their hands including washing fingers, fingertips and wrist [11]. There is 42.1% have not good quality of cookware and cutlery and 42.1% have not good food processing place [12].

Based on this condition, the objective of the study was to observe the individual characteristics of food handlers, the hygiene sanitation of food handlers at elementary school canteen, the quality of snacks with bacteria parameters (*Coliform* and *E. coli*) and to find out variables related to *E. coli* contamination on elementary school canteen's snacks.

Material and Method

Study design: This study used cross-sectional design carried out on December 2018 to April 2019. Analysis units were food handlers and canteen's snacks at elementary school in Pancoran Mas District, Depok City, Indonesia. The number of samples were calculated from the proportion estimated by Lemeshow formula with 90% CI, 10% precision and 0.33 proportion for *E. coli* contamination on elementary school snacks. Thus, final samples were 74 food handlers and snack samples taken using simple random sampling method.

Inclusion criteria for food handlers were permanent food handlers selling snacks at the school canteen and the sample snacks were the children's most favorite ones and the not-registered snacks. Besides, researcher interviewed respondents to gather information on training records of hygiene sanitation and food safety, hand-washing habit, food processing and preparation, quality of cookware and cutlery and sanitation of the location and the food-preparing place. Data about food quality were analysis from Environmental Health Laboratory, Faculty of Public Health, Universitas Indonesia although the researcher also counted the fly density by Scudder Method.

Collection of samples: The researcher had collected 74 snack samples. We had taken 30 gram or milligram and put them in sterile bag, then place it into cool box and transported it to the laboratory for analysis to avoid contamination[13].

Preparation and dilution of sample: This study used modification method from Bacterial Analytical Manual Chapter 4: Enumeration of *E. coli* and the *Coliform* bacteria and Regulation of National Standardization Agency of Indonesia Number 3554:2015 for analysis *Coliform* and *E. coli*. We did homogenate 10 gram or 10 ml of samples into 90 ml sterilized distillated water. Three-fold serial dilutions of homogenized samples were performed using sterilized distillated water as diluent. One milliliter of each dilution was inoculated into sterilized petri dish and pour the media. The content in the petri dish was swirled gently to mix sample with media. The plates were incubated at 35°C for 24 hours[13–15].

Enumeration for Coliform and E. coli: ChromoCult® Coliform Agar (Merck KGa A, Germany) was employed for enumeration of *E. coli*. The colonies of *E. coli* appeared purple or dark blue on petri dishes after incubation at 35°C for 24 hours [16].

Statistical analysis: We analyzed all of the data by using analysis software and described statistical measures, such as frequency, percentage, standard deviation and odds ratio after analysis logistic regression multivariable. Level of significance was $p > 0.1$ with 90% Confident Interval.

Findings: The respondents consisted of male (24.3%) and female (75.7%). The interview results showed many food handlers never attended training on hygiene sanitation and food safety (79.7%), poor food processing and preparation (67.6%), poor quality of location and food preparation place (83.4%), good quality of cookware and cutlery (50%) and many respondents performed hand-washing habit (67.6%), but many of them did not use gloves (91.9%) while handling

food. In months ago, some food handlers suffered from digestive tract disorder (20.3%) but it was related to *E. coli* contamination. Individual characteristics of food handlers are shown in Table 1.

Table 1. Individual characteristics of food handlers (n=74)

	n (%)

Coliform	
Negative	44(59.5)
Positive	30(40.5)
Escherichia coli	
Negative	67(90.5)
Positive	7(9.5)

Most samples were food with a high-risk contamination (40.5%) and some samples were contaminated by *E. coli* (8.1%) (Table 2). The high-risk food contain a high nutrient content and are not being served immediately after being cooked. This study also found that many snacks were contaminated with *Coliform* and *E. coli* used chicken in their presentation (Table 3).

After we analyzed all variables with *E. coli* contamination in snacks using logistic regression multivariate, we found that food with a high nutrient content and not being served immediately (high risk) had 21 times likelihood to get contaminated by *E. coli*, compared to food with a low nutrient content and being served immediately to students (p value= 0.024) after being controlled for the quality of food processing and preparation and hand-washing habit. The data is presented in Table 4.

Table 3. Contamination Bacteria in food sample (n=74)

Having hand-washing habit	6.251	0.818 – 47.762	0.138
Poor food processing and preparation	8.869	1.198 – 65.662	0.073*

*significant (p-value < 0.1), OR: Odds Ratio, CI: Confident Interval

Discussion

This study found that food with a high nutrient content and not being served immediately (high risk) were at risk for *E. coli* contamination (p=0.024). It is in line with literature which explains that bacteria need three important stuff to multiply itself, they are nutrients such as protein, moisture and warmth [7]; hence, temperature must be considered to keep food remain safe. Most bacteria do not like to be at cold or hot temperature, so that the range is in between the called "Danger Zone". Danger zone begins at 41°F and ends at below 135°F[7,8,17]. This is where bacteria can growth and multiply itself rapidly and cause any foodborne illness[2,7,8], then food must be served immediately if temperature is still hot or not kept in danger zone before serving them to customers.

In addition, there are other factors related to microbial contamination. They are unsafe sources, poor personal hygiene of food handler, improper cooking, unqualified holding temperatures and contaminated equipment [5]. This condition was called cross contamination.

Another microbial-related factor such as *E. coli* contamination is food preparation [5,6]. This study found that poor food processing and preparation had 8 times likelihood (p=0.073) of being contaminated by *E. coli*, compared to foods with good food processing and preparation.

Cooking foods, combining food served on the same plate and uncovered food for a long time can increase risk for microbial contamination [6]. Many preparation activities at kitchen such as cooking, washing, shredding, mixing and using several equipment that are common to both processing and preparation can be contaminated the food. Most of bacteria such as *E. coli* are destructed with a high temperature. Food must be cooked at 165°F, but some foods only need to be cooked to 155°F for at least 15 seconds as it is called cooking by adequate heating [7]. Step to prevent the entry of *E. coli* on food is by maintaining the hygiene of food handlers by washing hand after using bathroom and cooking food thoroughly (155-165°F) [6–8].

Food handlers also become a vehicle for spreading bacteria or microorganism directly by their hands [5,6,8,18]. In the United States, hygiene practices of food handlers are one of five most important risk factors for food poisoning and 89% of the illness outbreaks [5]. Hand-washing habit can reduce microbial contamination from the food handler's hands to the food they serve[5,8,19,20]. The principles for hand-washing depends on following considerations, that are using water power, having good length of time for washing (15 – 30 seconds), using soap, washing fingers, palms, back, wrists, nails and subungual region and rubbing fingers and palms during rinsing frequently and intensely [8,19]. However, there is a research explaining that only 48.3% food handlers used soap to wash their hands and rubbed hands including washing fingers, fingertips and wrist. They are also washing their hands in less than 10 seconds (41.4%) and the research highlights that the important stuff is that rubbing hands and increasing frequency of hand-washing can remove microbial load such as *E. coli* [19]. That theory supports this study because this study do not have significance result (p = 0.138) about hand-washing and *E. coli* contamination. When collecting data, the researcher only gave questions about hand-washing habit, but did not observe the food handlers' hand-washing practice, so that we did not know whether their habit was proper.

Conclusion

This study found that the foods not being served immediately (high risk) and the poor food processing and preparation increase the *E. coli* contamination on snacks sold at elementary school canteen.

The Effect of Development and Treatment Group Counselling on The Self-Concept of Delinquent Students

Nurul Fazzuan Khalid[1], Mohammad Nasir Bistamam[2], Nor Shafrin Ahmad[1]

[1]Universiti Sains Malaysia, Malaysia, [2]Universiti Pendidikan Sultan Idris, Malaysia

Abstract

This experimental study was conducted based on two main objectives. First, to measure the effect of Development and Treatment Group Counseling (KKPR) on self-concept between treatment groups and control groups. Second, to measure the impact of Development and Treatment Group Counseling (KKPR) on self-concept between marathon treatment groups, weekly treatment groups and control groups. A total of 60 subjects were divided into three groups consists of weekly treatment group, Marathon treatment group and control group. Pre-test and post-test data were collected through Multidimensional Self Concept Scale and analyzed descriptively and inferentially through statistical test of mean, MANCOVA and Post-Hoc Tukey at the significance level of 0.05. The results showed that first, was significantly effective in increasing self-concept of subjects in treatment group compared to the subjects in control group. Second, KKPR more effective on the weekly treatment group compared to the marathon treatment group. As a conclusion, KKPR is effective to improve self-concept among the subjects in treatment group. Overall, the outcomes of this study give a new perspective theoretically and practically in the field of counseling and psychology in order to address the delinquent behavior among students.

Keywords: *Group counseling, self-concept, treatment groups, control groups.*

Introduction

The process of identity and personality development can be fostered through a structured education system starting from the primary school to the highest education institution. According to Bakar[1], our current education system needs to be functional and community building oriented. In order to optimize the diversity of talent, capabilities, skills and interests among students, the Ministry of Education (MOE) has established several types of schools to meet these needs including National Religious Secondary School (SMKA). The diversity of secondary schools established has its own goals, rules and norms, but ultimately upholds the National Education Philosophy in order tohave a generation that is spiritually and physically balanced[2].

As a well-established educational institution, SMKA consists of students who came from early to middle adolescence stage and here, they have outlined and several key goals which are to educate students with Islamic beliefs, providing knowledge that meets the demands of the world and hereafter and develop students' potential in terms of interest, creativity, personality and leadership. SMKA is an important institution for empowering students to have a strong sense of identity, strong religious beliefs as well as being excel in academic, personal and disciplinary by not gettinginvolved in any delinquent behavior[1].

However, despite the planning and strategy set by the Ministry of Education (MOE), issues regarding to delinquent behavior among students has spread to students at SMKA. Moreover, this study involved a group of students at National Islamic Secondary School (SMKA) who are excel in academic and co-curricular, but some of them were involved in delinquent behavior. Students who had been selected to study in SMKA were chosen based on the excellent results obtained in the Primary School Evaluation Test (UPSR) for admission to Standard 1 and the Form 3 Assessment (PT3) for entry into Standard 4 in SMKA.

The differences and unique identities of SMKAs have always been respected by the community but on the other hand, the community is very sensitive to what

is happening to these students at SMKA[3]. Despite attending SMKA, it is possible that this delinquent and behavioral problem is still present as not the whole time the student is in the hostel especially during the school holidays[4].

Therefore, in this study a development and treatment group counselling (KKPR) module has been developed as an intervention treatment on psychological aspect which is self-concept by focusing on the process of development and treatment. The approach that being used for this study purpose is Rationale Emotive Behavior Therapy (REBT).

Literature Review: There are many factors that can lead to adolescent delinquency and one of the significant factors is self-concept[5]. Rosenberg [6] said that the self-concept has been conceptualized traditionally as containing both cognitive and affective components (totality of the individual's thoughts and feelings having reference to himself as an object of evaluation). Herson[7] defined self-concept as a self-belief, self-attitude and self-perception that one feels true about himself or herself.

Levey et al. [5] in their study found that adolescents who have low level of self-concept reported higher levels of delinquency and he suggested that future research need to examine the protective role of self-concept in preventing adolescent delinquent behavior. Research conducted by Kõiv[8] found that among juvenile delinquents analysis shows that there is negative significant correlation between self-concept and negative behavior (aggressiveness anger, contempt, disappointment, disgust, fear, remorse, sadness, submission). Finding from another study by Blakely-McClure et al. [9] revealed that having higher levels of self-concept lead todecreases in relational aggression across the transition toadolescence.

The above finding also parallel with the finding from the study by Gupta et al [10] as they found that there was significant positive relationship found between prosocialbehavior and self-concept of adolescents. Analysis through Hierarchical Linear Regression analyses suggested that the combination of low self-esteem (fragile self-concept) with high narcissism (grandiose self-view) may contribute to the continuation of both bullying and victimization[11].

Although the associations between self-concept and delinquent behavior have not much been directly examined by the past research, research on identity development and adjustment suggests that questioning and rethinking one's sense of self is associated with higher delinquency[5]. Higher reconsideration of identity commitments has been related to higher delinquency[12] and more externalizing problems[13]. Besides, self-concept is also related to several indices of psychosocial functioning, such as anxiety and depression[14-16]. In a study conducted by Hehsan et al.[17] at one SMKA in Kelantan, they found there were five significant factors contribute to students' delinquency which were environment, self-awareness, family, teachers and school.

Research Objective: There are two main objectives in this study that listed as below:

i) To measure the effect of Development and Treatment Group Counseling (KKPR) on self-concept between treatment groups and control groups.

ii) To measure the impact of Development and Treatment Group Counseling (KKPR) on self-concept between marathon treatment groups, weekly treatment groups and control groups.

Methodology

This study involved 60 male students who had low level of self-concept at one National Islamic Secondary School in Perak, Malaysia. In order to measure their self-concept, they need to filled up a questionnaire known as Multidimensional Self-Concept Scale (MSCS) [18] before being choose as subject in the experimental study.

Subjects in this quasi-experimental study were divided into two major groups which were treatment (R) and control groups (K) by using pair random sampling method. For treatment group, this group consists of two groups which were marathon treatment group (R1) and weekly treatment group (R2). Subjects participated in the treatment session through Development and Treatment Group Counselling (KKPR) that adapted from a Development and Treatment Group Counselling (KKPR) on self-concept by Mohammad Nasir [19].

Findings:

Descriptive analysis to see KKPR's impact on the self-concept for treatment and control group: Table 1 shows the results that has been analyzedto see the difference between the pre-test and post-test mean score between treatment (R1 and R2) and control (K) group.

Overall, KKPR module able to improve the self-concept of subjects in both treatment groups, R2 (+20.25) followed by R1 (+.8.4). However, the mean score for control group has reduced by -1.75. As the conclusion, KKPR module successfully increase the self-concept of subjects in treatment group and more effective on weekly treatment group compare to marathon treatment group.

Table 1: A summary of descriptive analysis of pre-test and post-test on self-concept of the treatment and control group

Variable	Groups	Mean		
		Pre-test	Post-test	Difference Between Pre and Post Test
Self-Concept	R1	61.25	69.65	8.40
	R2	59.60	79.85	20.25
	K	60.65	58.90	- 1.75

*Note: R1 (marathon treatment group); R2 (weekly treatment group); K (control group)

MANCOVA analysis to see KKPR's impact on the self-concept for treatment and control group: A multivariate analysis of covariance (MANCOVA) was conducted to compare the effectiveness of KKPR to improve subjects' self-concept between marathon treatment group (R1), weekly treatment group (R2) and control group (K). According to Table 2, it shows that there was a significant difference of the mean scores, $F = 113.27$ ($p = .00$). The result also demonstrates that there is a significant difference of the mean scores for separate groups ($p = .00$). Analysis also revealed that there is a significant difference in the measurement of pre-test and post-test on self-concept between the treatment group and the control group.

Table 2: MANCOVA analysis on the effect of KKPR on mean scores of pre-test and post-test on self-concept (SC) among the subjects

Sources	Control Variables	df	Mean Square	F	Sig.
SC pre-test	SC post-test	1	3274.11	113.27	.00
Groups	SC post-test	2	2123.90	73.48	.00

*p< .05

As there is a significance difference between groups, therefore a Post-hoc Tukey analysis has to be conducted to identify the effect of KKPRon the different group types (R1, R2 and K). Table 3 shows that there is a significant difference of self-concept between R1 and R2 ($p = .01$), between the R1 and K ($p = .01$) and between R2 and K ($p = .00$) on self-concept as a whole. KKPR is more effective to improve self-concept level among subjects in weekly treatment group compare to marathon treatment group.

Table 3: A summary of Post-Hoc Tukey Analysis on min score difference between marathon treatment groups, weekly treatment groups and control groups on self-concept (SC) among the study samples.

Variable	Types of Groups		Mean Difference (I – J)	Sig.
	I	J		
SC	R1	R2	- 10.20	.01
	R1	K	10.75	.01
	R2	K	20.95	.00

*p< .05, *Note: R1 (marathon treatment group); R2 (weekly treatment group); K (control group)

Discussion

The KKPR module that being used in this study was a developmental and treatment-based intervention. This structural module was developed according to counselling approach, Rationale Emotive Behavior Therapy (REBT). The result of the study shows that KKPR is effective in providing a developmental and treatment intervention on self-concept among National Islamic Secondary School (SMKA) students who are delinquent whereas the effectiveness of this module has been proved through the analysis that had been conducted. Results revealed that there is a significant different of the mean score for pre-test and post-test between the self-concept of subject from the treatment and control group.

In reality, it is important for every party to cooperate and working together to identify the factors that lead adolescents getting involve in delinquent behavior at early stage. By understanding the characteristic of adolescents who are involving in delinquent behavior, it can lead to the next stage which is by conducting an intervention step to prevent them from getting involve in more serious crime behavior in future[20]. The development and treatment intervention emphasis on the process to improve the individual developmental aspects by identified and change the current delinquent behavior that lead them to involve in various problematic behavior, to a more positive behavior especially when they face a stressful situation.

In Malaysia, many studies [21-23] suggested that issues related to delinquent behavior among students or adolescents need to be solved through early treatment and suitable intervention program such as counselling or psycho educational cognitive program to constrain these issues from become more severe in the future.

Conclusion

This development and treatment study have been carried out on a group of delinquent National Islamic Secondary School (SMKA) students as an enforcement to the existing program, specifically to overcome students' delinquent behavior. Implementation of the KKPR intervention in this study was able to improve the psychological aspects of students who are delinquent. The psychological aspect includes various aspects which are thinking, feeling and behavior was assessed through the self-concept score. Emphasis on this psychological aspect is not a straightforward solution to delinquent behavior, but it does play a role in improving the internal aspects that are the main factors to the involvement in delinquent behavior. By treating the cause of the problems at the early stage, this group of students can control their behavior from involving in delinquent behavior.

Relationship between Screen Time Towards Physical Activity, Sleep Disorders, Prosocial Behavior and Emotions of Children 4-6 Years

Oktaviany Ismiarika Sulistyanti[1], Sri Widati[2], Irwanto[3]

[1]Student Master of Public Health, [2]Departement of Health Promotion, Public Health Faculty, [3]Department of Child Health, Faculty of Medicine, Airlangga University Surabaya, Indonesia-60131

Abstract

The current use of screen media in preschoolers exceeds the recommended level. Parents have a major role in growth and development and provide the most influence on the behavior of their children. This study aims to determine the relationship between screen time to physical activity, sleep disturbance, prosocial behavior and emotions of children aged 4-6 years.

The research method is a cross sectional study with primary data through interviews using a standardized questionnaire to parents (n=397) for assess screen time, physical activity, sleep disturbance, prosocial behavior and emotions.

The results showed a significant relationship between screen time with physical activity (*P=0,000)*, sleep disturbance (*P=0,000)*, prosocial behavior (*P=0,*047) and emotions (*P=*0,004) of children aged 4-6 years. The higher duration increases the risk of less physical activity, sleep disturbance, borderline status and abnormal for prosocial and emotional behavior.

Conclusion: there is a significant relationship between screen time with physical activity, sleep disturbance, prosocial behavior and emotions of children aged 4-6 years. The duration of use of screen media in children should be <1 hour/day to reduce the negative effects that can be caused.

Keywords: *Screen time, Physical Activity, Sleep Disorders, Prosocial Behavior and Emotions.*

Introduction

In the digital era, various types of communication media are increasing rapidly and their use is increasingly widespread in everyday life in preschoolers in the world. Preschool age is a critical period in the development of health behaviors such as regular physical activity and minimal sedentary behavior. Sedentary behavior in children of this age is the time of exposure which includes the use of television, DVD/video, computers, electronic games and portable smart media devices. Recent studies have found that sedentary behavior using screen media has a detrimental effect on health on a variety of physical, cognitive and psychosocial indicators. The longer duration of use of screen media can affect the status of body weight, blood pressure, bone mineral content, social development and increased behavior problems.(1)

Based on the results of research conducted by The Asian Parent Insights in November 2014 as many as 98 percent of 2,714 parents in Southeast Asia who took part in this study allowed their children to access technology in the form of computers, smartphones or table ts. This study was conducted on 2,714 parents in Southeast Asia who have children aged 3-8 years. The parents of the study participants came from Singapore, Malaysia,

Corresponding Author:

Student Master of Public Health at Airlangga University Surabaya, Indonesia, 60115
e-mail: oktavianyismiarika@gmail.com

Thailand, Indonesia and the Philippines. From the survey results, most parents allow their children to play gadgets for educational purposes. But in reality according to the survey results most of their children use these gadgets/ table ts for entertainment purposes such as games.[2]

Nowadays the time spent by children to use screen media every day is more. The time spent watching television is on average 3 hours on weekdays and 7.4 hours on holidays, the time playing electronic games is 3.8 hours and the time spent on internet playing is an average of 2.1 hours. Data from Nielsen Media shows that one out of every four television viewers in Indonesia is a child and the time spent by children watching television is an average of three hours/day.[3]

Current conditions, the use of screen media in the majority of preschool children still exceeds the recommended level so it is important to identify factors associated with behavior while using preschool children screen media to inform the development of behavior reduction strategies. Parents have a major role in growth and development and provide the most influence on the behavior of their preschool children.[4] This study aims to determine the relationship of screen time with physical activity, sleep disorders, prosocial behavior and emotions of children aged 4-6 years.

Method

This cross sectional study was conducted to determine the relationship between screen time with physical activity, sleep disturbance, prosocial behavior and emotions of children aged 4-6 years.

This research was conducted at several kindergarten institutions in Tambaksari District, Surabaya City. Tambaksari Subdistrict, Surabaya City was chosen because it has the largest Kindergarten institutions in all of Surabaya, with 96 institutions. the number of 5197 students from 96 institutions.

In this study the sample is parents of students who are members of kindergarten institutions in Tambaksari Subdistrict, Surabaya who meet the criteria of children having 4-6 years of age, have been exposed to screen media in the past 1 year and are not children with congenital abnormalities, paralysis, blindness, deafness and special needs. The sampling technique used in this study is probability sampling type of simple random sampling. Based on the sample calculation a minimum sample of 397 students was obtained. In this study the independent variables are screen time and dependent variable is physical activity, sleep disturbance, prosocial behavior and emotions.

Data collection techniques in this study were Early Year Physical Activity Questionnaire (EY PAQ) to assess pre-school children's activities. Children Sleep Habit Questionnaire (CSHQ) is used to assess sleep disorders. Strength and Difficulty Questionnaire (SDQ) to assess the status of a child's prosocial and emotional behavior.

Data analysis used nonparametic statistical test namely chi-square to find out whether there was a relationship between the two variables studied. Significance test is done by comparing the significance value obtained with α, if $p < \alpha$ ($\alpha = 0.05$) there is a significant relationship.

Results

Table 1 showed a tendency for the higher duration of screen time were increase the number of children with less physical activity. Nearly half the children who use screen media 1-2 hours/day have less physical activity and are increasing in number with children who use screen media> 2 hours/day. Statistical test results show a significant relationship between screen time with physical activity of children aged 4-6 years.

Table 1. Relationship between Screen time with Physical Activity

Screen time	Physical Activity				Total (n = 397)		P value
	Enough		Less				
	N	%	n	%	n	%	
<1 hour/day	61	79.2	16	20.8	77	100	0,000
1-2 hours/day	101	53.2	89	46.8	190	100	
> 2 hours/day	35	26.9	95	73.1	130	100	
Total	**197**	**49.6**	**200**	**50.4**	**397**	**100**	

Table 2. Relationship between Screen time with Sleep Disorders

Screen time	Sleep Disorders				Total (n = 397)		P value
	Sleep Disorders		Normal				
	N	%	n	%	n	%	
<1 hour/day	54	70.1	23	29.9	77	100	0,000
1-2 hours/day	164	86.3	26	13.7	190	100	
> 2 hours/day	124	95.4	6	4,6	130	100	
Total	342	86.1	55	13.9	397	100	

Table 2 showed the higher duration of screen time has a tendency to increase sleep disorders in children. Almost all children with sleep disorders have a duration of screen use behavior > 2 hours/day. Statistical test results show a significant relationship between screen time with sleep disorders in children aged 4-6 years.

Table 3. Relationship between Screen time with Prosocial Behavior

Screen time	Prosocial Behavior						Total		P value
	Normal		Borderline		Abnormal				
	n	%	n	%	n	%	n	%	
<1 hour/day	70	90.9	2	2.6	5	6.5	77	100	0.047
1-2 hours/day	170	89.5	11	5.8	9	4.7	190	100	
> 2 hours/day	103	79.2	14	10.8	13	10	130	100	
Total	343	86.4	27	6.8	27	6.8	397	100	

Based on table 3 shows the higher duration of screen time increasingly increases the number of prosocial behavior with borderline and abnormal statuses. This is supported by the results of statistical tests that show a significant relationship between screen time with prosocial behavior of children aged 4-6 years. The higher duration of use of screen media results in prosocial behavior becoming borderline and abnormal.

Table 4. Relationship between Screen time with Emotional Behavior

Screen time	Emotional Behavior						Total		P value
	Normal		Borderline		Abnormal				
	n	%	n	%	n	%	n	%	
<1 hour/day	72	93.5	3	3,9	2	2.6	77	100	0.004
1-2 hours/day	175	92.1	12	6.3	3	1.6	190	100	
> 2 hours/day	103	79.2	20	15.4	7	5,4	130	100	
Total	**350**	**88.2**	**35**	**8.8**	**12**	**3**	**397**	**100**	

Based on table 4 shows the higher duration of use of screen media increasingly increases the amount of emotional behavior with borderline and abnormal statuses. Statistical test results show a significant relationship between screen time with emotional behavior of children aged 4-6 years.

Discussion

Relationship between Screen time with Physical Activity: Physical activity is defined as any body movement produced by skeletal muscles and results in a significant increase in resting energy expenditure. Physical activity can also be defined as a physical movement that causes muscle contraction.[5]

In line with previous research that the more time children spend in front of the screen, the less they spend in physical activity. The physical activity of children who do not use the game increases 3.8 minutes per day. Children who spend a lot of time playing video games can also spend sufficient time in physical activity and children who do not play video games can also refrain from physical activity if their activity preferences settle

(for example, reading, music art). Modification of the type of game by providing active input is not effective to maintain an increase in physical activity over time.[5,6]

Thus parents should reduce the duration of use of screen media in children <1 hour/day, do not provide screen media facilities in a child's bedroom and provide policies to limit the use of screen media in children.

Relationship between Screen time with Sleep Disorders: The results of this study are in accordance with previous studies the use of television in a child's bedroom can ruin healthy sleep. Light Emitting Diodes (LEDs) are found in most screen media used by children.[7] The light emitted by LEDs contains more blue wavelength light than ordinary incandescent light bulbs. Blue wavelength light is found naturally in the morning and is important for regulating the circadian system. This type of light stimulates the suprachiasmatic nucleus to suppress the production of melatonin a hormone that encourages sleep. Thus, blue light waves at night can disturb sleep. Prolonged contact with screen media before going to sleep is associated with poor sleep patterns.[8]

Relationship between Screen time with Prosocial Behavior and Emotions: In line with other study that showed higher duration screen time is associated with problems with prosocial behavior and emotional behavior of children. Parents of socioeconomic status, different education allows their children to engage with digital media and many believe that it can enhance children's creativity and academics.[9] The duration of screen time which is higher can affect the behavior and emotions of children. A number of studies have concluded that the addictive behavior of screen media results in changes in the structure of the frontal lobes of the brain. These structural changes are related to the ability to filter out irrelevant information and not deal with complex task demands. Frontal lobes are also associated with empathy, difficult to adapt to the environment.[10] Another longitudinal study of a 2-year-old child states that only one hour of daily TV exposure is associated with expressions of aggression, social difficulties and increased violence in peers at the age of 13 years.[11]

Other studies found that media content influences children's behavior and emotions. With more exposure to children's film behavior and emotions better than exposure to children's TV programs. This can happen because the film provides more opportunities for discussion and mental management than television, while watching television children are often solitary activities.[12]

The game media content is much in the lives of children so there is great potential to improve children's performance in many fields, including the development of social emotions. Other research showed that almost all the games in the research sample give children the opportunity to learn social-emotional skills from a level of basic complexity (exploration level); half of the games have higher assignments, develop and build complexity levels, but only one fifth of the games allow children to pass to the most challenging tasks of integrating online game complexity levels for preschoolers thus providing little opportunity to improve in many tasks and mastering social-emotional. Many educational games that make children trapped at the same level of complexity and do not increase challenges so that it can cause children to lose interest in learning social-emotional skills through games.[13]

Conclusion

There are significant relationship between screen time with physical activity, sleep disturbance, prosocial behavior and emotions of children aged 4-6 years. The higher duration of screen time can reduce the risk of having physical activity, experiencing sleep disturbances, problems with prosocial behavior and children's emotions.

Suggestion: Parents need to monitor and limit the screen time in children 1 hour/day with age-appropriate recommendations.

Acknowledgements: On this occasion the author would like to thank the respondents who honestly filled out the questionnaire that had been given.

Conflict of Interest: The author states that there is no conflict of interest regarding the publication of this article.

Abstract

Objective: Evaluation of the antitrypanosmal, antileishmanial, antimicrobial and antimalarial activities of the total ethanol extract and different fractions of *Bignonia binata* leaves.

Method: The antitrypanosomal activity was evaluated *in vitro* on blood stage forms of *Trypanosomabrucei*and the antileishmanial activity was tested against *Leishmaniadonovani*. The antimicrobialeffect was performed against *Candida albicans* ATCC 90028, *Cryptococcus neoformans* ATCC 90113 and *Aspergillusfumigatus* ATCC 90906,*Staphylococcus aureus* ATCC 43300 (MRS), *Escherichia coli* ATCC 35218, *Pseudomonas aeruginosa* ATCC 27853 and *Mycobacterium intracellulare* ATCC 23068. While, the antimalarial activity was examined onchloroquine-sensitive (D6, Sierra Leone) and the chloroquine-resistant (W_2) strains of *Plasmodium falciparum* protozoan.

Results: The ethyl acetate fraction exhibited 90% inhibition against *Trypanosomabrucei*, with IC_{50} value of 16.59 µg/mL. While,the aqueous fraction showed mild antimicrobial activity with inhibition 32% aginst *Pseudomonas aerogenosa* and 27% against methicillin resistance *Staphylococcus aureus* (MRS). On the other hand, all tested fractions showed no antimalarial activity at the tested concentration.

Conclusion: The present study revealed the antitrypanosomal potency of *B. binata* leaves

Keywords: *Bignoniaceae, B.binata, antitrypanosomal, antileishmanial,antimicrobial, antimalarial.*

Introduction

Bignoniaceae is a flowering plants family, comprising of about 110 genera and 650 speciese and commonly known as the Trumpet Creeper family, Jacaranda family, Bignonia family, or the Catalpa family[1,2]. Bignoniaceaespecies are distributed over the world, but most of them occur in the tropical and sub-tropical countries. However, a number of temperate species grow in North America and East Asia. Additionally, they are reported to have bioactive secondary metabolites and diverse pharmacological activities. They are widely used in traditional medicinal systems of a number of countries for treatment of ailments like cancer, snake bite, skin disorders, gastrointestinal disorders, respiratory tract disorders, hepatic disorders, epilepsy, cholera, pain, urinary problems, malaria, heart problems, and sexually transmitted diseases[1]. Although, Bignoniaceae are a relatively large family, only a limited number of species has been studied chemically[3].

Bignonia L. is the fifth largest genus in the tribe *Bignonieae (Bignoniaceae*), with 31 lianas species distributed from Argentina to USA [4, 5].Most species are used in folk medicine for treating a wide range of ailments as skin ailments like fungal infections, boils,

e-mail: mamdouhnabil.2006@yahoo.com

psoriasis and eczema, dysentery, ringworm, tapeworm, malaria, diabetes and pneumonia, treat venereal diseases and treat ulcer[6,7]. *B. binata* Thunb. (syn: *Clytostomabinatum* Thunb.) is a liana and distributed from Mexico to Argentina[4]. There are no previous reports about *B. binata*, encouraged us to evaluate the antitrypanosmal, antileishmanial, antimicrobial and antimalarial activities of the total ethanol extract and different fractions of *B. binata* leaves

Materials and Method

Plant Material: The leaves of *B. binata* were collected in December 2015, from El-Zohria botanical garden, Giza, Egypt. Authentication of the plant was identified by Prof. Dr. Nasser Barakat, Professor of Botany, Faculty of Science, Minia University. A voucher specimen (Mn-ph-Cog-033) has been depoted in the Herbarium of Pharmacognosy Department, Faculty of Pharmacy, Minia University, Minia, Egypt.

Extraction and fractionation: The air dried, powdered leaves (2.7 kg) of *B. binata* were extracted by maceration with 95% ethanol and concentrated under reduced pressure to give solvent-free residue (420 g), which was then suspended in 400 ml of distilled water, and defatted with pet. ether, followed by partitioning with EtOAc (300 ml each x 6) and then the solvents were separately evaporated under vacuum, affording pet. ether (75 g) and EtOAc fractions (125 g). Finally, the remaining mother liquor was concentrated under reduced pressure to afford aqueous fraction (200 g).

Evaluation of antitrypanosomal activity: Blood stage forms of *Trypanosomabrucei* were grown in IMDM medium supplemented with 10 % fetal bovine serum. The assays were set up in clear 96 well microplates. A two days old culture of *T. brucei* in the exponential phase was diluted with IMDM to 5000 parasites/mL.The examined samples were tested at final concentration of 20 mg/mL. Each well received 4 ml of diluted sample (1 mg/mL) and 196 ml of the culture volume (total culture volume 200 ml). The plates were incubated at 37 °C in 5% CO_2 for 48 h. Alamar blue (10 mL) (ABD Serotec, catalog number BUF012B) was added to each well and the plates were further incubated overnight.

Standard fluorescence was measured on a Fluostar Galaxy fluorometer (BMG LabTechnologies) at 544 nm excitation, 590 nm emission. α-difluoromethyl ornithine (DFMO) was tested as standard. IC_{50} values were computed from dose-response curves[8].

Evaluation of antileishmanial activity: The antileishmanial activity of the investigated samples was tested against *Leishmaniadonovani,* a fly-borne protozoan, the main cause of visceral leishmaniasis. The promastigotes were grown in RPMI 1640 medium supplemented with 10% fetal calf serum (GibcoChem. Co.)at 26 °C. A three-day-old culture was diluted to $5x10^5$ promastigotes/ml. Dilution of the investigated samples were prepared directly in cell suspension in 96-well plates then incubated at 26°C for 48 h and the growth of *Leishmania* promastigotes was detected by the Alamar B1ue™ assay. Standard fluorescence was measured on a Fluostar Galaxy plate reader (BMG Lab Technologies) at a wavelength excitation 544 nm and an emission wavelength of 590 nm. Amphotericin B was used as standard antileishmanial agents. IC_{50} values were computed from dose-response curves[9].

Evaluation of antimicrobial activity: The biological evaluation of the Total ethanolic extract and different fractions was performed against different organisms obtained from the American Type Culture Collection (Manassas, VA) and included the following fungi, *Candida albicans* ATCC 90028, *Cryptococcus neoformans* ATCC 90113 and *Aspergillusfumigatus* ATCC 90906 and the followirig bacteria, *Staphylococcus aureus* ATCC 43300 (MRS), *Escherichia coli* ATCC 35218, *Pseudomonas aeruginosa* ATCC 27853 and *Mycobacterium intracellulare* ATCC 23068. Susceptibility testing was performed using a modified version of the CLSI method. The investigated samples were serially diluted in 20% DMSO/saline and transferred in duplicate to 96-well flat-bottom microplates.

Microbial inocula were prepared by correcting the OD630 of microbe suspensions in incubation broth to afford final target inocula. Amphotericin B (ICN Biomedicals, Ohio) for fungi and ciprofloxacin (ICN Biomedicals, Ohio) for bacteria are provided as positive controls in each assay. All organisms were read at either 630 nm using the EL-340 Biokinetics Reader (Bio-Tek Instruments, Vermont) or 544ex590em (*M.* intracellulare and *A.* fumigatus) using the Polarstar Galaxy plate reader (BMG LabTechnologies, Germany) prior to and after incubation. Percentage growth was plotted versus test concentration to afford the IC_{50}[10].

Evaluation of antimalarial activity: According to Makler and Hinrichs, 1993 the TEEs and different fractions were evaluated for *in vitro* antimalarial and inhibition properties to the chloroquine-sensitive

(D6, Sierra Leone) and the chloroquine-resistant (W_2) strains of *Plasmodium falciparum* protozoan. The tested samples were screened against a suspension of red blood cells infected with *P. falciparum.* Two hundred µl, with 2% parasitemia and 2% hematocrit in RPMI-1640 medium supplemented with 10% human serum and 60 µg/ml amikacin was added to the wells of a 96-well plate containing 10 µl of test samples at 15.867 µg/ml in duplicates and the percentage of inhibition was calculated relative to the negative and positive controls. The sample that showed % inhibition ≥ 50% were further proceeded to the second phase assay. In the second phase assay, the tested samples examined at 47.6, 15.867 and 5.289 µg/ml and the tested concentrations that afforded 50% inhibition of the protozoan relative to positive and negative controls (IC_{50}) against the chloroquine-sensitive (D6) and the chloroquine-resistant (W2) strains were reported. Concurrently, all samples were tested against the VERO mammalian cell lines as an indicator of general cytotoxicity.

The selectivity indices (SI) and ratio of VERO IC_{50} to (D6 or W2) were calculated. The standard antimalarial drug chloroquine(79 ng/ml) was used as the positive control while DMSO 0.25% was used as a vehicle. All IC_{50} are calculated using the XLSit curve[11].

Results and Discussion

Many of Bignoniaceae plants had been reported to have antitrypanosomal activity [12]. Likewise, our results of the biological screening of *B. binata* leaves total ethanol extract and fractions revealed the potent activity of the ethyl acetate fraction against *T. brucei*. Whereas, it was the most active one, exhibited 90% inhibition against *T. brucei*, with IC_{50} value of 16.59 µg/mL (Table 1). Likewise, the aqueous fraction showed mild antimicrobial activity in which, it exhibited percentage of inhibition 32% aginst *P. aerogenosa* and 27% against MRS. While, the other fractions exhibited weak or no antimicrobial activity (Table 2). On the other hand, all tested fractions showed weak or no antileishmanialactivity against *L. donovani*at concentration 20 µg/mL in primary phase (Table 1). Additionally, the tested samples showed no activity at concentration 15.87 µg/ml against *P. falciparum.*

Table 1: The antileishmanial and antitrypanosomal activities of the total ethanolic extract and different fractions of *B. binata*.

Strains / Tested drugs	Inhibition Percentage (%)			
	L. donovani-Pinh	*L. donovani* AMAST-Pinh	*L. donovani* AMASTTHP-Pinh	*T. brucei*_Pinh
Amphotericin B	100	96	97	-
α-Difluoromethyl ornithine	-	-	-	100
Total ethanolic extract	3	0	0	3
Petroleum ether fraction	5	0	12	2
Ethyl acetate fraction	2	0	13	90
Aqueous fraction	0	1	16	1

All (20 µg/ml) except Amphotericin B (2 µg /m1).

Table 2: Antimicrobial activity of *B.binata* leaves.

Strains / Tested drugs	Inhibition Percentage (%)							
	C. albicans	A. fumigatus	C. neoformans	MRS	E. coli	P. aerogenosa	K. pneumonia	VRE
Total ethanolic extract	0	7	21	0	18	5	0	6
Petroleum ether fraction	0	2	7	0	18	0	0	3
Ethyl acetate fraction	0	5	16	0	0	2	0	7
Aqueous fraction	0	9	0	27	4	32	8	10

Conclusion

The findings of the present study revealed the potent antitrypanosomal activity of the ethyl acetate fraction against *T. brucei* and the mild antimicrobial of the aqueous fraction. On the other hand the other fractions exhibited weak or no activity on the tested concentration.

Attitude to Conserve Mangroves and Coral Reefs in Environmental Education: Survey and Analysis in Community

Diana Vivanti Sigit[1,2], Mieke Miarsyah[1,2], Ratna Komala[1,2], Ade Suryanda[2], Ilmi Zajuli Ichsan[1]

[1]Master Program of Biology Education, [2]Program Study of Biology Education, Faculty of Mathematics and Natural Science, Universitas Negeri Jakarta, Indonesia

Abstract

The destruction of coral reefs and mangroves is an urgent problem to be solved together. The purpose of this study was to describe profile of community attitudes in conserve coral reefs and mangroves. The research method used was descriptive method with survey techniques. The study was conducted on July 2019. This research used 214 samples were selected by simple random sampling, which is a community that lives in the city of Jakarta, Bogor, Depok, Tangerang, and Bekasi (*Jabodetabek*) and other cities. The instrument used 18 items that measure attitudes. The results showed that the attitude score of the community was 82.40 which is categorized very high. In addition, other findings were that most respondents were from the age range of 16-20 and 21-25 years. High attitude score has not yet determined that their behavior also have a high score. Various efforts to improve indicators that are still low such as regarding community participation in seminars on coral reefs and mangroves that can be done with the Environmental Education Community Network (EECN). The conclusion was that the attitude of the community was already in the very high category, but further efforts need to be made to improve that attitude through environmental education.

Keywords: *Attitude, community, environmental education, profile.*

Introduction

Pollution in big cities has been a discussion of a various researcher in recent years. Starting from air pollution caused by motor vehicle to factory activities[1–3]. In addition, pollution also occurs water in big cities. Many rivers have pollution so the water is not suitable for consumption. However, no less important is the destruction of coral reefs and mangroves on the coast[4–6]. The damage to mangroves and coral reefs makes it necessary for efforts from the community to overcome them. Damage to coral reefs and mangroves caused by several parties who are not responsible.

e-mail: dianav@unj.ac.id

People who live in big cities cannot stay silent with the damage to mangroves and coral reefs that occur. They must participate in overcoming these environmental problems. Problem-solving these environmental problems need an attitude and awareness of the community in protecting the environment [7,8]. All components of society must participate, both among students, housewives, traders, employees, and others. Start from people who are young to old, must take part in protecting the environment, for this reason community attitudes are needed in protecting the environment especially about coral reef and mangroves. The attitude of the community in protecting the environment can be defined as a person's tendency to act in protecting the environment[9,10]. Attitudes are different from the behavior when someone who has a good attitude is not necessarily directly proportional to his behavior[11,12]. This attitude must be instilled in the community in big cities through environmental education. The problem is that many studies have not been able to reveal how much the community's attitude in protecting coral reefs and mangroves.

The research that has been done has a lot to discuss students' attitude profiles[13,14]. In addition, many are also researching about what factors affect a person's attitude[8,15,16]. All of these studies usually only describe one or only community groups. Especially the problem of damage to coral reefs and mangroves, many aspects that have not been seen both in terms of age and city of residence. This research becomes urgent because it is to overcome the damage of coral reefs and mangroves and prevent the damage becoming more widespread. Based on this, the purpose of this study was to describe the profile of community attitudes in big cities to conserve mangroves and coral reefs.

Method

This research was conducted on July 2019. The research method used was a descriptive method. The selected sample was from various regions in Jakarta, Bogor, Depok, Tangerang, Bekasi (*Jabodetabek*) and other cities. Samples were randomly selected, 214 respondent were selected as samples. The instrument used in the form of a questionnaire amounted to 18 items. The instrument was given to the community through Google Form. The indicator of instrument can be seen in Table 1 below.

Table 1. Indicator of instrument

No.	Indicator	Item
1	Support extension services and seminars on mangroves	1,2,3,11,12
2	Encourage the role of the community in protecting mangroves	4,5,6,16
3	Stop using coral reefs as building and decorative materials	7,8,9,10,13
4	Support community participation in coral reef conservation	14, 15,17,18

After the community fills in the attitude instrument then the attitude category will be seen according to the criteria that have been made. The interpretation, if a score> 81.28 can be interpreted that the categorical attitude is very high. Meanwhile, if the attitude score ≤ 38.72 can be said to be very low. More can be seen in table 2.

Table 2. Category of community attitudes

Category	Interval Score
Very High	$X > 81.28$
High	$70.64 < X \leq 81.28$
Moderate	$49.36 < X \leq 70.64$
Low	$38.72 < X \leq 49.36$
Very Low	$X \leq 38.72$

Findings and Discussion

The results showed that the average score was 82.40, which means the category was very high. Then more detailed descriptive data can be seen in table 3. Note for item with negative statements, the higher score means more contrary to the statement. It appears that the highest score is in item 14, which is about supporting conservation efforts by the conservation center. While the lowest is in item 9, which is the habit of using coral reefs as decoration.

Table 3. Average attitude score of the community in each item

No	Item	Average Score
1	Following seminars on mangroves will increase knowledge about mangrove conservation	4.47
2	I do not like to take counseling about mangrove conservation because it is a boring thing*	3.85
3	I am willing to supply information to the community about coral reef conservation.	3.74
4	The community must take part in fighting for the implementation of mangrove conservation	4.54
5	I like the people who carry out coral reef conservation activities	4.59
6	I will take part in activities related to mangrove conservation	3.86
7	I like to collect home displays made from coral reefs*	3.50
8	Coral reefs can continue to be used as building materials even though the population is declining*	4.18
9	Coral reefs are very beautiful if used as decoration*	3.21
10	Destruction of coral reefs will not disturb the balance of the ecosystem*	4.40
11	I will not care about the latest issues about mangrove*	4.05

No	Item	Average Score
12	I like to see mangroves being used as tourist attractions	3.67
13	If there is an opportunity, I will break the coral reefs in the sea to collect*	4.64
14	I am happy if the conservation center really strives for the conservation of mangroves and coral reefs	4.68
15	Coral reefs will be abundant if there is development in the coastal area*	4.02
16	The destruction of mangrove areas on a large scale will have an impact on the imbalance of the coastal ecosystem	4.50
17	I feel satisfied if something damages the coral reefs is punished legally	4.20
18	I will report to the authorities if there are tourists who damage the coral reef	4.03
	Average score	4.12
	Average score (0-100)	82.40

Note: *Item with negative statements, the higher score means more contrary to the statement.

After a detailed breakdown, a review of each indicator is then carried out. It is clearly seen that the indicator with the highest score is the second indicator which is encouraging the role of community in protecting mangroves. While the lowest item is seen in indicator 1, namely support extension services and seminars on mangroves. More details can be seen in table 4.

Table 4. Average attitude score based on indicators

No	Indicator	Score
1	Support extension services and seminars on mangroves	3.96
2	Encourage the role of the community in protecting mangroves	4.37
3	Stop using coral reefs as building and decorative materials	3.98
4	Support community participation in coral reef conservation	4.23

Meanwhile, when filling in the instrument respondents were asked to complete data on their age and city of residence. Most of the respondents came from the age group of 16-20 and 21-25 years. While there is only one respondent who is over 60 years old. More details can be seen in table 5.

Table 5. Distribution of respondents by age

Age interval (year)	Total respondent
10 - 15	23
16 - 20	67
21 - 25	67
26 - 30	17
31 - 35	12
36 - 40	10
41 - 45	3
46 - 50	6
51 - 55	8
>60	1

After that, when viewed from the respondent's residence, the highest number of respondents living in Bekasi. While those who live in Pandeglang at least. This city of residence showed that respondents living in various cities so that the results were more representative. More details can be seen in table 6.

Table 6. Distribution of respondents by residence

City of residence	Total respondent
Bekasi	57
Bogor	23
Depok	18
West Jakarta	23
Center Jakarta	5
South Jakarta	12
East Jakarta	25
North Jakarta	20
Tangerang	9
South Tangerang	4
Serang	5
Pandeglang	2
Another city	11

The results showed that the attitude of the community was very high. However, there are several important points (1) high score of attitudes may not necessarily have a high score of behavior (2) there is

still low score on the use of coral reefs (3) indicators of habits following the seminar are still low. The first point is that high attitudes do not necessarily determine high behavior. It can be seen that in big cities there is still a lot of pollution and pollution that occurs. Starting from the pollution of air, water, and soil. This is due to many people who have high score of attitudes but low score of behavior[17,18]. Likewise in the context of the preservation of coral reefs and mangroves.

The second point is the frequent use of coral reefs as decoration. This is very dangerous considering that if a coral reef is continuously taken it will cause damage to coral reefs. Then, coral reef extinction will occur later. Environmental organizations must do a lot of education for the community to stop taking coral reefs[19–21]. In addition, strict rules must be made for those who damage coral reefs. If caught catching coral reefs, punishment must be imposed.

The third point is the low number of people who support seminar activities on mangroves and coral reefs. People are sometimes lazy to take part in seminar activities. That is because the seminar activities are one-way and monotonous. The community prefers if the activity is carried out actively and directly goes to the field[22,23]. Environmental education community network (EECN) is one solution that can be done to overcome the low desire of the community to attend the seminar. That is because EECN has activities that are not boring, many field activities that can be followed by community[24].

Activities that can be carried out to socialize the importance of protecting coral reefs can use social media such as Twitter, Instagram, and Facebook[25–27]. That is because the millennial generation is the dominant respondent. They tend to easily access information about coral reefs and mangroves with digital technology. These technology advances make it easier to convey information to the public. The cost required is also not too large, different from using print media that requires costs to print [28,29].Efforts to improve community attitudes must be enhanced by environmental education. There must be a change in mindset in the community regarding environmental education [30,31].

Conclusion

Based on this research, it can be concluded that the attitude score of the community has been categorized as very high. Meanwhile, the age range of most respondents who filled the instrument was in the age range of 16-20 and 21-25 years. Respondents live in various big cities such as Jakarta, Bogor, Depok, Tangerang, and Bekasi, and other cities. Further efforts that need to be made are conducting more interesting seminars so that the community participates. One of them can use EECN.

The Effect of Wuluh Starfruit Leaf Extract (Averrhoabilimbi. L) on Malondialdehyde (MDA) Levels in Male Rats (Rattus Norvegicus) Hyperglycemia Model

Clara Nanlohy[1], Merryana Adriani[2], R. Bambang Wirjadmadi[2]

[1]Student in Master of Public Health, [2]Lecturer in the Department of Nutrition, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Starfruit leaf extract (*Averrhoabilimbi. L*) contains flavonoids as antioxidants that can prevent increased levels of Malondialdehyde (MDA) in hyperglycemia. Starfruit leaf extract can reduce oxidative stress conditions that trigger an increase in MDA levels. This study wanted to determine the effect of giving starfruit leaf extract on MDA levels in hyperglycemia rats from Wistar strain. This study was a completely randomized experimental design using 30 Wistar hyperglycemia rats for 14 days. The treatment group was given starfruit leaves extract of 200 (P1), 400 (P2) and 800 mg per kg of body weight (mg/kg bw) (P3) per day. Furthermore, on the 15th day, MDA levels were measured using a spectrophotometer. The results showed that there was an effect of giving starfruit leaf extract with various doses on MDA levels ($p = 0.001$), with an effective dose of P1 because it could prevent an increase in MDA levels.

Keywords: *Hyperglycemia, Malondialdehyde (MDA), starfruit leaf extract.*

Introduction

Diabetes mellitus (DM) is a metabolic disease with several etiologies characterized by chronic hyperglycemia due to impaired carbohydrate, fat and protein metabolism. This condition occurs because of abnormalities in insulin secretion, insulin acting on cell receptors, or both that causes an increase in blood sugar levels[1]. Patients are declared to have diabetes if blood glucose levels during fasting are more or equal to 126 mg/dL, or blood sugar levels for two hours fasting of more or equal to 200 mg/dL. The number of DM sufferers in 2015 of 425 million will increase to 629 million by 2035, which is almost 80% of the population of developing countries in the age range 29-79 years[2]. Indonesia, as one of the developing countries, is ranked 4th with the highest DM in the world after India, China and the United States.

Hyperglycemia as a sign of diabetes mellitus can be a cause of the formation of Reactive Oxygen Species (ROS) so that it can increase oxidative stress and also various complications in patients with diabetes mellitus[3]. Interaction of ROS with lipid bilayer will produce lipid peroxidation. Malondialdehyde (MDA) as one of the most significant lipid peroxidation reactions that can be used as a biomarker of the degree of oxidative stress in hyperglycemia[4].

Treatment of DM requires a long time-even a lifetime. Various DM treatments can be done, among others, by replacing insulin through multiple subcutaneous, as well as pancreatic cell transplant therapy, but this does not give good results[5]. The use of chemical drugs in oral antidiabetic groups of sulfonylurea, meglitinide and biguanide haveside effects - besides curing DM. Treatment of DM by utilizing natural ingredients is now beginning to be used and developed because natural ingredients are considered not to cause adverse effects

to the body when compared to the use of chemical drugs. Also, the use of traditional medicinal plants has increased because traditional medicines are safe, effective, efficacious and have minimal side effects[4].

One of the plants that can be used as antidiabetic and antioxidant medicinal plants is Wuluhstarfruit (*Averrhoabilimbi L.*). This plant contains flavonoid substances that can be used in the treatment of DM. Research that has been done on this plant states that Wuluhstarfruit leaf is reported to have antidiabetic and antioxidant properties, where the extract of starfruit leaf extract contains flavonoids, saponins, vitamin C and tannins[6]. Other studies also mentioned that starfruit leaves contain active substances, one of which is flavonoids as antidiabetic and antioxidant[7]. Wuluhstarfruit is widely known by the people of Indonesia because they consumed it as sweets and vegetables.

In patients with hyperglycemia, levels of free radicals in the body usually increase. This condition happens due to oxidative stress as one of the triggers for increased lipid peroxide in the cell membrane that produces Malondialdehyde (MDA). This study aims to determine the effect of Wuluhstarfruit leaf extract in reducing MDA levels in male hyperglycemia models.

Materials and Method

This type of research is an experimental study with a post-test only control group design research design using a completely randomized design (CRD) in 30 Wistar strain male rats, 2-3 months old, healthy without blemishes with 150-200 body weight gram obtained from the Faculty of Medicine, Airlangga University. Rats were randomly divided into five groups and then recited for seven days, after which they treated for 14 days. The negative control group (K (-)) was given distilled water and standard feed without alloxan induction; control group (K (+)) given aquades + standard feed + alloxan; P1 treatment group was given standard feed + alloxan + starfruit leaf extract dose of 200 mg/kg bw (body weight); P2 treatment group was given standard feed + alloxan + starfruit leaf extract dose of 400 mg/kg bw; P3 treatment group was given standard feed + alloxan + starfruit leaf extract dose of 800 mg/kg bw. The material of this research is the extract of fresh starfruit leaves.

The instruments used in this study were spectrophotometer (Tuner SP-870), vortex mixer (Thermolyne), centrifuges (Biofuge 15 series, HeracusSepatech), blood glucose test meters (GlucoDr), hemocytometers, digital scales, minor surgical sets, water baths, gastric-sonde, micropipettes, test tubes, glass objects, sterile syringes, Petri dishes, watch glasses and mouse cages equipped with eating and drinking utensils. The ingredients used are alloxan, starfruit leaf extract, 70% alcohol, 10% chloroform, 0.3% Na Cl solution, 0.9% Na Cl solution, distilled water, HCL IN, Na-Thio and 0.67% TBA.

Ethanol extract of starfruit leaves made by drying and extracting the leaves using the method of Maseri, namely leaves of starfruit leaves used as powder sifted using a mesh sieve number 40, weighed 200gr then extracted using 96% ethanol solvent as much as 5 L by means of Maseri 3 x 24 hours protected from sunlight by tightly stirring. Starfruit leaf extract then filtered using filter paper and then obtained the filtrate. Furthermore, evaporated or separated by using a Rotary Vaccum Evaporator at 60ºC, obtained a concentrated extract, then evaporated using a water bath at 60ºC until a thick starfruit leaf extract obtained. The extraction process of starfruit leaves was carried out in the biochemistry laboratory of the Faculty of Medicine, Airlangga University. Starfruit leaf extract (*Averrhoabilimbi L.*) is given one time a day for 14 days with the alloxan dose given to rats was 125 mg/kg BW intraperitoneally. The effects of hyperglycemia will appear after 72 hours. A rat was declared to have hyperglycemia if the blood glucose level examination was equal to or more than 200 mg/dL. After experiencing hyperglycemia, rats treated with starfruit leaf extract (*Averrhoabilimbi L.*) for 14 days. On the 15th day, malondialdehyde (MDA) levels measured.

On day 15, rat MDA levels examined at the Nutrition Laboratory of the Faculty of Public Health, Airlangga University, Surabaya. MDA levels were measured using the Thiobarbituric Acid Reactive Substance (TBARS) method by taking rat blood serum. The test was started by adding 100 µL of serum with 1 ml of Na Cl 0.9%, then centrifuged at 8,000rpm for 20 minutes. Then 550 µL of distilled water and 100 µL TBA were added. After homogeneous with vortex, added 250 µL HCL IN and re-vortex. Then 100 µL Na-Thio was added, homogenized by centrifuge at 500 rpm for 15 minutes. The supernatant formed is transferred to the new microtube then heated in a 100oC water bath for 30 minutes — absorbance measured with a UV-1601 spectrophotometer at a wavelength of 535 nm[3]. MDA examination using a spectrophotometer and the results of the examination were analyzed using SPSS 21 with a

significance level of 0.05 and a confidence level of 95% (α = 0.05).

Results

This research was conducted to test the effect of Wuluhstarfruit leaf extract (*Averrhoabilimbi L.*) in reducing Malondialdehyde (MDA) levels using 30 male Wistar strain rats, which divided into five groups. The results of measurements of rat MDA levels showed in Table 1.

Table 1. Malondialdehyde (MDA) levels in rats

Parameter	K(-)	K(+)	P1	P2	P3
The average of MDA levels in rats (ug/ml)	89.00±8.03	148.80±32.56	88.80±18.185	99.40±21.69	90.40±21.69

It explained that there were significant differences in mean serum MDA levels between treatment groups ($p < 0.05$). The highest group in the K group (+) was 148.80 ± 32.56 (ug/ml) and the lowest in the P1 group was 88.80 ± 18.185 (ug/ml). The results of normality and homogeneity tests ($p > 0.05$) showed that MDA levels were normally distributed ($p = 0.192$) and homogeneous ($p = 0.085$). Based on the results of Tukey HSD, there were significant differences in the mean MDA levels in the five treatment groups with a value of p = 0,000 (α = 0.05).

MDA levels in the group of rats without giving starfruit K(+) leaf extract significantly increased $p = 0.011$ ($p < 0.05$) compared to MDA levels in normal K (-) rats. MDA levels of the rat treatment group with oral administration of starfruit leaf extract dose of 200mg/kg BW (P1), 400mg/kg bw (P2), 800mg/kg bw (P3), decreased compared with control group K(+) which evidenced by the p-value <0.05 which means there is a significant difference in the serum MDA levels of experimental animals in the three treatment groups P1, P2, P3 compared with the positive control group K(+). MDA levels of treatment group P2 increased when compared with treatment group P1 showed a significant difference, evidenced by the value of $p = 0.001$. MDA levels of the P3 group approached the P2 group, evidenced a significant difference between the MDA levels of the P2 and P3 groups, with a value of $p = 0.016$ ($p > 0.05$). These results indicate that administration of Wuluhstarfruit leaf extract can reduce serum MDA levels in hyperglycemic mouse models in the P2 and P3 groups. Star fruit leaf extract with an effective dose of P1 200 mg/kg bw could reduce the serum MDA levels of rats because P1 was close to normal in group K(-).

Discussion

Malondialdehyde (MDA) is a lipid peroxide product and is used as an indicator to measure the presence of oxidative stress in the body while showing the number of free radicals in the body. Increased free radicals in the body can be suppressed and prevented by antioxidants.

Hyperglycemia causes an increase in oxidative stress through glucose auto-oxidation producing α-hydroxy-aldehyde, which will form radical reactive oxygen species (ROS) namely superoxide (O_2), hydroxyl radical (OH) and hydrogen peroxide (H_2O_2)[8]. Second, hyperglycemia caused accumulation of sorbitol and fructose due to increased aldose reductase activity and decreased intracellular NADPH and it will cause a decrease in endogenous antioxidants namely glutathione reductase (GSH) and increase in NO-ROS[8]. Third, hyperglycemia will increase glucose binding to amino and protein and this results in the formation of Advanced Glycation end Product (AGE) and ROS in vascular cells. Fourth, hyperglycemia increases the synthesis of Produced Glycerol (DAG) and protein kinase C (PKC) which causes an increase in intracellular radicals (superoxide and peroxide) due to an increase in NADPH oxidation[9]. If ROS meets PUFA, it will form lipid radicals, peroxyl radicals and various aldehyde compounds[10].

Oxidative stress due to high ROS due to chronic hyperglycemia triggers DNA damage and cell membrane damage. Hyperglycemia has a significant increase in MDA levels and lipid peroxidation because it is not matched by an increase in the body's endogenous antioxidants such as glutathione, glutathione reductase, glutathione peroxidase which have decreased levels[11].

The results of this study explain that the MDA levels

in the hyperglycemia group without starfruit leaf extract (K) showed an increase of 148.80 ± 32.56 (µg/ml) when compared with other groups. This study shows the results that the average MDA levels of rats significantly decreased in all three groups of hyperglycemic rats given starfruit leaf extract P1 dose 200 mg/kg bw, P2 dose 400 mg/kg bw, P3 dose 800 mg/kg bw, compared to the group K (+). The dose of P1 (200 mg/kg bw) as an effective dose in reducing serum MDA levels in rats because of the role of the active substance flavonoids and vitamin C contained in the extract of starfruit leaves that play an active role as antioxidants in preventing lipid peroxide in cell membranes and this result is supported by previous research[7].

The mechanism of starfruit leaf extract in reducing hyperglycemia and oxidative stress is inseparable from the active ingredient of flavonoid compounds that function as antidiabetic and antioxidant substances. Flavonoids work to protect lipid membranes from oxidative damage, so they can inhibit lipid peroxidation so that there is no increase in MDA levels in the body[6]. Also, if there is an excess production of reactive oxygen species (ROS), it can cause oxidative imbalances in the body. Flavonoids work to prevent plasma membrane damage from free radicals and also reduce MDA levels[7].

The content of flavonoids in starfruit leaf extract has the ability as an antioxidant and prevent damage from free radicals. Flavonoids act as scavenger free radicals directly (flavonoids-OH), can also be a scavenger of free radicals peroxyl (ROO *) which will be regenerated into ROOH. Flavonoids can also act as hydroxyl radical scavenger (OH *), which will be regenerated into H_2O. Peroxyl radical and hydroxyl radical regeneration compounds are more stable, while phenoxyl radicals that formed (flavonoids-O *) become less reactive to carry out the propagation reaction[12]. The stability of phenoxyl radicals is reported to reduce the rate of propagation reaction in the process of lipid autoxidation[12].

Conclusion

The results of this study indicate that the administration of Wuluh starfruit leaf extract (*Averrhoabilimbi L*) can reduce the levels of Malondialdehyde (MDA) in male rats (*Rattus Norvegicus* Wistar strain) hyperglycemia model. Giving starfruit leaf extract with a dose of P1 200 mg/kg bw for 14 days is an effective dose that can reduce MDA levels in experimental rats.

Factors Related Towards Patient Length of Stay in Emergency Department City of Batu, East Java, Indonesia

Dewi K. Ningsih[1], Hanifah I. Ritmadiani[2], Annisa W. Kartika[3], Ikhda Ulya[1], Asti M. Astari[4]

[1]Department of Emergency Nursing, School of Nursing, Universitas Brawijaya, Malang, [2]General Nurse at Petrokimia Gresik Hospital, Gresik-East Java, [3]Department of Community Health Nursing, [4]Department of Maternity Nursing, School of Nursing, Universitas Brawijaya, Malang, Indonesia

Abstract

Introduction: Patient LOS in the emergency department is affected by various factors. This study aimed to investigate the correlation among three factors related to patient LOS in the emergency department, which are: waiting time for laboratory test results;drug services in pharmacy department; and patients transfer time to inpatient room.

Method: This study employed an observational analytic method using a prospective cohort study approach. Samples were chosen by means of consecutive sampling with total of 44 patients within 14 days. The instruments used were observation notes detecting patient LOS and a wristwatch. Spearman's correlation rank was used to analyze correlation among the factors affecting the patient LOS in the emergency department.

Results: Spearman's test showed that the waiting time for laboratory test results (p = 0.830; r = 0.033) and drug services (p = 0.703; r = 0.059) were not significant, whereas patients transfer time to the inpatient room was statistically significant (p = 0.000; r = -0.699). Thus, among the three factors investigated, there was a significant correlation between patient transfer times to the inpatient room and patient LOS in emergency department.

Conclusions: It can be concluded that patient LOS are affected by patient transfer flow. Therefore, it is necessary to evaluate patient transfer flow along with the additional number of available beds.

Keywords: *Length of stay (LOS); transfer time; cohort-prospective study; East Java-Indonesia.*

Introduction

The emergency department (ED) is one of pivotal units in a hospital that provides early treatment for patients suffering from illnesses and wounds that potentially threaten their life. The ED offers immediate, accurate and meticulous aids to prevent death and body impairment (time-saving is life-saving)[1,2]. Morbidity and mortality rates were fairly high,especially for trauma cases[3]. Therefore, it is strongly required to improve and enhance both quantity and quality of ED services.

There are three indicators to measure healthcare performance in the ED; namely door to doctor (Dt D), length of stay (LOS) and holistic service satisfaction. Among these three indicators, LOS plays a crucial role. LOS is the embodiment of a hospital's commitment to providing better services[4]. LOS is defined as time explaining patient from being admitted to a triage room and time they are allowed to discharge [5]. LOS has been set by international standards to last ≤ 8 h[6]. The National Emergency Access Target (NEAT), Australia, has recommended that starting from 2016, LOS in the EDhas been set at a maximum of 4 h and similarly its happened in the UK in 2004[7].

Most EDs in Indonesian hospitals are still basing their criteria on the regulation by Ministry of Health (MoH) Number 129/Menkes/SK/II/2008, stated that patient LOS is 8 h; and when its compared to other standards set internationally, LOS in Indonesia is longer. LOS is affected by several factors; among of these are laboratory tests, examination, final decision of physical tests, response to final decision, period of consultation and management of critical patient [8]. In addition, LOS is affected by triage status, the limited number of available beds in the inpatient care room and the limited number of health care practitioners [9-14].

In most Indonesian hospitals it has found that patient age, triage status and administrative matters affect LOS. Triage status often requires patients to stay longer in the ED as it correlates with some necessary treatments [15, 16]. The prolonged period of LOS in the ED affects patient satisfaction, service effectiveness, patient safety, as well as patients' mortality and morbidity rates[12,17]. While in the emergency department of Karsa Husada Public Hospital Batu, LOS is affected by several factors which are patients transfer time to the inpatient room, limited number of health care personnel, waiting time for laboratory test results and drug services from the pharmacy department. Therefore, a study about the correlation among those of three factors which are waiting time for laboratory test results;drug services in pharmacy department; and patients transfer time to inpatient room are of essential to conduct in regard to examine whether three of mentioned factors contribute to patient LOS in the emergency department.

Material and Method

Our research investigated factors that affected patient LOS included waiting time for laboratory test results, drug services from the pharmacy department and patients transfer time to the inpatient room; and length of stay patients in the ED. Waiting time for laboratory test results, drug services from the pharmacy department and patients transfer time to the inpatient room were stated as time using to deliver each of services. In addition, length of stay was defined as time used by patient from being admitted to triage room and to the time where patient are allowed to transfer into inpatient room.

This prospective cohort study was employed to investigate the correlation between waiting times for laboratory test results; drug services from the pharmacy department and patients transfer time to the inpatient room with patient LOS. A non-probability sampling method by means of consecutive sampling was used. Samples were obtained during 2 weeks (14 days) of observation resulted in total of 44 investigated patients.

This study was conducted in the ED of Karsa Husada Public Hospital, Batu, on 6 February to 19 February 2017. Data were taken during morning, afternoon and night shifts. The instruments used to collect data were observation notes detecting patient LOS and a wristwatch. The time standards taken as the basis for this current study were as follows: ≤ 140 min for the waiting time for laboratory test results, ≤ 30 min for off-the-shelf drugs and ≤ 60 min for compound drugs as the waiting time for the medicine service in the pharmacy department and ≤ 2 h for the transfer of patients to the inpatient care room. Data collected by noting down the waiting time for each patient for each variable and checking whether it fitted the set time standard in the hospital. Statistical tests were made on the collected data to investigate the correlation among factors that affecting patient LOS in the ED.

Findings:

Table 1. Descriptive statistics of all variables

Variable	n	(%)
Total respondents	44	100
Gender		
Male	26	59.1
Female	18	40.9
Age		
Infants	2	4.6
Children	7	15.9
Adults	17	36.6
Elderly	18	40.9
Triage Category		
Red	11	25
Yellow	17	38.6
Green	16	25
Number of patients per shift		
Morning shift	24	54.6
Afternoon shift	10	22.7
Night shift	10	22.7
Number of relatives/persons for accompanying patients		
Accompanied by one person	16	36.4
Accompanied by more than one person	28	63.6

Variable	n	(%)
Number of health personnel in the emergency department per shift		
Morning shift	4 - 10	
Afternoon shift	3 - 6	
Night shift	3 - 5	
Distribution patient LOS in the ED		
Normal	42	95.5
Prolonged	2	4.5

Sources: Primary data (2017), N = 44

The distribution of patient demographics and all other variables are outlined in Table 1 of the 44 investigated patients 40.91% were female and 59.09% were male and there were 40.91% elderly, 38.64% adults, 15.91% children and 4.55% infants. For triage category, 38.64% of patients were in the category of triage P2 (yellow), 36.36% of patients were in the category of triage P3 (green) and 25.00% of patients were in the category of triage P1 (red). Regarding the number of people who accompanying patients, 63.64% of patients accompanied with two people and 36.36% were accompanied by one person. Based on data distribution in term of number of patients per shift, there were 24 patients during morning shift, 10 patients for afternoon shift and 10 patients in the night shift. Whereas, the number of health personnel in the ED per shift were 4–10 personnel (morning shift), 3–6 personnel (afternoon shift) and 3–5 personnel during night shift. The distribution of patient LOS in the ED showed a majority was in normal category (95.5%), while a prolonged LOS was only seen in 4.5% among all the respondents.

Table 2. Factors affecting patient length of stay in the emergency department

	Variable	n (%)
1.	Waiting time for laboratory test result	
	Meet standard	43 (97.7)
	Did not meet standard	1 (2.3)
2.	Waiting time for drug services in the pharmacy department	
	Meet standard	41 (93.2)
	Did not meet standard	3 (6.8)
3.	Waiting time for the availability of beds in inpatient care room	
	Meet standard	43 (97.7)
	Did not meet standard	1 (2.3)

Sources: Primary Data (2017), N = 44

Table 2 presents an overview of factors affecting patient LOS in the ED including waiting time for laboratory test results, waiting time for drug services from the pharmacy department and waiting time for the availability of a bed in inpatient care. The results showed that among of these three factors had reached standard with percentages of 97.7%, 93.2% and 97.7%, respectively.

Table 3. Results for factors affecting patient length of stay (LOS) in the emergency department

Factor	Category	LOS			Spearman correlation rank	
		Normal	Prolonged	Total	r	p
Waiting time for laboratory test results	Standard	41	2	43	0.033	0.830
	Non-standard	1	-	1		
Waiting time for drug services	Standard	39	2	41	0.059	0.703
	Non-standard	3	-	3		
Waiting time for bed available into inpatient room	Standard	1	42	43	-0.699	0.000

Sources: Primary Data (2017), N = 44

Table 3 describes analysis using Spearman's correlation rank for each subvariable against LOS. The tests resulted in a correlational probability value p= 0.830(r = 0.033) on the subvariable of waiting time for laboratory test results and a correlational probability value p= 0.703 (r = 0.059) on the waiting time for drug services. This shows that there was no significant correlation between the waiting time for laboratory test results and the waiting time for drug services and patient LOS. This implies that the waiting time for the laboratory

test results and drug services in the ED is based on the set standard without any effect on patient LOS. In contrast, the statistical test was different for the subvariable of the waiting time for available beds in the inpatient room. The correlational probability value was $p = 0.000$ ($r = –0.699$), implying that there is a correlation between waiting time for available beds in the inpatient room and patient LOS. The correlation value was negative and significant; and it can be inferred that the longer the patients have to wait for available beds in the inpatient care room, the more prolonged was patient LOS.

The current study has found that majority of patients (97.7%)met standard time for getting laboratory test results. This is happened due to the fact that patients who accompanied by two people or more were relatively experienced shorter waiting time for laboratory test resultswith an average time of 63.03 min compared to only one person accompanying patient with time average of 72.37 min.Also, laboratory tests were highly correlated with triage status. The more severe patients condition, the more complex laboratory tests they must undergo. Patients in P1 category took on average 72.5 min to receive laboratory test results, while the time was 71.47 min for those in the P2 category and 53.307 min for category of P3. A previous study found that type of laboratory test affected of waiting time for laboratory test results [18]. The prolonged waiting time would cause a delay in immediate diagnosis and treatment.

Similarly, time needed for drug services is also found satisfactory with most of patients (93.2%) experienced met standard. An average times used to drug services was ranging from 17.92 min (patients accompanied by two people/more) to 19.87 min (patients accompanied by only one person/relative). However, patients are requiring more time towards drug services within morning shifts. It's resulted that non-standard required waiting times for drug services was still found in the morning and sometime afternoon shifts. This situation is in line with a previous study that showed overcrowding patient in ED and referral status of patientis associated with a prolonged waiting time during drug services[19].

Waiting time to transfer patient from the ED to the inpatient room was considered satisfactory, as 97% cases met set of standard in term of transfer time. The investigated transfer time from ED to inpatient room was considered fairly fast, ranging from 0–80 min. Data in this current study has shown that there was differences in term of average waiting times for transferring patients who accompanied by one person and/or more than one. An average LOS of patient with one person accompanied was about 242.750 min and it was shorter as compared to those who do accompany by two people/relatives, which is 121.17 min. This is occurred due to the fact that relatives are required to help immediately processes room registrations and administrations. Also, paper-based medical records can cause prolonged waiting time since it takes time to manually filled.

In addition, triage status is affected by time wait in terms of transfer patient to the inpatient room. There was on average 193.57 min LOS for patients with P1 category, 157.94 min for P2 and 144.76 min for P3 category. The most severe patient, the more time its required. This implies that the higher emergency status of patient, the more prolonged was their LOS [16]. It is in line with study done in Dr.T.C. Hillerrs Maumere Hospital stated that 41% of patients experienced LOS more than or equal to 6 h and factors that are contributed included triage status and administrative matters[22]. In addition, overcrowding patient causing long queues for assessing examination by health care personnel, which also affects patient LOS [23].

Conclusion

Factor affecting patient LOS in the ED of Karsa Husada Public Hospital was varied, however, the most relevant factor that contribute is patient's waiting time to get transfer to the inpatient room. Effort to prevent a prolonged LOS is urgent and need to be done throughout evaluating patient transfer flow from the ED to the inpatient room and improving beds capacity in room/units.

Apoptosis Index of Cerebrum and Cerebellum Neuronal Cells in Rattus Norvegicus Neonates Born from Mother Treated with Mozart, Javanesegamelan, Sundanesegamelan and Balinesegamelan During Gestation

Fitria Ardiyani[1], Hermanto Tri Joewono[2], Widjiati[3]

[1]Department of Reproductive Health Science, [2]Department of Obstetrics And Gynecology, Faculty of Medicine, [3]Department of Embriology, Faculty of Veterinary Medicine, Universitas Airlangga, Dr. Soetomo Hospital, Surabaya, Indonesia

Abstract

Background: Newborn *Rattus norvegicus* expose to Mozart's music prove lower than those expose to Javanese, Sundanese and Balinese music. Exposure to classical music such as Mozart, Javanese, Sundanese and Balinese gamelan can increase waves of brain activity. Mozart's music during pregnancy proved to reduce neuronal cell apoptosis.

Objective: The purpose of this study was to analyze differences in the index of neuronal apoptosis in the *cerebrum* and the newly born Rattus norvegicus *cerebellum* between those exposed to Mozart music, Javanese, Sundanese, Balinese and those who were not exposed to music during pregnancy.

Method: The female subjects of pregnant *Rattus norvegicus* were divided into 5 groups randomly each with 5 samples, 1 control group and 4 treatment groups. after the 10th day of pregnancy music was played for 1 hour in a dark soundproof box with a intensity of 65dB. The 19th day of the parent was sacrificed and *sectio caesarea* was taken, 3 newborn *Rattus norvegicus* children were taken with the heaviest, moderate and mildest and brain tissue was taken for preparation.

Result: The ANNOVA test results showed significant differences between groups with p = 0.01 in the *cerebrum* and p = 0.000 in the *cerebellum*.Conclusion: It can be concluded that the apoptosis index of *cerebrum* neuron cells and the newly born *Rattus norvegicus cerebellum* exposed to Mozart's music proved to be lower than those exposed to Javanese, Sundanese and Balinese gamelan music.

Keywords: *Mozart, Javanese gamelan, Sundanese gamelan, Balinese gamelan music Stimulation; neuronal apoptotic index; Rattus norvegicus.*

Introduction

During pregnancy there is an organogenesis process in which the first formed is hearing, vision and heart. The organogenesis process occurs in the formation of the brain where brain cells undergo proliferation, migration, differentiation, synaptogenesis, myelinization and apoptosis[2]. Stimulation that is easy to do is by sound, a harmonious sound will be more easily accepted by the fetus, a harmonious sound is called music[1].

Indonesia has a lot of traditional music including Balinese, Javanese and Sundanese gamelan music, Indonesian music is certainly better known by the Indonesian people and is easily enjoyed by all Indonesian

people. States that gamelan music has a character similar to classical music[3]. The results of the study, namely classical music, has a structure of amplitude that is higher and slightly decreases at the upper hearing threshold frequency (20 kHz). The dominant frequency is at 4-7 kHz bandwidth and the vocal frequency (800-1500 Hz) is not dominant, traditional Javanese songs, Sundanese and Balinese have a higher amplitude structure and slightly lower at the upper hearing threshold frequency (20 kHz), the dominant frequency is at 4-7 kHz bandwidth and vocal frequency (800-1500 Hz) is not dominant. Third, based on the results of the study, traditional Sundanese, Javanese and Balinese songs have identical values with classical music (Mozart's Symphony 40) of 71.34% in terms of the level of identification of frequency dominance and 71.31% seen from the level of identification of frequency occurrence[4].

This music stimulation is given at 20 weeks' gestation, for 1 hour, at night. Music is given in the mother's stomach, in the womb the wave is attenuated[6].

The scientific basis of the above process is that sound stimulation or music can reduce the number of physiological brain nerve cell death processes (apoptosis) and improve the relationship between brain nerve cells including morphological changes that are influenced by stimulation regularly so that babies at birth can have nerve cells and sinap more than those who did not get enrichment[5].

This study aims to determine the differences in the apoptotic index of cerebrum neuron cells and the newly born Rattus norvegicus cerebellum between those exposed to Mozart's music with Balinese, Javanese and Sundanese gamelan during pregnancy.

Material And Method

This research was Pathology Laboratory of the Faculty of Veterinary Medicine, Airlangga University, Surabaya. This study received an ethical feasibility permit based on the Ethics Commission The results of this study were using experimental laboratory research method, *posttest-only control group design*, obtained from laboratory experimental studies using 25 samples of *Rattus norvegicus* mothers. *Pregnant Rattus norvegicus* was given exposure to Mozart's music, Javanese gamelan music, Sundanese gamelan music and Balinese gamelan music for one hour with an intensity of 65 db in a soundproof box and without all the exposure after the 10th day of pregnancy. In this study all *Rattus norvegicus* mothers used birth with adequate pregnancy, namely between gestational age 19-20 days. There is no *Rattus norvegicus* mother who experiences preterm birth, abortion or death. Wistar strain *Rattus norvegicus* parent with a range of 110-120 grams after acclimatization. When pregnant, the parent body weight of *Rattus norvegicus* ranges from 130 - 180 grams, then randomization into 5 groups - each of the 5 parents. After 9 days of treatment with exposure to music, Music is presented by using Windows media player program with 65 dB intensity using Sound level meter, then all pregnant mother *Rattus norvegicus* was weighed before sacrifice. This is done to reduce weight bias. Then three newborn *Rattus norvegicus* children were selected with heavy, moderate and light weights and after that were immediately sacrificed by decapitation. Selected the heaviest, moderate and light weight. The cell apoptosis index of cerebrum neurons is known and calculated through immunohistochemistry which is characterized by brown cells,viewed with 5x visual field with 400 magnification after the sample counted the apoptotic index of neuron cells.To simplify statistical calculations, researchers used SPSS device aids using the ANOVA test followed by LSD to see differences in all groups.

Result

Subject Characteristics: This study used the Wistar strain *Rattus norvegicus* parent with a range of 110-120 grams after acclimatization. When pregnant, the parent body weight of Rattus norvegicus ranges from 130 - 180 grams, then randomization into 5 groups - each of the 5 parents. After 9 days of treatment with music exposure, then all pregnant mother's Rattus norvegicus is carried out weighing before sacrificing.The Shapiro-Wilk test showed a normal distribution of *Rattus norvegicus* mother weight data in groups with exposure to Mozart's composition and controls ($p > 0.05$).

Table 1 Mean body weight Rattus norvegicus mothers and offspring.

Group	BW Mothers			BW offspring		
	Mean	SD	p	Mean	SD	p
Control	119,8	3,34	0,211	0,49	0,03	0,561
Mozart	121,8	3,49		1,74	0,82	
Java	121,2	4,65		1,56	0,92	
Sunda	121,2	4,08		1,51	0,97	
Bali	120,2	4,14		1,30	0,66	

From the results of table 1, the data showed that the average body weight of the largest *Rattus norvegicus*

mothers came from Mozart's music group, which was 175.40 ± 5.98 grams, the lowest mean weight of *Rattus norvegicus* children came from groups without music exposure. While the weight of *Rattus norvegicus* children in the group without music exposure had a mean of 0.49 ± 0.03 grams. Main body weight data (p = 0.211) and children (p = 0.561) are normally distributed.

Table 2 The mean and standard deviation of neuronal apoptosis index in the new *Rattus norvegicus* cerebrum and cerebellum born from the mother exposed to Mozart music, Javanese gamelan, Sundanese gamelan, Balinese gamelan and not exposed to music

Group	Cerebrum			Cerebellum		
	Mean	SD	p	Mean	SD	p
Contrl	4,68	1,00	0,795	4,03	0,67	0,747
Mozart	2,28	0,60	0,549	2,04	0,55	0,656
Java	3,40	0,46	0,103	3,24	0,47	0,294
Sunda	3,48	0,72	0,884	3,28	0,48	0,071
Bali	3,56	0,77	0,375	3,35	0,53	0,581

Table 2 showed a mean index of neuronal apoptosis per 5x field of view in the newly born *Rattus norvegicus cerebrum*and *cerebellum*. The lowest average value was obtained in the Mozart music treatment group when compared to the Javanese gamelan music treatment group, Sundanese gamelan, Balinese gamelan and controls. Data on the number of neuron cells in all groups are normally distributed with p> 0.05.

Analysis of the results on cerebrum the results of the normality test showed that the apoptotic index data of cerebral neuron cells in all groups were normally distributed (p> 0.05). Therefore, to see the differences in all groups, the oneway Anova test was used.If the ANOVA test found a significant difference (p <0.05) then it was followed by the LSD (Least Significant Difference) test.

Table 3 Anova test results on neuron cell apoptosis index in the new *Rattus norvegicus* cerebrum born from mothers exposed to Mozart music, Javanese gamelan, Sundanese gamelan, Balinese gamelan and not exposed to music.

Neuron cell apoptosis index	p
	0,001

Based on table 3 shows the value of p = 0.001 which means there are significant differences in the index of neuronal cell apoptosis in the newborn *Rattus norvegicus* cerebrum.

Table 4 Post Hoc LSD test results The apoptosis index of cerebrum neuronal cells of *Rattus norvegicus* children was born from mothers exposed to Mozart's music, Javanese gamelan, Sundanese gamelan, Balinese gamelan and not exposed to music.

Group	p			
	Mozart	Java	Sunda	Bali
Control	0,000	0,013	0,019	0,027
Mozart		0,027	0,019	0,013
Java			0,866	0,736
Sunda				0,866

Table 4 shows the results of the LSD Post-Hoc test. The apoptotic index of cerebrum neuron cells in newborn *Rattus norvegicus* children in all comparisons of each group has significant differences.

Analysis of the results on cerebellum the results of the normality test showed that the apoptotic index data of cerebral neuron cells in all groups were normally distributed (p> 0.05). Therefore, to see the differences in all groups, the oneway Anova test was used. If the ANOVA test found a significant difference (p <0.05) then it was followed by the LSD test

Table 5 Anova test results on neuron cell apoptosis index in the new *Rattus norvegicus* cerebellum born from mothers exposed to Mozart music, Javanese gamelan, Sundanese gamelan, Balinese gamelan and not exposed to music.

Neuron cell apoptosis index	p
	0,000

Based on table 5 shows the value of p = 0.000 which means there are significant differences in the index of neuronal cell apoptosis in the newborn *Rattus norvegicus* cerebellum.

Table 6 Post Hoc LSD test results The apoptosis index of cerebellum neuronal cells of *Rattus norvegicus* children was born from mothers exposed to Mozart's music, Javanese gamelan, Sundanese gamelan, Balinese gamelan and not exposed to music.

Group	p

Sunda				0,842

Table 6 shows the results of the LSD Post-Hoc test. The apoptotic index of cerebellum neuron cells in newborn *Rattus norvegicus* children in all comparisons of each group has significant differences.

Discussion

There is a significant or significant difference in the neuron apoptosis index in the cerebrum and the newly born *Rattus norvegicus* cerebellum between the Mozart music group and the group not exposed to music. Mozart's music group and the group not exposed to music found that the average apoptotic index of Mozart's music group was lower than that of the group not exposed to music. This is consistent with research conducted on *Rattus norvegicus* given exposure to Mozart music during pregnancy compared to *Rattus norvegicus* who were not exposed to Mozart's music and obtained significant differences in the apoptotic index of the brains of children born to *Rattus norvegicus*. who received Mozart's music exposure had a lower apoptosis index than those who did not receive exposure[6].

The results of the study of music exposure to the Javanese gamelan music group at the age of 10-20 days for 1 hour with an intensity of 65 db in the soundproof box found that the index of apoptosis in the cerebrum and cerebellum of the Javanese gamelan music group was lower than the group not exposed to music. there was a significant or significant difference in the apoptosis index of neuron cells in the cerebellum and the new Rattus norvegicus cerebellum. Javanese gamelan music produces soothing alpha waves that can stimulate the limbic system of brain neurons. Javanese gamelan music can improve the concentration of memory and spatial perception[8].

Research on the cerebrum and cerebellum found that the average apoptotic index of the Sundanese gamelan music group was lower than the group not exposed to music, found a significant difference in the index of neuronal apoptosis in the cerebrum and the newborn *Rattus norvegicus* cerebellum in Sundanese gamelan music groups and groups not exposed to music. Gamelan music produces soothing alpha waves that can stimulate the limbic system of brain neurons. Gamelan music can improve memory concentration and spatial perception[10]. The musicality of the Sundanese gamelan degung is so soft that when you hear it the mind becomes more relaxed. Likewise repetitive music structures and cycles make it easy to learn. The lack of conductors emphasizes the need to listen to others, which may be the developmental skills handled in music therapy. Instruments, which have been previously set, meet a variety of abilities and levels of experience, which are also important in therapeutic settings and tone and sound waves may have therapeutic relevance[11].

This is according to the theory revealed, the brain needs energy. The best energy is sound. The type of music that can increase the number of brain cells, is Mozart's classical music that can be used with a frequency of 5000-8000 Hz which is dominated by a major tone and a slight minor tone. With this frequency, the intensity is not too high and is considered appropriate for the fetal environment during pregnancy[7].

The results showed that the average index of apoptosis in the cerebrum and cerebellum in the Mozart music group was lower than the Javanese gamelan music group, Sundanese gamelan music, Balinese gamelan music and not exposed to music. Although the frequency possessed by Gamelan music is higher than Mozart's music, which is 15,000 Hz, but in this music there are more minor tones. Minor tones compared to the major tones activate the amygdala, retrosplenal cortex, brain stem and cerebellum[19] . Music Mozart has a melodic rhythm and frequency that can stimulate creative and motivational areas in the brain[15].

Conclusion

Apoptosis index of cerebrum neuron cells and the new *Rattus norvegicus* cerebellum exposed to Mozart's music proved to be lower than those exposed to Javanese, Sundanese and Balinese gamelan music.

Relationship between Intention and Motivation Pregnant Women of High Risk to Decision Making of Referral at Sidotopo Wetan Health Center of Surabaya, Indonesia

Iftitahul Mustaadah[1], Ernawati[2], Rachmat Hargono[3]

[1]Master of Public Health Program, Faculty of Public Health, [2]Department of Fetomaternal, Faculty of Medicine, [3]Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Airlangga University Surabaya, Indonesia, 60115

Abstract

Background: One of the main obstacles to the slow decline in MMR in Indonesia is the obstacle to making referral decisions for high-risk pregnant women. This referral decision making is an illustration of the process of improving maternal and fetal health conditions as well as a complex process involving stages such as understanding the existence of a problem, finding alternative solutions to problems and evaluating alternatives that ultimately to decide on referrals to high-risk pregnant women can be done own mother quickly and precisely. Determining the health of high-risk pregnant women is the mother herself, not someone else. If the individual has strength and confidence, then motivation and intention will be formed in carrying out an action even when faced with obstacles.

Material and Method: The study used a quantitative approach with observational analytic type using cross sectional design. In this study the sample was pregnant women who had an indication to be referred to the hospital at the Sidotopo Wetan Health Center in Surabaya

Result: The results of the analysis show intention (p = 0,000) and motivation (p = 0,000) have a significant relationship to decision making referrals in pregnant women at the Sidotopo health center in Surabaya.

Conclusion: Pregnant women who have high intention and motivation have a tendency to be willing to make well referral decisions to realize their goals.

Keyword: *Motivation, intention, referral.*

Introduction

Around 830 women die from complications related to pregnancy or childbirth around the world every day. Almost all of these deaths occur in low-resource settings and most can be prevented. 99% of all maternal deaths occur in developing countries. Maternal mortality is higher in women who live in rural areas and among poor communities[1].

The maternal mortality rate in ASEAN tends to vary, overall the MMR in ASEAN in 2015 amounted to 197 per 100,000 live births [2] . The trend of maternal mortality in Surabaya in 2013 was 119.15 per 100,000 live births, in 2014 it was 90.19 per 100,000 live births, in 2015 it was 87.35 live births and in 2016 it was 85.72 per 100,000 live births[3].

This is based on the fact that one of the main obstacles to the slow decline in MMR in Indonesia is

the obstacle to decision making referrals to high-risk pregnant women. This referral decision making is an illustration of the process of improving maternal and fetal health conditions as well as a complex process involving stages such as understanding the existence of a problem, finding alternative solutions to problems and evaluating alternatives that ultimately to decide on referrals to high-risk pregnant women can be done own mother quickly and precisely. Determining the health of high-risk pregnant women is the mother herself, not someone else [4] .If the individual has strength and confidence, then motivation and intention will be formed in carrying out an action even when faced with obstacles[5].

Based on the above background, the researcher wants to conduct a study entitled the relationship between intention and motivation of pregnant women with high risk for decision making referrals at the Sidotopo Wetan Heatlh Center Surabaya

Materials and Method

The study used a quantitative approach with observational analytic type using cross sectional design. In this study the sample was pregnant women who had an indication to be referred to the hospital at the Sidotopo Wetan Health Center in Surabaya . The sampling is done by simple random sampling. Measurement scale to see independent variables using Likert scales. Scores are grouped in two categories . Data analysis was carried out using nonparametic statistical tests namely logistic regression analysis using SPSS.

Result

Table 1. Intention and Motivation on Referral Decision Making in the Sidotopo Wetan Health Center in 2019

Variable	Referral Decision Making				Total
	Ready	(%)	Not willing	(%)	N
Intention					
High	40	87.0	6	13.0	46
Low	14	56.0	11	44.0	25
Total	54	76.1	17	23.9	71
Motivation					
High	33	89.2	4	10.8	37
Low	21	61.8	13	38.2	34
Total	54	76.1	17	23.9	71

Table 1 . shows the results that pregnant women who have high intention and low tend to be willing to take referral decisions. While pregnant women have a motivation high and low also tend to be willing to take the referral decision

Table 2. Effect of Intention and Motivation on Referral Decision Making in the Sidotopo Wetan Health Center in 2019.

Variable	Referral Decision Making		Information
	p-value	Exp (B)	
Intention	0,000	6,667	Significant
Motivation	0,000	8,250	Significant

Table 2 shows the results of nominal logistic regression analysis. The intention and motivation variables are statistically proven to significantly influence referral decision making .

Discussion

Intention indicates that someone intentionally tried and planned to display the behavior. Intention is a very important foundation or basis for every behavior/action, even a barometer of every behavior/action. The value of a behavior is very dependent on intentions, if good intentions then the behavior will be good. Conversely, if bad intentions then the behavior becomes bad. Intention as a way to achieve a goal. Intention is a mental process that is realized and arises from the human will itself, which includes cognition (feeling and receiving), konasi (effort, willingness, desire, desire) and feelings (loving, hating). So it can be concluded that intention is the likelihood of someone to bring up the behavior and how strong an effort is made to display the behavior[6].

Statistical test results on the effect of intention on referral decision making found that intention affects the referral decision making. The results of this study are in line with previous studies. Sheeran (2012) in a meta-analysis of the relationship between intention and behavior explains that intention is the key to one's readiness to perform a behavior[7].

Motivation is a condition in a person that drives an individual's desire to carry out certain activities in order to achieve a goal. The existence of desires and needs in individuals, motivating these individuals to fulfill them. Efforts of pregnant women to implement more adequate health service referrals can be achieved when individuals are motivated to look for needs at a higher stage, so that individuals will have the ability to solve problems[8].

Statistical test results of the effect of motivation on referral decision making found that motivation affects the referral decision making. The results of this study are in accordance with the theories that have been explained and are in line with previous research conducted by Sigit Prasojo (2015) which explains the results of the descriptive study showed 63% of respondents with high motivation and 37% of respondents with low motivation. High motivation on respondents is indicated by good antenatal care visits while low motivation on respondents is indicated by poor antenatal care visits[9].

Conclusion

Intention and motivation variables affect the referral decision making. Pregnant women have a high intention to have a tendency willing to take the referral decision by 6.667 times compared with pregnant women who have low intention. Pregnant women who have high motivation have a tendency to take referral decisions by 8,250 times compared to pregnant women who have low motivation. So that in a decision making referral by pregnant women requires intention and motivation.

Acknowledgments: On this occasion the author would like to thank the respondents who honestly filled out the questionnaire that had been given.

Efficacy of Local Food-Based Tabaro dange Against Weight of Gain and Levels of Hemoglobin (Hb) White Rats (Rattus Norvegicus Strain Wistar)

Jenita Frisilia[1], Annis Catur Adi[2], Rita Ismawati[3]

[1]Student Master of Public Health at Airlangga University Surabaya, [2]Department of Nutrition, Faculty of of Public Health, Airlangga University Surabaya, [3]Department of Family Welfare Education, Faculty of Engineering, Surabaya State University, Indonesia, 60115

Abstract

Disasters can cause blocked logistical access locations. This causes special disaster victims for children to be difficult to get food, as a result, the nutritional intake for the growth and development of infants cannot be met according to their needs. Utilization of local food can be an alternative in providing emergency food that is rich in energy needs to prevent the expenditure of malnutrition. This study aims to determine the effectiveness of the administration of Tabaro on body weight and levels of white rats (rattus norvegicus). This research is experimental with a randomized design post-test only control group design. Randomly selected samples (CRD) were divided into 4 groups, as much as 4 g/rat/day, each maintained by individuals for 14 (fourteen) days. The sample used was 24 male white rats (Rattus norvegicus). Statistical test results showed an increase in body weight in each group with a p-value <0.05 ($\alpha = 0.054$) and a significant increase in Hb levels in each group that managed a p-value <0.05 ($\alpha = 0.001$). Giving Tabaro dange snacks based on local food can increase body weight and hemoglobin levels in male white rats (Rattus norvegicus). Obtained from further research to learn about the acceptability of the Tabaro dange can be used as a rationed product in an emergency.

Keyword: *Body weight, hemoglobin (Hb) levels, local food, tabaro dange.*

Introduction

Most of Indonesia's territory is in disaster-prone locations. This can lead to blocked access to food so that the impact of disaster victims has decreased nutritional status due to lack of energy for quality food.() Not all regions in Indonesia have good infrastructure and make it easy for people to access good and healthy food.

Foods not only contain macronutrients such as carbohydrates, fats and proteins that can produce energy but also contain micronutrients such as vitamins and minerals.() Lack of food intake, in the long run, will also cause a lack of micronutrient intake or micronutrient deficiencies. The condition that often accompanies protein and micronutrient energy malnutrition is anemia. Anemia is a state of decreased levels of hemoglobin (Hb), hematocrit (Ht) and red blood cells below normal values. () Contain nutritional needs to meet the daily consumption requirements for toddlers (1125-1600 kcal/day) in order to avoid new disasters after natural disasters, such as the emergence of hunger, so that emergency food must be given at least meet the additional food needs of 10-15% of the nutritional adequacy rate (RDA) for infants.()

Emergency food is given aiming to prevent disease and even death due to starvation during disasters.() One alternative to deal with cases of malnutrition in an emergency is to use Moringa leaves as an alternative

Jenita Frisilia
Student Master of Public Health at Airlangga University Surabaya, Indonesia, 60115
e-mail: jenita.frisilia-2017@fkm.unair.ac.id

food. One of the uses of Moringa leaves is processed into a traditional snack based on local food. Tabaro dange is a typical hammer food based on local food that can be used as food "ready to use food". Tabaro dange is made from a mixture of sago flour, cassava flour and grated coconut served with additional contents in it, such as brown sugar and anchovies.() Because tabaro dange is made from sago flour and cassava flour so it is rich in carbohydrates which can contribute energy to meet calorie needs in an emergency.

Various types of emergency food have been developed using local food. Based on the background description, this study aims to prove whether the administration of tabaro dange can increase body weight and hemoglobin levels during the treatment process of body weight of rats (Rattus norvegicus).

Method

The study was conducted in the biochemistry laboratory of the Faculty of Medicine, Airlangga University on July 11 to August 7, 2019. The type of research used was a randomized post-test only control group design where randomly selected samples (CRD) were divided into 4 groups, consisting of 1 control group, namely the control (K) and 3 treatment groups namely P1, P2 and P3. The giving of Tabaro dange starts on the 1st day after the adaptation period for one week until the 14th day. The research design is presented in Figure 1.

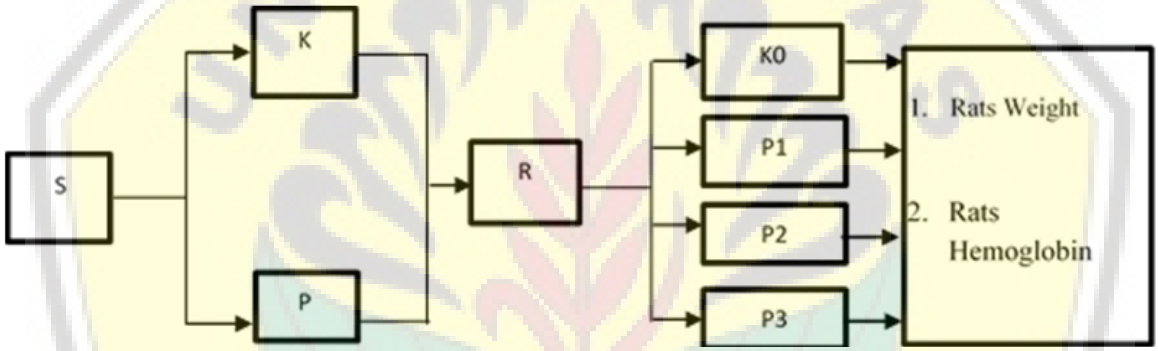

Figure 1. Experimental Research Design

Information:

S : Experimental animal (white rat Galur Wistar)
K : Control Group
P : Treatment group
R : Grouping rats by random sampling
K0 : Control group (pellet administration)
P1 : Tabaro dange based on
P2 : Provision of Tabaro and substitute purple sweet potato flour and Moringa leaf
P3 : Tabaro administration with yellow sweet potato flour and purple sweet potato and moringa leaf substitution

The experimental unit used in this study was a male white rat (Rattus norvegicus) male Wistar strain aged 3-4 months with body weight around 150-200 grams, with the inclusion criteria there were no anatomical abnormalities that appeared healthy. With replication 6 times. To overcome if there is an error in the study, a sample reserve is needed. To anticipate the loss of the dining experiment unit a correction is performed with 1/(1-f) where f is the proportion of the experimental unit that dies or fails. In this study using f = 10%.

Rats were grouped into two groups randomly, namely the control group and the treatment group. The control group was given standard feed and the treatment group was divided into three groups that were given the Tabaro dange snack bar (P1), the group that was given the Tabaro dange snack bar substitute purple sweet potato flour and Moringa (P2) and the group who were given the Tabaro dange snackbar substitution of yellow sweet potato flour and Moringa (P3). The gift starts on the 8th day after the adaptation period. Giving food and drinks ad libitum and giving Tabaro dange is done orally by feeding the rats, with the time of administration every day for 2 weeks.

The following is the treatment for each group. Control group (K0): feeding pellets. Treatment Group

1 (P1): administration of Tabaro dange F0: Sago 44g (40%), grated coconut 42g (38,18%), cassava 6g (5,45%), brown sugar 13g (7,26%) and anchovies 10g (9,09%) per 4 g/day. Treatment group 2 (P2): granting Tabaro dange F2: Sago 40g (36,36%), grated coconut 42g (38,18%), cassava 2g (1,28%), brown sugar 13g (7,26%), anchovy 10g (9,09%), purple sweet potato 4g (3,64%) and Moringa 4g (3,64%) per 4 g/day. Treatment group 3 (P3): administration of Tabaro dange F3: Sago 38g (34,55%), grated coconut 42g (38,18%), cassava 2g (1,28%), brown sugar 13g (7,26%), anchovy 10g (9,09%), yellow sweet potato (1.82%), purple sweet potato 2g (1,82%) and Moringa 6 g (5,45%) per 4 g/day.

Measurements of body weight of rats carried out on day 7 (before intervention), day k-14 and day 21 after the intervention was given using a digital scale with a level of accuracy of 0,01 kg. Measurement of hemoglobin levels was carried out by the Cyanmethaemoglobin method by taking blood through the rat's tail. Reference to normal Hb levels in mice following physiological values in male rats, which is 13,2-16,4 g/dL.[1] Data were processed statistically using SPSS 24 with data analysis using repeated measures for body weight and kruskall-wallis for Hb data.

Results

Efficacy of Tabaro dange on Weight Loss in White Rats (Rattus norvegicus): Preliminary weight data of rats is weight data before treatment and weight data after treatment is data for the 7th day and 14th day, weighed using a cannary scale digital scale in grams. Data on the average weight gain of white rats (rattus norvegicus) before and after treatment can be seen in Table 1.

Table 1 The average weight of white rat (rattus norvegicus strain wistar) before and after the treatment (grams)

Weight	K0 (Control)	Q1 (F0)	P2 (F2)	Q3 (F3)	p value
Beginning	202,5±8,5	2045±6,7	203,68±6,6	203,5±8,5	0,054
7 days	237,3±44	2386±4,1	239,1±4,9	239,6±4,4	
14 days	257,3±2,8	263,0±1,8	267,6±1,2	275,0±3,03	

The mean weight of all samples before treatment was 203,5±7,1 gram with a weight range between 192-211 grams. The mean weight of all samples of the 7th day after the treatment was 238,7±4,2 gram with a weight range between 232-245 grams. The average weight of the entire sample 14 days after treatment was 265,7±6,9 grams with a range of body weight between 254-281 grams.

Statistical test results showed that there were significant differences between initial body weight, day 7 body weight and day 14 rats (Rattus norvegicus) given the Tabaro dange intervention. Rats' weight gain after day 7 and day 14, respectively, reduced the body weight of rats before treatment. Data on the average weight gain of mice can be presented in table 2.

Table 2: Average weight gain of white rats (Rattus norvegicus) after treatment (grams)

Weight	K0 (Control)	Q1 (F0)	P2 (F2)	Q3 (F3)
7th day	20,0±2,8	27,6±1,7	30,1±1,6	36,3±4,6

Source: Primary Data, 2019

* 233 kcal energy, ** Total Carbohydrates 7-11 g (12-20% of total calories, *** Protein 7,9 g (10-15% of total calories, **** Fat 9,1 g 35% of total calories

The energy content in each tabaro dange formulation has met the emergency food requirements with the highest energy value contained in the F2 formulation of 310,19 kcal. The main source of energy is in carbohydrates, but fats and proteins can also contribute energy through the oxidation process of nutrients.[8] Carbohydrate content in an emergency food product is very important to meet calorie adequacy.[9] In addition to carbohydrates, fat content in emergency foods has an important contribution, namely as one of the energy contributors.[10]

Efficacy of Tabaro dange on Increased Hemoglobin (Hb) White Rat (Rattus norvegicus strain wistar) **Male**

Hemoglobin is a protein that has iron content and plays an important role in transporting oxygen and circulating it throughout the body's tissues.[8] In this study hemoglobin was measured before the intervention was established and after the intervention was given to experimental animals. Data on average hemoglobin levels before and after the intervention are presented in table 4.

Table 4 Average Hemoglobin (Hb) Levels in Experimental Rats

Variable	Group	N	Mean ± SD (g)	Min	Max	P-value
Early Hb	K1	6	8.0667 ± 1.83485	6.40	11.40	0.143
	Q1	6	6.9333 ± 0.48854	6.40	7.50	
	P2	6	7.7333 ± 0.56451	7,10	8.60	
	Q3	6	6.9667 ± 0.37238	6.40	7.40	
Final HB	K1	6	14.3167 ± 1.03618	12,90	15.60	0.001
	Q1	6	15.7000 ± 2.41578	12,20	19.50	
	P2	6	18,0333 ± 1,23882	16.50	19,20	
	Q3	6	23,2333 ± 3,53817	19.40	27.70	
Change in Hb	K1	6	6,2500 ± 2,54617	2.40	9.00	0,000
	Q1	6	8.7667 ± 2.29666	5.80	12.30	
	P2	6	10.3000 ± 0.86487	9.30	11.50	
	Q3	6	16.2667 ± 3.60648	12.30	20.90	

Table 4 shows that the average level of the highest hemoglobin rat (Rattus norvegicus) before the treatment does not have a noticeable difference. ANOVA test results showed that there were significant differences between the initial body weight of rats (Rattus norvegicus) before and after the intervention was given.

Discussion

Weight gain is natural because rats are animals that never stop growing, where the speed of growth will decrease when reaching adulthood.[11] The results showed there were differences in body weight of rats before and after the intervention in the treatment group. One of the factors that increase growth is the intake of food provided in sufficient quantities with the nutritional content contained in these foods.[8] All rats received the same ration, but there were different treatments for the amount of energy contained in the feed. The increase in body weight of mice that received higher F2 compared to other treatments. This is because the Protein content in F2 is higher than other formulas, although the energy content in F2 is lower compared to other formulas, the total energy is sufficient to meet the energy requirements of 10-15% of the AKG.[12] In the phase of protein, growth plays a very important role, because in that phase the process of biosynthesis takes place quickly, especially the formation of body protein, while energy is needed for the ongoing process of the body's metabolism.

Efficacy of Tabaro dange on Increased Hemoglobin (Hb) White Rat (Rattus norvegicus)

Nutrient intake of protein, iron, vitamin A and vitamin C can affect hemoglobin levels. Protein plays an important role in the transportation of iron in the body. Lack of protein intake in the body will be able to lead the transportation of iron deficiency and iron hampered. The lower the protein intake and iron intake, the lower the hemoglobin level.[13]

Vitamin C increases non- heme iron absorption.[14] The presence of vitamin C from Moringa accelerates the absorption of iron in the non-heme form. Iron non-heme by the reduction of ferric iron into Ferro in the small intestine so easily absorbed. The formation of hemosiderin which is difficult to mobilize to free iron can be inhibited by vitamin C. So that it can reduce the risk of iron deficiency anemia.[15]

Vitamin A affects the release of iron from the liver. Supplementation of vitamin A with iron improves vitamin A status and improves iron status.[16] The limitation of this study is that the initial hemoglobin levels were not uniform in all groups of rats to be treated.

The results showed that the administration of local food-based Tabaro dange can increase Hb levels in white rats. The content of protein, iron, vitamin A and vitamin C in Tabaro dange will affect the absorption of globin and iron proteins that can meet the needs of heme. The results of other studies indicate there is a positive relationship between the intake of iron with high levels of hemoglobin.[17]

Conclusion

Local food-based Tabaro dange snacks can increase body weight and hemoglobin levels in male white rats (*Rattus norvegicus*).

SUGGESTION

Further research is needed to determine the acceptability of Tabaro dange snacks so that they can be used as ration products in an emergency.

Abstract

Background: Previous studies indicated that mental health and social relationships have influence on quality of life. However, there are limited studies on the association between mental health and social relationshipson quality of life among Myanmar migrant workers in Thailand.

Method: This study aimed to determine the prevalence of quality of life and the influence of mental health and social relationships on quality of life among Myanmar migrant workers in the South of Thailand.This cross-sectional analytical study was conducted among 794 Myanmar migrants who were selected by using a multi-stage random sampling from 2 provinces in the South of Thailand to respond to a structured questionnaire interview. The generalized linear mixed model analysis was performed to determine the association between mental health and social relationshipson quality of life when controlling other covariates.

Results: The prevalence of good quality of life among Myanmar migrant workers was 11.46% (95%CI:9.24-13.68). Mental health and social relationships were significantly associated with good quality of life were; no had depressive symptoms (adj. OR=3.83; 95%CI: 2.28-6.43, p-value < 0.001), had good relationship with employers (adj. OR=3.02; 95%CI: 1.71-5.31, p-value < 0.001) and had high level of involvement with peers (adj. OR=1.90; 95% CI: 1.09-3.32, p-value < 0.023). Significant covariates were average personal monthly incomes and received health information.About one-tenth of Myanmar migrant workers had a good quality of life. Mental health, social relationships and access to health information had influencedtheir quality of life.

Keywords: *Myanmar migrant workers, Quality of life, Social relationships, Thailand.*

Introduction

Quality of life (QOL) is a multidimensional level of an individual life's happiness where they live in societies to achieve their goal in life. QOL consists of 4 domains including physical, psychological, social relationships and environmental domains[(1)]. The concept of QOL is commonly used to describe the well-being among various susceptible populations, such as migrants, refugees, etc.[(2-4)], since QOL describes the degree to which a person enjoys the important possibilities of his or her life[(5)]. There were a number of factors influencing QOL. Social relationships were one of the factors associated with QOL of which it increased the likelihood of survival[(6)]. A study carried out in the Basque Country, Spain suggested that low social support was related to poor HRQOL, of which identifying the social support is a key in understanding health inequalities among immigrants[(7)].

Migrating to a new country is an extremely complex and stressful process because it involves changes in all areas of life-socially, culturally and psychologically[8]. Psychosocial factors such as lack of social and emotional support from relatives and friends [9] were common among migrant workers. Some studies indicated that migrant workers were refused by local citizens [10] and lack of legal migration status in migration processes [11]. Depression, one of the most common mental health disorders, was identified as having a positiverelationship with occupation injury [12]. Depression imposes an immense social burden which leads to functional impairment, decreased quality of life, low productivity and impaired interpersonal relationship.[13]

Thailand economic growth has attracted an increasing number of migrant workers from neighboring countries [14]. Migrant workers in Thailand are mostly involved in the ''3 Ds'' jobs (dangerous, dirty and degrading jobs). These 3Ds conditions push them at risk for health problems. One notable health hazard of migrant workers is the deterioration of mental health, which has been implicated to suicide that is more common among migrant workers than that of local citizens [15].The Office of Foreign Worker Administration of Thailand reported that in July 2019 there were 2.83 million migrants residing in Thailand and about 1.87 million were from Myanmar. About 358,530 Myanmar migrant workers were in the South region. Most of these migrants worked in themanufacturing sectors, agriculture and animal husbandry,fishery and construction. Therefore, this study aimed to determine the prevalence of quality of life and the influences of mental health and social relationships factors on quality of life among Myanmar migrant workers in the South of Thailand.

Materials and Method

Study design and sampling: This cross-sectional analytical study was conducted in 2018. The populations were Myanmar migrant workers in the South of Thailand. The sample size was calculated by using the formulato estimate the sample size forlogistic regression analysis of Hsieh [16].The estimated sample size was 794. Werecruited Myanmar migrant workers from 2southern provincesby using multi-stage random sampling method.

Questionnaire: A structure questionnaire was developed based on the research questions and relevant literatures. The structured questionnaire consisted of 6 parts: A) Demographic and socioeconomic characteristics, B)Social relationships, C) Health behaviors and physical health status, D) the Perceived Stress Scale (PSS) of Cohen et al. [17], E) The Center for Epidemiology Studies Depression Scale (CES-D)[18], andF) WHOQOL-BREF was used to assess the quality of life. QOL scores were categorized into three groups: a) poor level (26-60scores), b)moderate level (61-95scores), c) good level (≥96scores)[1]. The questionnaire was undergone content validation by 5 experts and revised to improve its validity. The Cronbach's alpha coefficient of PSS, CES-D and WHOQOL-BREF were 0.78, 0.70 and 0.85 respectively.

Statistic Analysis: All analyses were performed using Stata version 10.0 (Stata Corp, College Station, TX). Demographic and socioeconomic characteristics of the participants were described by using frequency and percentage for categorical data as well as the mean and standard deviation for continuous data. A simple logistic regression was used for bivariate analysis to identify individual factor associated with QOL. In the bivariate and multivariable analysis, quality of life was classified into 2 groups using the cutoff score of ≥ 95 points which mean 'hada good quality of life'. The independent factors that had p-value <0.25[19] were processed to the generalized linear mixed model (GLMM) analysis to identify the association between mental health and social relationships with QOL when controlling the effect of other covariates and reported the adjusted odds ratio (Adj. OR),95% confidence interval (CI) and p-value<0.05 as the magnitude of effect and statisticalsignificant level.

Results

Majority of the Myanmar migrant workers were male (58.31%) with the average age of 32.79 (±9.00) years old, 69.52% were married and 37.78% finished only primary education. Most of them lived in urban settings (81.74%),75.19% lived with a family and46.98% lived in a labor camp. The highest proportion worked in manufacturing (29.97%) followed by agriculture and animal husbandry, fishery and construction. Their average personal monthly incomes was 9,201.17(±2,681.29) Baht, of which 3,203.21 (±1,660.17) Baht were average personal monthly expenditures. Almost all had health insurance (99.62%).

Most of the workers worked both indoor and outdoor (64.23%) and the rest (35.77%) worked only indoor. Most of them satisfied with their living and working

conditions as well as the relationship with others, except that 58.56% had a limitation on traveling. About one-third were smokers (38.16%), 16.12% were drinkers. More than half of the migrant workers (54.91%) had a physical check-up and 11.08% had chronic diseases. Most of them (88.66%) had a moderate level of stress and more than half (52.77%) had depressive symptoms.

Concerning the quality of life, 85.77% (95% CI: 83.15-88.03) of the migrant workers had a moderate level, 11.46% (95% CI: 9.42-13.87) had a good level and 2.77% (95% CI:1.82-4.17) had a poor level.

Factor associated with good quality of life: Bivariate analysis: The bivariate analysis results indicated that the independent variables that possibly associated with good QOL (p-value<0.25) were;average personal monthly income, physical health check-up, involvement with peers, relationship with employers, relationship with co-workers, relationship with family, received health information and depressive symptomsThese factors have proceeded to the multivariable analysis (Table 1).

Discussion

The findings observed that most of the Myanmar migrant workers perceived of having a moderate level of QOL (85.77%), only 11.46% having good QOL. It might be that the situations where they lived and worked were as they expected. They were not much better. This study also observed that those who had no depressive symptoms had a significantly better quality of life in comparison with those who had depressive symptoms, of which similar with previous studies conducted in China[20, 21].Besides, those who had a good relationship with employers had a significantly better quality of life in comparison with those who had a poor and average level which was similar with a study conducted in Thailand [22]. It might be that the relationship with peer could result in job security and incomes.The migrant workers who had a high level of peer involvement had significantly better QOL than those who had low to moderate levels of peer involvement which was similar to a study in Sweden[23]. It might be that they could share various issues and able to release their tensions. Concerning personal monthly incomes, this study indicated that those who had average personal monthly incomes≥9,300 Baht were more likely to have good QOL in comparison with those who had lower incomes.A study conducted in China was also observed a similar finding[20]. Concerning health, migrant workers who received health information were more likely to have a better quality of life in comparison with those who had not received health information. Migrants have usually accessed health information through social networks more than formal health service providers due to language and access barriers[24].

Conclusion

About one-tenth of Myanmar migrant workers in the South of Thailand had a good QOL. After adjusting for other covariates which were personal monthly income and access to health information;mental health especially depressive symptoms and social relationships including had a good relationship with employers and high level of peer involvement were found significantly associated with QOL.

Diagnostic and Prognostic Role of Micro RNA 208 in Patients Undergoing Primary Percutaneous Coronary Intervention

Khaled Baraka[1], Adel Hamdy[1], Alaa Rabeaa[1], Lamiaa Hamdy[2], Amany Mostafa[2]

[1]Cardiology Department, [2]Clinical Pathology Department, Faculty of Medicine, Minya University, Minya, Egypt

Abstract

Background: Despite improvements in the treatment of MI, 30% of patients show LV remodeling post-MI, moreover, it is expected that almost 30% will have an LV ejection fraction (LVEF) below 40% at 6 months post MI. the importance of adverse LV remodeling detection highlights in predicting morbidities and mortality in patients with AMI and/or congestive heart failure (CHF). The plasma miR-208a level analyzed by qPCR showed greater sensitivity and specificity in identifying myocardial injury than other miRNAs. Up regulated miR-208a from patients with dilated cardiomyopathy (DCM) was negatively correlated to left ventricular ejection fraction (LVEF). To address these problems, echocardiographic tools including strain and strain-rate provides a new window into myocardial injuries and deformation process, especially after introduction of two-dimensional (2D) speckle-tracking echocardiography which allows angle-independent quantification of myocardial deformities.

Aim of the Work: To evaluate the diagnostic role of micro RNA 208a in acute STEMI and To study the differences in micro RNA 208a expression between patients with LV systolic dysfunction and those without, following primary PCI for acute STEMI

Patients and Method: This study was conducted on 150 subjects divided into 2 groups. Group I was consists of 100 patients with acute myocardial infarction underwent 1ry or rescue PCI. Group II was consists of 50 healthy volunteers. All patients were subjected to full Clinical evaluation; Routine Laboratory Evaluation, Standard 12-lead electrocardiogram (ECG), Two-dimensional, M-mode, Doppler and color Doppler, strain rate and speckle tracking echocardiographic studies within 48 hours of the onset of chest pain and at 6 months follow up, Diagnostic coronary angiography followed by PCI. Blood sample for detection of the relative expression levels of serum miR-208a.

Results: Our results showed that miRNA 208a was significantly higher in patients with acute STEMI than age, sex and risk factor matched healthy volunteers, from the 1st hour after chest pain compared with control group. It also revealed that miRNA 208a expression is 100% sensitive and specific for the diagnosis of acute STEMI, with good correlation with cardiac troponin, this study showed that miRNA 208a can predict cardiac remodeling in 6 months follow up after acute STEMI, our study showed that among different echocardiographic data GLS can predict cardiac remodeling in patients with acute STEMI .

Conclusion: miRNA 208a is good biomarker for MI as it is early expressed in serum of AMI patients from 1st hour after chest pain with good correlation with cardiac troponin, miRNA 208a can be used as a predictor for myocardial remodeling after MI. Global systolic longitudinal strain have an important impact in LV remodeling following AMI.

Introduction

Myocardial infarction remains the first cause of death and disability in developed countries. Infarct size is the single most important predictor of adverse

ventricular remodeling and it is linearly dependent upon the amount of myocardial salvage by reperfusion ("time is muscle").[1] Irreversible ischemic injury begins within 15-20 min after the onset of severe ischemia. Irreversible injury is 80% complete within 3 hours of ischemia.[2] fibrotic changes after MI occurs in the infarct border zone and in the remote uninjured myocardium leads to altered chamber compliance and increased ventricular stiffness thereby compromising cardiac output.[3] The benefit of standard treatment as β-blockade and angiotensin-converting enzyme (ACE) inhibition in the acute phase after AMI and in the chronic phase of consequent development of heart failure due to LV remodeling are widely discussed but significant heterogeneity exists in the pharmacological benefits and prognostic outcomes to individual subjects.[4] The degree of inflammatory response varies according to individual response driven by genetic and epigenetic factors.[1]

MicroRNAs (miRNAs) are small non-coding RNAs ~22 nucleotides in length that function as guide molecules in RNA silencing targeting most protein-coding transcripts. The miR-208 family is composed of miR-208a, miR-208b and miR-499. It was found that miR-208a is exclusively expressed in the heart.[6]

miR-208a was undetectable in plasma from healthy people, non-coronary heart disease (CHD), or CHD people (patient with unstable angina), but it was elevated within 4 h after the onset of symptoms in 100 % of the MI patients while only in 85 % of these patients have a cTnT elevation.[7]

It was found that miR-208a can increase endoglin expression in cardiac myoblasts, Endoglin is a potent mediator of profibrotic effects of angiotensin II on cardiac fibroblasts, These data indicate that endoglin may play an important role in fibrogenesis in cardiac remodeling.[8]

Methodology: The present study was carried out at the cardiology department, faculty of medicine, Minia University and Minia Heart Center, Minia, Egypt. It was carried out in the period from June 2017 to December 2018. This study was conducted on 150 subjects divided into 2 groups. Group I consisted of 100 patients with acute myocardial infarction (MI), Group II consisted of 50 healthy volunteers. Patients with cardiomyopathies, congenital heart disease, atrial fibrillation and severe valvular diseases, Patients planning for CABG and Patients with severe chronic systemic diseases, cancer or severe wasting disorders were excluded.

Full clinical evaluation, Standard 12-lead electrocardiogram (ECG), Laboratory tests; including cardiac biomarkers, Two-dimensional, M-mode, Doppler and color Doppler, strain rate and speckle tracking echocardiographic studies; for group I Echo done within 48 hours of the onset of chest pain and at 6 months follow up, Diagnostic coronary angiography followed by PCI, Blood sample for detection of the relative expression levels of serum micro RNA-208 (miRNA-208) using real-time quantitative reverse transcription polymerase chain reaction (RT-qPCR). The timing of blood collection for the miRNAs analysis is within 2h in the emergency room after hospitalization[9]. The AMI patients were clinically diagnosed as the 3rd Universal Definition of Myocardial Infarction[10]. All samples were collected from consenting individuals according to protocols approved by the ethics committee.

As miRNA-208 is presented in two isoforms: miRNA-208a and miRNA-208b, human miR-208a is exclusively expressed in the heart whereas miR-208b is expressed in the heart and skeletal muscle [11], So our tests were carried out to detect miRNA-208a isoform.

Echocardiography: All AMI patients were examined using 2D echocardiography within 48–72 hours after the symptoms of AMI, using Philips IE 33 machine.

Standard 2D and color Doppler data were averaged from at least three consecutive beats. At baseline, 2D echocardiography was used to assess conventional parameters such LV end-systolic volume (LVESV), LV end-diastolic volume (LVEDV), LV ejection fraction (LVEF), wall motion and E/E' ratio. 2D speckle-tracking imaging analysis for evaluation of deformation parameters (global longitudinal strain) was also performed.

At six-month follow-up, 2D echocardiography was repeated to reassess all echocardiographic parameters. LV remodeling was defined as a ≥20% increase in LV end-diastolic volume (LVEDV) at six-month follow-up compared with the baseline.

Results

Study design, patient characteristics: A total of 100 AMI patients were enrolled for the study. The gender ratio was 85:15 (male: female). Another 50 healthy volunteers were recruited to provide a direct comparison of miRNA levels with AMI patients

There were no significant differences between the two groups regarding various clinical characteristics of patient group. (table 1)

Relative expression of miRNA 208a level was significantly higher in patients with AMI (165.91±17.57) than healthy controls (14.38±2.17), p <0.001 with cutoff value of 77 for miRNA 208a expression, is 100% sensitive and specific for the diagnosis of acute STEMI. (fig 1).

miRNA 208a was found to be expressed early in the plasma of patients with acute STEMI from the 1st hour after chest pain, earlier than cTnT.

Spearman's correlation coefficient was done to find the Correlation between miRNA 208a expression and cardiac troponins and showed a strong positive correlation; r: 0.886.

At follow-up, 39 patients (39%) were classified as having LV remodeling. miRNA 208a level was significantly higher in patients with LV remodeling (170.05±16.61) than in patients without LV remodeling (159.91±15.25), p-value 0.003.

In patient with no LV remodeling there was no significant difference as regard E.F, EDV, ESV at admission and sex months follow up but there was significant difference in GLS. On the other hand patients with LV remodeling show significant difference in LVEF, EDV, ESV but not GLS which is impaired all through after MI. (table 2)

Our results showed that LVESV, E.F and GLS, were all independent predictors of LV remodeling; the most powerful of which was GLS (p: .016, odds ratio 1.180) with cut off value of -10.5 GLS has a sensitivity of 79.5% and a specificity of 64.8 % for the prediction of LV remodeling with area under the curve 0.742.(fig 2)

Similarly miRNA 208a level, LVESV and E.F were all independent predictors of LV remodeling, the most powerful of which was miRNA 208a level (p: 0.001 and odds ratio 1.074), miRNA 208a has 64.1% sensitivity and 63% specificity for prediction of LV remodeling with cut-off value of 162.5 and area under the curve of 0.692.(fig 3).

Discussion

As AMI is among the most important causes of death and illness, so early diagnosis is essential to maximize the effects of cardiac revascularization therapy, there is still a need for new biomarkers that are able to reduce time between the onset of MI and the actual therapeutic interventions. (7)

In this study we investigate the diagnostic and prognostic role of miRNA 208a in patients with AMI. We used RT-qPCR to determine the level of expression of miRNA 208a in 100 patients admitted with AMI and it was found that it was significantly higher in those patients than healthy volunteers and when we used fold change to express the difference between patients and control group it was (11.76±2.16) higher in patient than control group.

In our study miRNA 208a expression is 100% sensitive and specific for the diagnosis of acute STEMI.

miRNA 208a level was significantly higher in patients with LV remodeling than patients without LV remodeling with good correlations to cTnT high sensitive test, which is currently one of the main routine assays used to detect MI events.

LVEF has limitations for risk stratification after MI. To overcome these limitations, we used strain imaging modalities where strain measurement may reflect both the regional (infarct zone) and the global average myocardial deformation quantified by a software algorithm and seems to be more sensitive measurement of LV function.

Our study showed significant differences in GLS between LV remodeling group and non LV remodeling group and showed that the most powerful factor that can predict LV remodeling was GLS. Our study showed that the most powerful factor that can predict LV remodeling was miRNA 208a level.

Our results was concordant with other studies, in one study plasma miR-208a allow detecting acute MI with 90.9% sensitivity at 100% specificity, the best value compared with other cardiac miRNAs. This makes miR-208a as a profound diagnostic marker for earliest acute MI diagnosis. In addition, miR-208a is superior to cardiac troponin in specific diagnosis of acute MI in patients with kidney damage since heart troponins are excreted by kidney and their levels are frequently increased in subjects with chronic renal failure.(12)

Our results showed that miRNA 208a had good correlation with plasma troponin and this was consistent with other studies.(13)

Zaliaduonyte et al in 2014 suggest that LV remodeling was associated with more extensive inflammation process following AMI, this was concordant with our results that shows higher leukocyte count at admission in patients with LV remodeling than those without.(4)

Previous repeated studies showed that the major determinants of ventricular remodeling following AMI are the infarct size and the infarcted artery, enzymatic markers.(14), Results of our study do not contradict these data.

In Park et al. research, patients who showed significant LV remodeling during the follow-up had a significantly lower baseline strain and longitudinal strain >−10.2% was a strong independent predictor of LV remodeling. Differently from the Park study, we have enrolled patients with both anterior and inferior wall MI and our data also show a significant impact of longitudinal strain on LV remodeling prediction.(15)

Our findings was concordant with Zaliaduonyte et al. who enrolled patients with both anterior and inferior wall MI and data show a significant impact of longitudinal strain on LV remodeling prediction.(16)

Chistiakov et al mentioned that Overexpression of miR-208a in cardiomyocytes leads to abnormalities in cardiac rhythm and fibrosis.(12), this was concordant with our results that showed significant elevation of serum miRMA 208a in patients with LV remodeling.

Conclusions

miRNA 208a is good biomarker for MI as it is early expressed in serum of AMI patients from 1st hour after chest pain with good correlation with cardiac troponin, miRNA 208a can be used as a predictor for myocardial remodeling after MI. impaired LV function and reduced global systolic longitudinal strain have an important impact in LV remodeling following AMI.

Limitations: The main limitation of our study was a relatively small sample size, Relatively expensive miRNA extraction and detection kits, some bias in strain evaluation because of image quality inaccuracy may be present.

The Institutional Ethics Committee approved this

study of the School of Medicine, Minia University, Egypt and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

Abstract

Gingivitis is a process of inflammation of the periodontal tissue which is confined to the gingiva characterized by hiperemi, swelling, tendency to bleeding in the gingiva. Local causes include plaque deposits and calculus. initial therapy aims to prevent more severe periodontal inflammation. Research purposes to determine the effect of initial therapy on TGF-β1 protein levels in GCF in patients with chronic gingivitis. The type of research was observational analytic on TGF- β1 protein levels in chronic gingivitis patients, carried out on 10 samples that were controlled 2 times after initial treatment in the form of scaling and root planning in patients with chronic gingivitis.

Research Result: The average level of TGF- β1 protein during pre-therapy was 1081.55 pg/ml, when observation 1 decreased by 599.67 pg/ml and when the second observation increased 957.12 pg/ml, the results of the paired T test obtained a value of $p < 0.05$.

Conclusion: Decreased levels of TGF- β1 protein in GCF of chronic gingivitis patients after initial therapy for severe gingivitis.

Keyword: *Chronic gingivitis, initial therapy, GCF, TGF-β1.*

Introduction

Periodontal tissue is a teeth supporting tissue, consists of gingiva, cementum, periodontal ligament and alveolar bone. Abnormalities could be occured in this tissue due to interaction of host factors, microbes and environment such as gingivitis. Gingivitis is an inflammation of the gingival tissue.[1]

According to data from National Basic Health Research Indonesia (RISKESDAS) in 2013, the national prevalence of dental and oral problems in Indonesia is 25.9%, as many as 14 provinces have a prevalence of dental and oral problems above the national level.[2]

Periodontal disease is an inflammatory process that involves the progressive, episodic loss of the periodontal attachment apparatus, which in turn causes tooth loss in vulnerable patients. Based on data from the National Health and Nutrition Examination Survey III (NHANES III) in 1999-2004, Eke and Barker estimated that the prevalence of moderate and severe periodontal disease was less than 1% in the age group below 35%, with increased prevalence in elder age groups. At the age of 75 years or older, it is estimated that the prevalence in the United States is approximately 18% for moderate periodontitis and 7% for severe periodontitis.[3]

Gingivitis occurs due to inadequate oral health which is usually characterized by redness, swelling and

Corresponding Author:
Dr. Lilies Anggarwati Astuti, DDS
Department of Periodontology, Faculty of Dentistry, University of Muslim Indonesia, Pajonga Dg Ngalle St No. 27, Makassar,Indonesia
e-mail: liliesanggarwati.astuti@umi.ac.id

a tendency to bleeding in the gingiva. The local causes including the occurrence of gingivitis such as plaque and calculus deposits on the tooth surface, impacted food, cavities and inappropriate fillings.[4]

In Indonesia, gingivitis were in second rank, reaching 96.58%. In children, gingivitis does not occur as severely as adult gingivitis. Bacterial plaques in children usually consist of pathogens with low concentration. However, if gingivitis in children is left without good and correct treatment, it can cause periodontitis.[4]

Periodontal disease is multifactorial. When microbial factors and other environmental factors are believed to start and modulate the development of periodontal disease. Genetic and technological information that is needed to predict, diagnose and treat periodontal disease conceptually interesting to explore. Some important components such as cytokines, cell receptors, chemokines, enzymes and others are related to the introduction of antigens, immune systems, host responses. Among others, it is determined by the genetic component where polymorphism is likely to increase an individual's susceptibility to periodontal disease. Gene identification and polymorphism can produce new diagnostics for risk checking, early detection of disease and individual treatment approaches. Thus, genetic epidemiology, include knowledge about genetic polymorphisms can be very promising as a tool that can contribute to the understanding of the pathogenesis of periodontal disease.[5]

This study is considered necessary because every disease in the periodontal tissue, initial therapy is carried out, namely scaling and root planing. This treatment is included in the initial therapy phase. The main goal of early treatment for gingivitis is to prevent more severe inflammation in periodontal tissues so that the prevalence and incidence of periodontitis is reduced. One of the cellular component such as monocytes in the Gingival Crevicular Fluid (GCF) is TGF-β1. In previous studies cellular components molecularly have not been widely studied, especially in gingivitis. The cellular component of TGF-β1 in gingivitis plays a role in balancing the pro-inflammatory and anti-inflammatory cellular components to help the tissue healing process. Analysis of the TGF-β1 gene cytokine in the GCF also needs to be studied in the process of tissue healing after SRP treatment so that it can be used as a marker of gingivitis severity.

Based on this description, the authors are interested in conducting a study on "The Effects of Initial Therapy on TGF-β1 Protein Levels in Gingival Crevicular Fluid (GCF) of Chronic Gingivitis Patients "

Materials and Method

The research was conducted at the Laboratory of Molecular Biology and Immunology and the Microbiology Laboratory of the Faculty of Medicine, Hasanuddin University. This type of research was observational analytic with a pre-test and post-test, prospective cohort study design.

The study population was all patients who wished to have their teeth examined and treated at the AG Dental Care Clinic in South Sulawesi, Indonesia with gingival inflammation and diagnosed with chronic gingivitis that in accordance with the inclusion criteria. The sampling technique used was purposive sampling and number of samples determination was based on the Wilcoxon Signed Rank Test table as many as 10 samples prior to treatment conducted by a single cohort, there was no comparison (prospective cohort observation).

Gingival status is measured using the gingival index:

Score 0: normal gingiva (no inflammation, no discoloration and no inflammation)

Score 1: Mild inflammation (there is a slight change in color and a little edema but no bleeding on probing)

Score 2: Moderate inflammation (redness, edema and bleeding on probing)

Score 3: Severe inflammation (bright red or bright red, edema, ulceration, tendency for spontaneous bleeding).

All dental scores are summed and divided by the number of examined teeth, a person's gingival index score will be obtained.

Criteria for gingival assessment:

Healthy	: 0
Mild inflammation	: 0.1-1.0
Moderate inflammation	: 1.1-2.0
Severe inflammation	: 2.1-3.0

Examination of the gingival index is done by whether there is bleeding or not in the examined teeth, ie in teeth 16, 11,26 and 46,31,36.

Data collection was done by taking patient's gingival crevicular fluid (GCF) before initial therapy and having the first control after initial treatment such as scaling and root planing on day 7 and second control on day 21 and then examining TGF-β1 gene expression, TGF-β1levels and examination of bacteria found on plaques in the molecular biology laboratory, immunology and microbiology of the Faculty of Medicine, Unhas, Makassar. GCF was taken in the gingival sulcus area using a paper point to examine TGF-β1 protein levels (ELISA technique).

Results

Table 1: Description and Test for Normality of expression of TGF-β1 protein levels

	N	Mean ± SD	P
Pre-therapy	10	1081.5 5±44.98	0.908
Observation 1		599.67±65.30	0.458
Observation 2		957.12±151.85	0.412

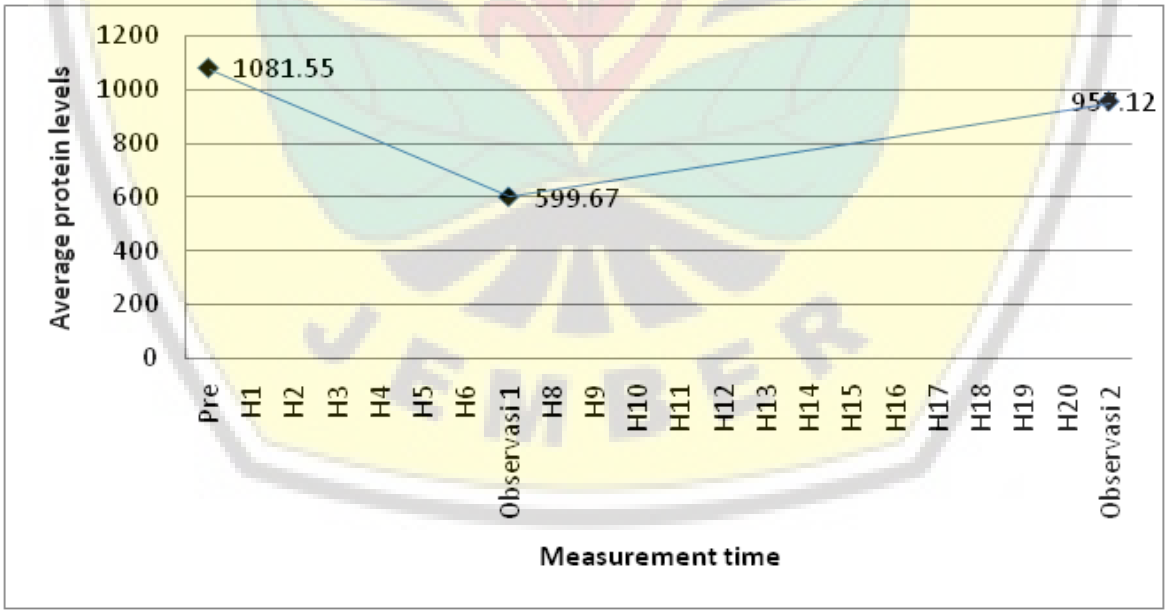
Source: Primary Data

Table 1 shows the average of TGF-β1 protein level at pre-therapy was 1081.55 pg/ml, when observation 1 decreased by 599.67 pg/ml and at observation 2 it increased to 957.12 pg/ml. The results of the Shapiro-Wilk statistical test show that the p value of each data group is> 0.05. These results indicate that the distribution of data is normally distributed, so that Paired T Test can be carried out.

Table 2: The effect of giving initial therapy is scaling and root planing on TGF-β1 protein levels in patients with chronic gingivitis

Paired T Test	n	Mean Differences	P
Pretherapy–Observation 1	10	481,88	0,000
Pretherapy–Observation 2		124.43	0.027
Observation 1–Observation 2		357.45	0,000

Table 2 shows the results of the paired t test obtained p value <0.05, which means that there is an effect of initial therapy given in the form of scaling and root planing to decrease TGF-β1 protein levels in patients with chronic gingivitis. Fluctuations in changes of protein levels of TGF-β1 gene mRNA expression can be seen in the following figure:



Graph 1: Average TGF-β1 protein levels

Discussion

There is also the effect of initial therapy given in the form of scaling and root planing on TGF-β1 protein levels in chronic gingivitis patients with average TGF-β1 protein level at pre-therapy was 1081.55 pg/ml, while observation 1 decreased by 599.67 pg/ml and when observation 2 increased to 957.12 pg/ml. The results of paired t test obtained p value <0.05, which means that

there was the effect of initial therapy given in the form of scaling and root planing on the decreased of TGF-β1 protein levels in patients with chronic gingivitis.

In humans, TGF-β1 levels vary between 49 and 868.6 ng/ml and correlate with probing depth. High TGF-β1 levels (73-1076 ng/ml) were detected in GCF samples from beagle dogs with experimental periodontitis. The second study found that TGF-β1 levels in gingivitis patients (395.4 pg/sample; 899.2 ng/ml) were higher than those seen in healthy controls (303.7 pg/sample; 2634 ng/ml) while theyhad lower concentrations. Buduneli et al., who found TGF-β1 levels in the healthy control GCF were 177 times higher than those reported in this study. TGF-β1 levels in GCF of healthy samples using ELISA range in 0.3-2.4 pg samples and 2-18.2 ng/ml and 0-2.8 pg samples and 0-6.8 ng/ml using those reported for control samples in this study. The results showed that TGF-β1 levels increased at the beginning of the inflammation process (day 7).[6]

This study is in line with the research conducted by Shaimaa et al in 2015 which proved a significant increase in TGF-β1 in the chronic periodontitis group. Similar findings were recorded in a study conducted by Sattari et al. and Vikram et al., who measured TGF-β1 levels in GCF of patients with chronic periodontitis before and after treatment, then showed that TGF-β1 levels were reduced after surgery.[7]

This study is in line with a study conducted by Sidney H. Stein in 2004 reported that the average of TGF-β1 level in GCF was higher in smokers compared to nonsmokers (P <0.03). (Stein, Sidney H, 2004) This study is in line with the research conducted by Alpagot, the average of TGF-β1 from heavy smokers was significantly higher than the average of TGF-β1 in moderate smokers (P <0.0037) and pack year correlated positively with TGF-β1, probing depth, attachment loss and viral load at baseline and 6-month visits (P <0.001). Smoking correlated negatively with CD4 cell count at baseline and 6-month visit (P <0.001). [8]

The results of this study is in line with research conducted by Ali Gurkan in 2005 showing that TGF-β1 levels were seen to be higher in gingival tissue and GCF in the inflammatory area when compared to healthy areas. In this study, it was shown that all groups had almost the same total TGF-β1 GCF at the baseline. With consideration there were anti-inflammatory role of TGF-β1, then a very high cytokine levels can be expected due to the collected sampling area is severe and inflamed areas. Therefore, it can be hypothesized that the collected GCF samples of studied group from the areaswith active disease in which there is an imbalance between anti-inflammatory and destructive factor. However, when the data is expressed as the concentration, the healthy group had higher TGF-β1 GCF levels compared with the placebo group and SDD (subantimicrobial dose doxycycline).Results from the study indicate that SDD supportive therapy improves clinical parameters and increases TGF-β1 GCF levels in patients with severe,generalized chronic periodontitis. The beneficial effects of SDD can be obtained after the end of treatment.[9]

This research supported the research conducted by Lilies AA*et al* concluded that the RT-PCR examination using TGF-β1 primary Macrogen to found TGF-β1 gene expression with results before gingivectomy and SRP treatment of 9.72121. A week after gingivectomy and SRP treatment decreased to 4.10328, three weeks after gingivectomy and SRP treatment rebound to 9,7010. The expression of the TGF-β gene decresed on the seventh day after gingivectomy and SRP treatment and increased again on the 21st day and the TGF-β1 gene here acted as an anti-inflammatory.[10]

Conclusions and Suggestions

Conclusion: There were decrease in TGF-β1 protein levels in GCF of chronic gingivitis patients after initial therapy for severe gingivitis.

Suggestion:

As for suggestions for further research, such as:

1. It is necessary to examine other cytokines such as IL5, IL8 and IL11 which play a role in the pathogenesis of gingivitis.
2. Examination of the TGF-β1 gene mRNA is needed for curettage treatment in the gingival pocket of gingivitis cases.
3. Examination of TGF-β1 protein levels is needed for curettage treatment in the gingival pocket of gingivitis cases.
4. Comparison of other gingivitis cases is needed so that some predisposing genetic factors that causes gingivitis can be obtained.
5. Comparison of healthy gingival samples is needed so that the normal values contained in the GCF are

obtained.

6. Variation of treatment given for sample is needed such as conventional medicine or herbal extracts that have been tested in humans.
7. More samples are needed to see the polymorphism of gingivitis.

Conflict of Interest: The authors declare that they have no conflicts of interest.

Sexuality Awareness of Women During Pregnancy

Lucia Mazúchová[1], Barbora Ďuríčeková[1], Simona Kelčíková[1]

[1]Comenius University, Jessenius Faculty of Medicine in Martin, Department of Midwifery, Malá Hora 5, Martin 036 01, Slovakia

Abstract

The aim of the study was to find out the women's sexuality awareness during pregnancy. *The research was designed as a quantitative cross-sectional study.* To collect the relevant data, a self-constructed questionnaire was developed. The participants were 242 pregnant women in an average age 28.07 ± 5.13 years. The results were evaluated using descriptive statistics and the chi-squared test. Most women (61.98%) have expressed awareness of sexuality during pregnancy, but only 40.08% have provided sufficient information when determining the level of awareness, which has also been shown in their knowledge. There was no statistical significance between parity and awareness. Primary healthcare education (by gynecologists, midwives), which has proven desirable and inadequate, needs to be strengthened and enhanced. Proper awareness can contribute to a better quality of life for pregnant women, which also includes the sphere of sexuality.

Keywords: *Sexuality, Pregnancy, Pregnant women, Awareness, Midwife.*

Introduction

Sexuality is an integral part of the individual as well as the whole, formed by the close connection of its biological, psychological and socio-cultural dimensions. Sexuality is an important part of the health, but also of one's general well-being[1]. Pregnancy is a period that requires management of important life events such as physical and psychosocial changes[2], it calls for new forms of balance with regard to hormonal changes that affect both physical and emotional dimensions. One of the dimensions that can be affected is also sexuality.[3] In some women, the period of pregnancy changes their sexual behaviour; it affects quality of life and their partner coexistence[4,5].

In pregnant women, sexual dysfunction has a high prevalence[6]. The reason may be that this issue is taboo and women's concerns are unnecessarily raised by various irrelevant recommendations and prohibitions. It is assumed that in women with physiological pregnancy, despite changes in their body resulting from the pregnancy process, sexual intercourse is possible for the entire duration of pregnancy without risk to the mother and foetus, as long as hygiene requirements are maintained and woman's desire is a determining factor. [7,8] Adequate sexual activity poses no danger to physiologically active pregnancy. Sexual satisfaction improves the self-esteem of pregnant women, facilitates mutual relationship between partners and strengthens their marriage[9]. Pregnant women need to learn more about this topic, however, in this period, their awareness and support are yet inadequate.[4]

Raising awareness and counselling on sexuality should be a part of the prenatal care, in order to help couples maintain an intimate relationship and a healthy, positive sexual life[10] and thus improve the quality of care for pregnant women[6].

The aim of the study was to find out the women's sexuality awareness during pregnancy.

Research Methodology

The research was designed as a quantitative cross-sectional study. The research data were collected in five gynaecological outpatient clinics. The research sample consisted of 242 respondents with a mean age of 28.07 years (SD ± 5.13 years). The purposive sampling technique was used in the research. Pre-determined inclusion criteria were a current pregnancy and an informed consent of a participant for the research study. From the point of view of the period of pregnancy by

trimesters, 6.20% were in first trimester, 29.75% in the second trimester and the majority, 64.05% in the third trimester. Within the research sample, 62.81% were the primiparous women, 27.27% were the secundiparous and 9.92% were the multiparous. Most respondents (55.37%) finished the secondary education, 43.80% the higher education and 0.83% primary education (table 1).

To collect the relevant data, a self-constructed questionnaire was developed. It was based on literature survey and focused on the research areas regarding awareness, knowledge, concerns and changes related to sexuality during pregnancy.These research areas were examined in accordance with the variable criteria (age, trimester, parity). However, we present only the partial results of the research study. Statistical functions within MS Excel 2000 and IBM SPSS 22.0 – descriptive statistics and the chi-squared test (X^2) were used for statistical data processing.

The clarity of the questionnaire was verified by a pilot study with 5 pregnant women using a group interview method. Based on the piloting, the problematic formulations of a formal and stylistic character were modified. The study was approved by the Ethical Commission of the Žilina Self-Governing Region. A combined method of administering questionnaires was chosen in five gynaecological outpatient clinics. The choice of the outpatient clinics was determined by their availability and also by the obtained consent of their gynaecologists. Pregnant women attending the prenatal counselling were addressed personally. Once the informed consent was signed, they were instructed how to complete the questionnaire. The questionnaire could be completed in a printed form or electronically via a given e-link, sent to the e-mail addresses of the respondents, if required. The questionnaires were completely the same for both printed and electronic form. 87 questionnaires were distributed personally, reaching 80.5% of responsiveness ($n = 70$) and 200 questionnaires were sent electronically to e-mail addresses, reaching 86.5% of responsiveness ($n = 173$). Total responsiveness was 84% ($n = 287$). The research data collection was conducted between September 2015 and January 2017.

Results

Table 1: Basic characteristic of participants

Characteristic (n=242)	n (%)
Age	
18 – 25years old	78 (32.23%)
26 – 35years old	137 (56.61%)
36 - 45 years old	27 (11.15%)
Education	
University education	106 (43.80%)
Secondary school education	134 (55.37%)
Primary education	2 (0.83%)
Parity	
Primiparous	152 (62.81%)
Secundiparous	66 (27.27%)
Multiparous	24 (9.92%)
Trimester	
1st trimester	15 (6.20%)
2st trimester	72 (29.75%)
3st trimester	155 (64.05%)

Table 2: Level of awareness and parity

	Overall Awareness		Parity						(X^2)	p
			Primiparous		Secundiparous		Multiparous			
	n	%	n	%	n	%	n	%		
Fully sufficient	97	40.08	59	38.81	26	39.39	12	50.00	9.155	0,907
Partially sufficient	79	32.64	46	30.26	24	36.36	9	37.5		
Somewhat insufficient	26	10.74	19	12.5	7	10.60	0	0.,00		
Absolutely insufficient	22	9.09	17	11.18	3	4.55	2	8.33		
I have no information	18	7.43	11	7.23	6	9.09	1	4.17		
Total sample	242	100	152	100	66	100	24	100		

X^2–a chi-squared test; p–significance level ($p<0.05$).

150 (61.98%) respondents reported to have been informed on women's sexuality and intimate relationship during

pregnancy, whereas 92 (38.02%) women expressed to lack the information. Therefore, we further surveyed sufficiency of this information.

40.08% of respondents reported to have received fully sufficient information on this topic and 32.64% stated to be partially informed. 7.43% of pregnant women expressed to have no information and absolutely insufficient information reported 9.09% of surveyed respondents.

Level of awareness and parity: The best awareness of women's sexuality and intimate relationship during pregnancy had multiparous women (overall awareness was in 50.00% respondents fully sufficient, in 37.5% partially sufficient), then the secundiparous (39.39% had fully sufficient information, 36.36% had partially sufficient information) and the least aware of this issue were the primiparous (38.81% had fully sufficient information and 30.26% had partially sufficient information).

The significance level p <0.05 showed no statistical significance (Chi2=9,155; p=0,907) between the parity and the level of sexuality awareness during pregnancy.

In order to verify adequate awareness, we examined women's knowledge of the issue of sexuality during pregnancy.

Table 3: Suitability of sexual intercourse during pregnancy

Answer	n	%
1st trimester	28	11.57
2st trimester	68	28.10
3st trimester	13	5.37
It is not possible during pregnancy	4	1.65
It is possible during the entire pregnancy	129	53.31

Only half of the respondents (53.31%) stated the correct answer that sexual intercourse is possible throughout the entire pregnancy. The second most frequent answer was that the intercourse is acceptable in the second trimester (what said 28.10% of respondents), then in the first trimester (expressed by 11.57% of respondents) and the least common answer was the third trimester (5.37% of respondents). However, there were also women (1.65%), who think the sexual intercourse is not possible during the whole pregnancy.

For further evaluation of knowledge, we asked the women, when is the sexual intercourse unsuitable during pregnancy. In this question, the respondents had the option to mark multiple answers. In total, they marked 973 (100%) answers. The most frequent concerns that women expressed regarding sexual intercourse were fear of preterm labour or miscarriage 225 (23.12%), infection or discharge 201 (20.66%), any kind of genital bleeding 196 (20.14%), cervix dilation 142 (14.59%) and placenta praevia 85 (8.73%). All answers may be considered as correct, however, several respondents marked also incorrect answers as: the last weeks before the labour 42 (4.32%), haemorrhoids 23 (2.36%), gestational diabetes 13 (1.34%), varices 8 (0.82%), anaemia 7 (0.72%). When asked whether it is necessary to use contraceptive method during sexual intercourse, up to 28 (11.57%) respondents stated their consent.

We surveyed whether the pregnant women **are interested in information on sexuality in pregnancy**. Majority of respondents (78.10%) expressed their interest in information on female sexuality and intimate relationship during pregnancy, whereas 21.90% of respondents didn't show their interest.

We also asked about **preferred sources of information** about the issue. In this question, respondents had the option to mark multiple answers. Altogether, they marked 412 (100%) of answers. Most often they wanted to be informed about the issue of sexuality in pregnancy by their gynaecologist 171 (41.50%), information brochure 83 (20.15%), midwife 72 (17.48%) and internet 68 (16.50%).

We were interested in the awareness of the issue of sexuality in pregnancy by gynaecologist/and midwife. 106 (43.80%) respondents were informed about this issue by gynaecologists/midwives and 137 (56.61%) respondents were not informed.

Discussion

In the study, Kouakou et al.[11] indicated that inadequate awareness and prejudice about sexuality in pregnancy have a negative impact on sexual life during pregnancy. Our study brought up that even though the majority of women (61.98%) admitted to be informed on women's sexuality and intimate relationship during pregnancy, it shall not be satisfactory enough for us, as the fully sufficient level of awareness expressed only 40.08% of women. Thus, the majority of respondents were either partially or insufficiently informed about the issue (tab. 2). The best informed about women's

sexuality and intimate relationship during pregnancy were multiparous women, then the secundiparous and the least informed about this issue were the primiparous women, although no statistically significant differences based on parity were demonstrated (tab. 2). Since the knowledge evaluation was of a subjective character, we also focused on the detection and assessment of awareness based on women's knowledge. We can state that in some respondents, the knowledge was inaccurate or distorted. Only half of the women answered correctly that it is possible to have sexual intercourse during the whole duration of pregnancy. Some respondents (1.65%) even thought that it was impossible to have sex in pregnancy at all. Despite the identified lack of knowledge, the findings were still more positive, when compared to another study with shown 18% of women having the same opinion[4]. In 11.57% of women the awareness was significantly low, as they said it was still necessary to use contraceptive method during sexual intercourse in pregnancy. The positive thing is that the majority of women expressed their interest in information on women's sexuality and intimate relationship during pregnancy. As sources of information on this issue the respondents preferred mainly gynaecologist, information brochure, midwife and internet. However, the internet is not always a trustworthy source, as many times the published information come solely from experiences of other women and are not based on professional opinions. According to findings, only 29% of women discusses the sexual issues with their doctors[12]. In our study we found that less than half of women (43.80%) were informed on the topic of sexuality in pregnancy by their gynaecologist/midwife. Revealing the problem of women being insufficiently informed by gynaecologists/ midwives ought to lead to solution and correction. Similar results of insufficient informing on this issue by health professionals (gynaecologists/midwives) were found also in other studies[4, 9, 13]. Authors of these studies emphasize how important is to provide consultations on sexuality in pregnancy by health professionals within the scope of prenatal care services. According to Paulet et al.[14], the discussion on the expected changes in sexuality during pregnancy should be routinely performed by doctors and midwives to improve the perception of sexuality in pregnancy. The health professionals should inform on sexuality each pregnant woman and not only those, who express their interest in this subject matter. Some women, due to their shyness, are unable to talk about this issue or hesitate to ask doctor or midwife for advice or information. The lack of awareness and lack of adequate information on sexuality in pregnancy raises unnecessary concerns about the potential negative obstetric outcomes, leading to prevention of sexual activity during pregnancy[15]. Accurate counselling of partners about sexuality during pregnancy can help to reduce concerns and thereby reduce the high level of female sexual dysfunction[16]. Midwives/nurses need to draw attention to the needs of pregnant women, listen to their concerns, difficulties, identify their knowledge, including the intimate area of sexuality during pregnancy and contribute to their awareness, or at least facilitate their access to the necessary information. Several studies from the various branches of medicine have demonstrated the substantial importance of informative counselling by health professionals[17,18,19].

The above-mentioned results and findings should be considered within the scope of the limitations of our research. In our case, the limitation is presented by a deliberate choice of the respondents and as a result the conclusions can be interpreted only within this selected research sample group. Further limitations of the research could be an uneven structure and composition of the sample group when comparing awareness by parity. As a result, the presented research study can be considered as only partial and might serve as a starting point for another, more extensive research on this subject. Despite these limitations, we believe that our research study has brought some constructive and challenging results.

Conclusion

In our work we wanted to point out the importance of informing women about the issue of sexuality during pregnancy. We found that most women subjectively felt informed about the issue, but the level of this information was not sufficient and the knowledge resulting from the information was distorted and inaccurate. We see the contribution of our work in revealing the need to improve awareness of this issue and to increase and enhance the education of women about sexuality during pregnancy in primary healthcare by trustworthy healthcare professionals. Midwives should be the main source of information and thus contribute to the health-related quality of life of pregnant women, including their sexual life during pregnancy.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: The study was approved by the Ethical Commission of the Žilina Self-Governing Region (Slovak Republic). All participants received full information about the nature and goals of the research, as well as about the details connected with their involvement in the study. The data collection was anonymous and all participants expressed their willingness to be included in the study, attaching their informed consent.

Barriers in Utilization of Public Health Services by Elderly Slum Dwellers in Jaipur City

Mamta Chauhan[1], Sanjaya Saxena[2]

[1]Associate Professor, [2]Registrar, State Institute of Health and Family Welfare, Rajasthan, Jaipur, India

Abstract

Background: Slum population in India is increasing with urbanization and even after various efforts of Government and NGOs, slum dwellers remains deprived of basic services for quality of life. Getting health services by elderly slum dwellers is also a challenging task.

Objective: The aim of this study was to find out the major barrier perceived by elderly slum dwellers in utilization of Health services. Methodology*:* 125 elderly aged 60 and above were randomly selected from Jawahar Nagar Urban slum of Jaipur, Rajasthan. Structured interview schedules were developed, field tested and used to interview elderly slum dwellers. Result*:* 84% of the elderly respondents were aware of the nearby government health facilities; data indicates that unaware elderly did not access any public health care facility. unawareness is a barrier in accessibility of health services. 78.26 percent elderly were aware about the free treatment facility available at government health centers but unaware elderly have not accessed any public health care facility. It was found that maximum waiting time of more than 60 minutes was for those who visited public hospital. 77.6% elderly did not have free health care card mostly due to unawareness. Other barriers to access of health care were Behavior of service providers (88.3%), Distance from home (64.7%), Transport facility (82.4%), Amenities at the health facility (88.3%) and Convenience for attendants (88.3%).Conclusions*: Major barrier identified by elderly slum dwellers in utilization of Health services are* Availability of service provider, cost, timeliness, ease of access, behavior of service provider and coverage through insurance or beneficiary schemes.

Keywords: *Utilization, Barrier, Health Services, Slum dwellers.*

Introduction

The well-being of senior citizens (Old age population as defined by WHO is - population aged 60 years and above) is mandated in the Constitution of India under Article 41- "The state shall, within the limits of its economic capacity and development, make effective provision for securing the right to public assistance in cases of old age". Item No. 9 of the State List and item 20, 23 and 24 of Concurrent List relates to old age pension, social security and social insurance and economic and social planning[1].

India is in a phase of demographic transition. There has been a sharp increase in the number of elderly persons between 1991 and 2001. It has been projected that by the year 2050, the number of elderly people would rise to about 324 million. India has thus acquired the label of "an ageing nation". The elderly as per the 2001 census were 7, 66, 22,321 i.e. 7.5% of total population; out of which aged males were 37, 768, 327 i.e. 7.1% of total population and the aged females were 38, 853, 994 i.e. 7.8% of total population[2]. One of the main social effects of extension of life in later years is the extended period of widowhood for women (Ingle GK, Nath A).[3]

WHO (2004)[4] reported that despite the critical role that PHC centers play in older persons' health and well-being, older people encounter many barriers to care such as the unavailability or expensive transportation, waiting in long line in uncomfortable settings, becoming discouraged from seeking and continuing treatment and so on. Barriers to accessibility may be assessed on following parameters: Availability of health services

Cost of care, Timeliness and easy initiation of services, Behavior of service providers and Insurance coverage/ free health care schemes. This study is an overview of the situation and perception of elderly slum dwellers on barriers in accessing health services.

Methodology

Study Design:

- This was a Cross sectional study
- The Unit of study was an elderly slum dweller

Study Area:

- Jawahar Nagar Urban slum (JNUS), Jaipur city

Study Population: There are around 65000[4] slum dwellers in Jawahar Nagar Urban Slum (JNUS) of which 7.5% are in the age group of 60 and above. So there should be around 4875 old people. However, over 80% families are nuclear thus the older population in JNUS is around 975 approximately.

Sample size and technique: There are 7 sectors in JNUS. Out of these 7 sites approximately 15-16 elderly from each site were selected (Total 125) using a method similar to snowball technique and with the help of local social workers.

Data Collection: Data collection was done through using a pretested interview schedule and started from 10th April till 3rd May 2012.

Tools:

- Interview schedules
- Semi-structured interview schedules
- Facilitator guide for FGD

Data Analysis: Data collected through interview schedules was analyzed with SPSS computer software. The Findings of FGD were related with the finding from the analysis of quantitative data.

Results

73.6%respondents were in the age group of 60-70 and 20.8%. were in the age group of 71-80. Only 1.6% of the respondents were in the age group of 91-100. The respondents were randomly selected among the elderly population in the study area. Females outnumbered males with 56.8% as compared to males with only 43.2%. All respondents were married, however 28.8% of women were widow (51% of total women respondents). It was found that 78.4% of the respondents were illiterate and 12.0% have done school education up to primary level whereas just 0.8% have done up to senior secondary level. So far as the occupation of the elderly slum population is concerned, it was found that majority of them, about 54.4%, were dependent on others as they have 'no work' for them followed by 21.6% daily labourers. Only 8.0% were retired government employees. Also 4.8% of respondents were found to be beggars.

Awareness about nearby public health facilities: It is on the assumption that awareness about public health facility nearby would affect utilization of health services. In this study, it is found that about 84% of the elderly respondents were aware of the nearby government health facilities (Fig. 1).

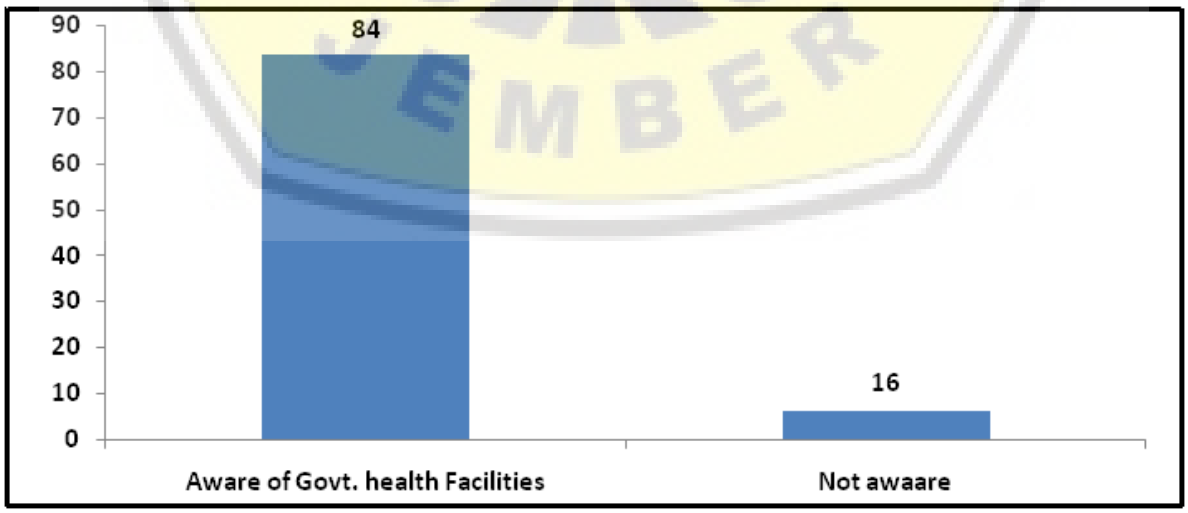

Fig. 1: Percent of Elderly Slum Dwellers According to Awareness of the Nearby Government Health Facility (n=125)

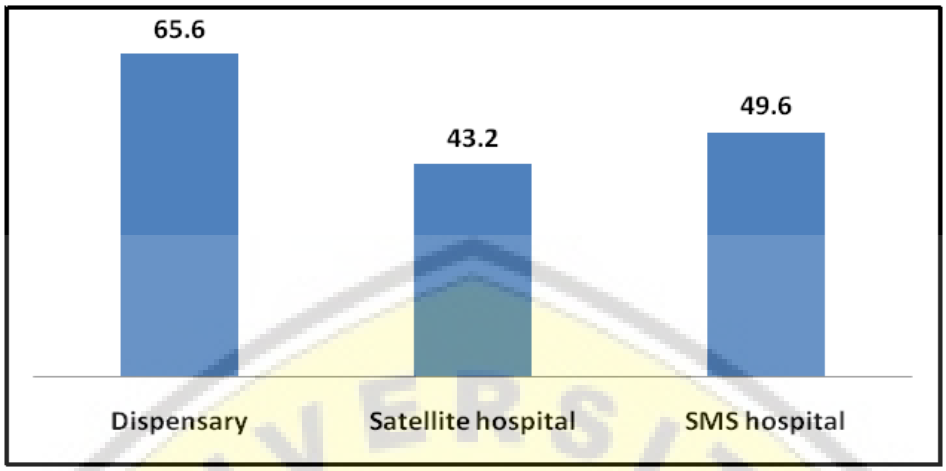
The awareness about various type of nearby government health facilities was also assessed. It is found that 65.6% were aware of Dispensary, followed by 49.6% for SMS Hospital and only 43.2% were aware of Satellite Hospital (Figure 2).



*Multiple responses hence sum of percentage is not equal to 100

Figure 2: Percentage of Elderly Slum Dwellers according to Awareness about Type of Govt. Health Facilities (n=115)*

The table 1 indicates that unaware elderly have not accessed any public health care facility. Thus it is evident that unawareness is a barrier in accessibility of health services.

Table 1: Percentage of Utilization of Various Health Facilities by Unaware Elderly Slum Dwellers (n=20)*

Type of facility	Minor illness	Major Illness	Emergency
Public	0	0	0
Pvt. Hospital	50.0	83.3	75.0
Pvt. clinic	41.7	16.7	8.3
UMP	25.0	00	00
Chemist shop	41.7	00	00
Call doctor at home	8.3	8.3	8.3

*Multiple responses hence sum of percentage is not equal to 100

Awareness about 108 ambulance and free treatment services: 108 ambulance services are considered to be very popular in Rajasthan in providing transportation to the consumers during emergency health situations. We tried to capture opinion of the elderly slum dwellers about the utility of these services. We found only 52.17% elderly aware of the 108 ambulance services (Table 2). However, this doesn't mean that their family members are also not aware of such a service, yet the utilization rate of 108 ambulance services explains the reason behind low level of awareness. The utilization of 108 ambulance services was found to be zero among the elderly slum dwellers. Because of zero utilization rate even by those who were aware, rest of them hardly need to be aware of these services.

Table 2: Percent of Elderly Slum Dwellers According to Awareness & Utilization of 108 Ambulance Services

108 Services	Percent (n=115)
Aware about 108 services	52.17
Not aware about 108 services	47.83
Utilizing 108 services	Nil

Awareness about free treatment at public health facility: We also tried to gather their opinion about free treatment services available at the government health facilities. It can be seen from the figure 3 below that 78.26% elderly were aware about the free treatment facility available at government health centers. This

could be due to low education level among the elderly slum dwellers. Besides, this could also be due to low utilization of government health facilities.

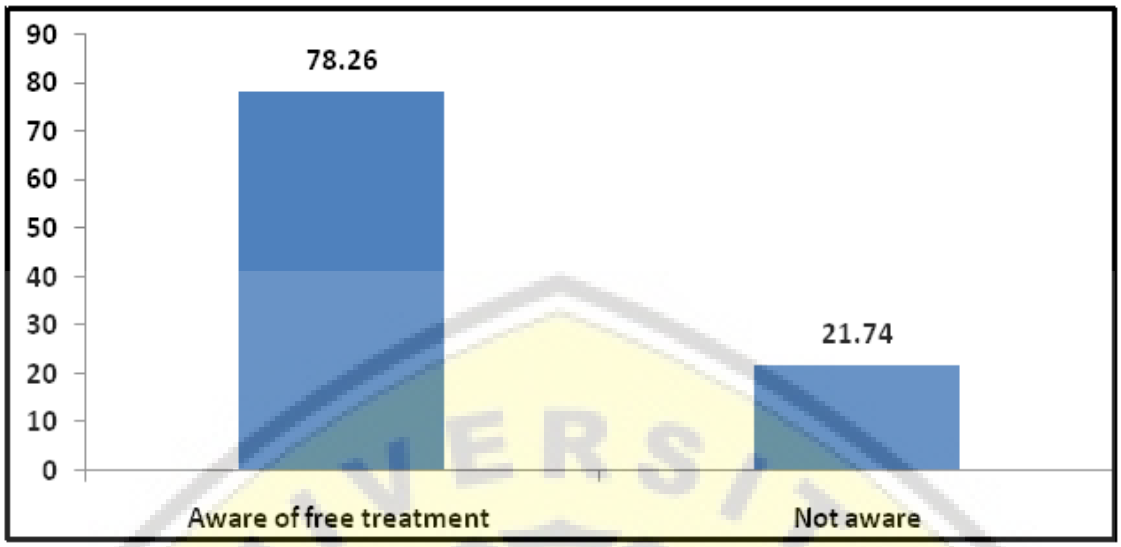


Fig. 3: Percent of Elderly Slum Dwellers according to Awareness about Free Treatment at Government Health Facilities (n=115)

Waiting Time: The waiting time at the health facility is an important determinant of health care accessibility. People prefer to go to a facility where waiting time is less unless the desired services are exclusively available at a certain facility. The average waiting time taken in the hospitals is given below in the figure 4.

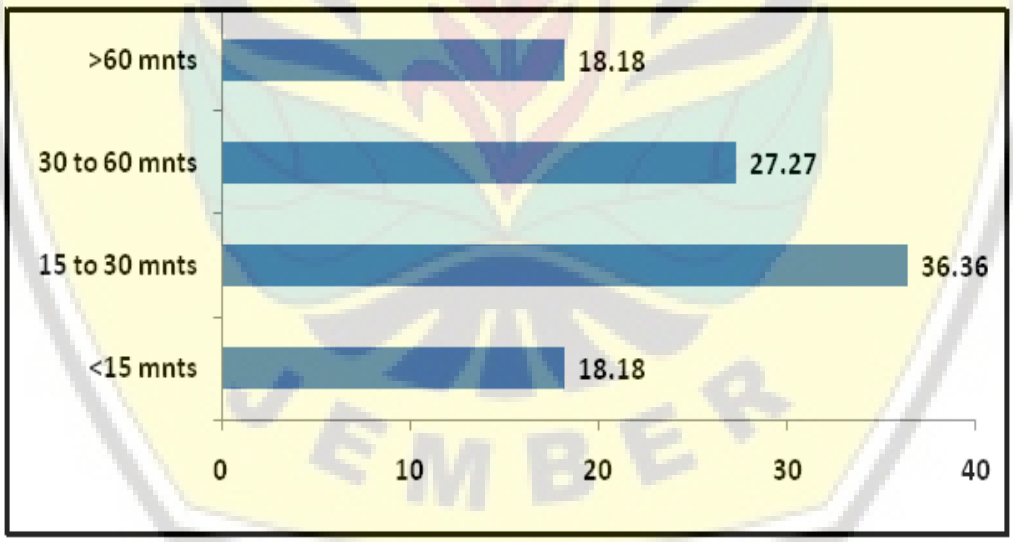

Fig. 4: Percent Waiting time at hospital (n=22)

Table 3: Percent of Elderly Slum Dwellers According to Waiting time by Type of Facility (n=32)

Waiting time	Public (n=15)	Private (n=17)
<15 minute	6.7	17.6
15 − 30 minute	20.0	35.3
15 − 30 minute	33.3	17.6
>60 minute	26.7	0.0
No idea	13.3	29.4
Total	100	100

When we sorted out the waiting time for those who went to any hospital we found that out of 4 treatment seekers, for 3 elderly who visited the private hospital, the time taken was less than 15 minutes. Similarly, it was found that maximum waiting time of more than 60 minutes was for those who visited public hospital (Table 3).

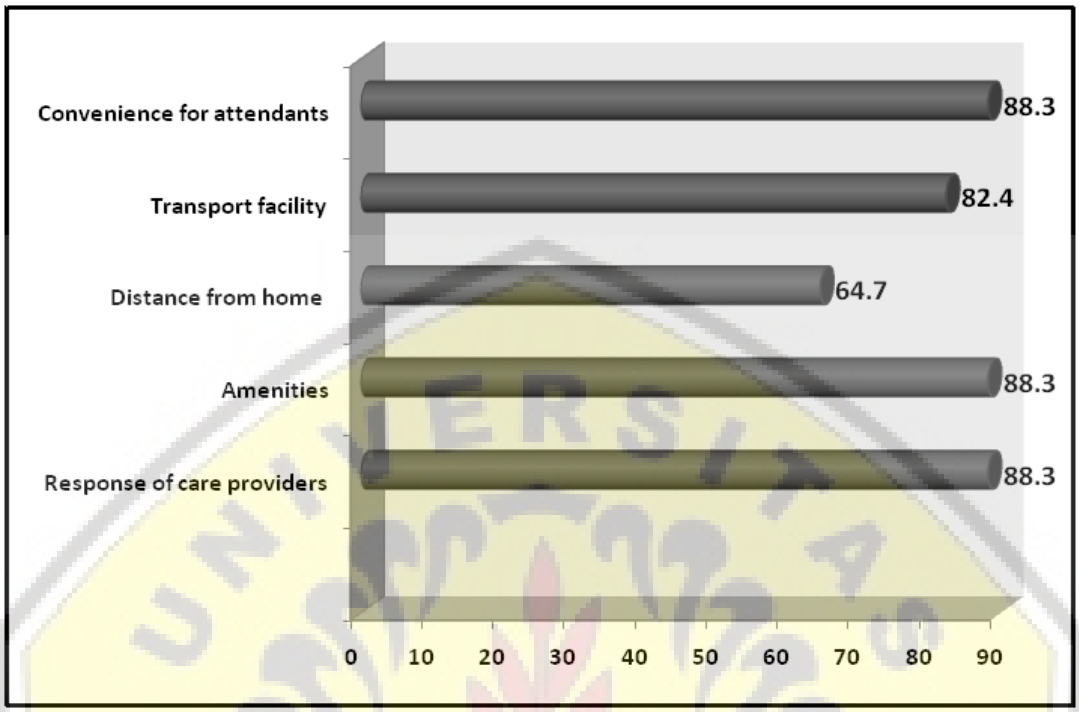

Figure 5: Barriers of Public Health Care Accessibility

The barriers in accessibility of public health facility were assigned following weights by the elderly:

a. Behavior of service providers.....88.3%
b. Distance from home.....64.7%
c. Transport facility.....82.4%
d. Amenities at the health facility.....88.3%
e. Convenience for attendants.....88.3%

Discussions

The awareness about locations of public health care facilities was found to be 84% in the study. However, mere awareness about location is not enough as poor people feel problem in finding appropriate person whom they may contact at the facility and in taking decision as to which health facility they should visit as is obvious from the findings that they chose to visit Dispensary for serious illnesses without realizing that serious illnesses may not be treated at dispensaries. Thus apart from unawareness about proper care providers, the ignorance about consequences of health problems also affects their health seeking behavior accessibility.

The public health facilities are meant for providing relief to poor population but doctors are not sensitive about this concept and resultantly the vulnerable population suffers the most.

Attendants were more worried about their own problems most important of which was earning bread and butter for their own family. So often they took the elderly person to the health care provider at a nearby facility as per their own convenience and when the problem was not cured they preferably got the person admitted in the government hospital where no one takes care and the person is unable to survive if not very fortunate.

This phenomenon also explains the importance of a son in the poor Indian families and high birth rate in want of a male child among poor population. For a son it is almost impossible to neglect his parents. That is why we could not find other social factors which may render elderly devoid of health care like carelessness of their younger family members. The elderly are also prone to abuse in their families or in institutional settings. This includes physical abuse (infliction of pain or injury), psychological or emotional abuse (infliction of mental

anguish and illegal exploitation) and sexual abuse. A study that examined the extent and correlation of elder mistreatment among 400 community-dwelling older adults aged 65 years and above in Chennai found the prevalence rate of mistreatment to be 14%. Chronic verbal abuse was the most common followed by financial abuse, physical abuse and neglect.

Time spent in accessing health care is crucial. In public health facilities waiting time is more than that in private health facilities. Time is important for the patient as well as for the attendant, as they are all daily wage earners and if half of the day is spent in hospital they tend to lose whole day's earning that ranges between Rs. 50 to 200 which is quite a big amount for them. Most of the participants in the FGDs complained about the time taken at SMS hospital for utilization of the services- "It takes at least 3–4 hours to take doctor's advice and medicines at SMS".

The other problem that the elderly mentioned is the overcrowding of the public hospitals. In the words of slum women- *"Satellite Mei ToSunwai Hi Nahi Hoti. Vahaan Jao To Boltei Hain- Baithja Na Baba AbhiDhekhtei Hain"*. Due to the over burden and patient load, the doctors and nurses could not give adequate attention to each individual. Most of the time they are perceived by the poor people as one who seems to overlook their problems. This situation discourages the poor to access the public health facilities.

Enquiry is made about their preference for private health facilities in response to which they said that apart from short distance it is the responsiveness of the care giver that matters most for them.

Amenities also constitute a barrier. Elderly generally do not go to a health facility alone. The amenities become important decisive factor because of the persons accompanying the elderly. During the study it was found that all the elderly have assigned due importance to amenities not only for them but also for persons accompanying them.

Higgs, Bayne & Murphy[5] used quantitative and qualitative approaches in obtaining their data about consumer's perspectives of health care. "Major barriers were cost, length of time one could get an appointment, lack of comfort with providers and having to miss work for appointments". We tried to capture response regarding selection of health care facility, however, only a few agreed that it was dependent on convenience of the family members. It seems that they did not want to blame their family members for their health. It is evident from the data that despite high cost of care in private health facilities they preferred to go there because of convenience of family members because length of time to get an appointment, lack of comfort with providers and wage loss actually are costs for the attendants as the jobless elderly had nothing to worry about these factors.

Conclusion

Data of this study reflects that major barrier in utilization of services by elderly slum dwellers are Behavior of service providers, Distance from home, Transport facility, Amenities at the health facility, Convenience for attendants.

Recommendations:

- In order to reduce waiting time at hospitals provision for exclusive service area for elderly can be made without much expense as presently there is no exclusive registration counter, OPD and diagnostic facility, etc. for elderly, which can help in reducing waiting time. Also we can ensure monthly health checkup of elderly in slums by a team of doctors' expert in geriatric care to reduce number of hospital visits.
- Keeping the role of 'Significant Others' in focus, a separate geriatric care hospital is needed with a capacity of at least 300 beds, ICU and OT and geriatrics trained staff, help desk and all amenities for attendants. Individual attention and facility of attendant care should also be there in the hospital.
- Doctors and staff of public health facilities need to be sensitized towards health care needs of the elderly on a priority basis.
- Provision should be made for free to and fro transportation facility to a nearby public hospital including SMS exclusively for elderly slum dwellers.
- Organization of awareness generation campaigns about free drugs scheme and other provision made available to the poor population for health and old age care including awareness about different services available at different public health facilities.

Comparison between Effect of Foot Exercise and Warm Water Foot Soak on Foot Edema among Antenatal Women

Mamta Vasaiya[1], Anjali Tiwari[2]

[1]M.Sc. Nursing, Manikaka Topawala Institute of Nursing, [2]Assistant Professor and HOD, Dept. of Obstetrics & Gynaecological Nursing, Manikaka Topawala Institute of Nursing, Charotar University of Science and Technology, Gujarat- 388421, India

Abstract

Introduction: Pregnancy is a precious phase in women's life, which has got various hormonal, psychological, vascular, metabolic and immunologic effects on the body. Foot edema commonly occurs during pregnancy because the gravid uterus exerts continuous pressure on the inferior vana cava during resting which interferes with venous circulation. Lower extremities edema is a common discomfort during pregnancy and is associated with daily activity limitation and discomforts[1]. The researcher aimed to compare the effect of foot exercise and warm water foot soak on foot edema among antenatal women.

Methodology: A quasi experimental, comparative study was conducted in selected hospitals of central Gujarat region. Conveniently 70 antenatal women with physiological foot edema were recruited. Out of these 70, 35 participants were randomly allocated to each Group A foot exercise and Group B warm water foot soak. The tool of data collection included a socio demographic and maternal variable performa and observational check list of figure of eight technique to measure the foot edema. Pre-treatment assessment was done for both groups. After interventions Foot edema was assessed by using tool of data collection for both groups.

Result: There was statistically significant effect found in relieving of foot edema in foot exercise group and warm water foot soak group. In both the groups p value were < 0.001 which depict that there was statistically significant effect fond in relieving of foot edema.

Conclusion: Foot exercise and warm water foot soak, both were found to be effective to reduce foot edema. But none were found to be superior to other. Both are cost effective, safe, non-pharmacological and easy to perform at home. Hence antenatal mother can use it easily to relieve their problem of foot edema.

Keywords: *Foot exercise, warm water foot soak, foot edema, antenatal women.*

Introduction

Pregnancy is a unique experience of every woman's life. It is a phase which most of the women sick to experience in her life. Pregnancy brings about a lot of changes in the body of the female as it is built over various hormonal, metabolic and psychological changes. Sometimes these changes can result in to minor ailments of pregnancy, of which one is foot edema. Lower extremities edema usually causes uneasiness during pregnancy and it also associated with restrictions in daily activities[2].

Edema can cause discomfort, pain, feeling of heaviness, night cramps etc. Various other measures have

Corresponding Author:
Ms. Mamta Vasaiya
M.Sc. Nursing, Manikaka Topawala Institute of Nursing, CHARUSAT, Gujarat
e-mail: mamtasangada@gmail.com

been recommended to decrease pregnancy related foot edema like isometric exercise, warm water immersion, aerobics, foot reflexology etc[3]. Ankle exercise helps good blood flow, restore range of motion and reduce swelling in the ankle[4].

Warm water therapy has shown its efficacy in increasing nourishment to tissue, calms and helps relax tension. It is a non-pharmacological, safe and side effect free, cost effective and easy to administer measure just like foot exercise[5].

Medication are usually contra indicated during pregnancy as they may interfere with the baby's development, hence complementary and alternative therapies such as massage therapy essential oils, exercise, water soak and herb can offer natural relief, without the stress of adverse reactions.

Material and Method

A quasi experimental, comparative, two group pre-test post-test design was employed for the present study. The study was conducted at selected hospitals of central Gujarat. Ethical clearance and formal permissions were obtained before the conduction of the study. 70 samples were conveniently recruited for the study, following which they were randomly allocated to either Group A: Foot exercise or Group:B Warm water foot soak (35 in each). Researcher developed perfoma was used to collect baseline data of the participants, whereas an observational check list for figure of eight technique was used to assess the foot edema. Pre intervention assessment of the foot edema was done for the participants of both the group. For Gorup A, the participants were asked to perform foot exercise 2 times a day for 3 days for a duration of 20 minutes, in which they had to initially sit with their legs well supported, than flex and stretch each ankle 20 times alternatively, followed by which they had to circle their each feet at ankle in both clockwise and anti-clock wise direction, 20 times each. For group B, the foot of participants were immersed till 3 inches above their ankle in the tub of warm water which was at a warm temperature comfortable for them to dip their feet, for the duration of 20 minutes, 2 times a day for 3 consecutive days. Post intervention assessment was done for both the groups after third day.

Results

Finding related to socio demographic and maternal variables of antenatal women of both the groups: Major findings of study depict that many participants in Group A belonged to 21-30 years of age group, whereas in Group B were from below 20 years of age group. Majority of participants of Group A had height between 151 -160 cm and Group B had 141-150 cm. In both the groups majority of participants weight were 51-60 kg. Most of participants from both groups had completed primary education and did house hold related moderate level of work. Both groups had majority primi gravida participants. Majority of participants from both the groups were having pregnancy of 25-32 weeks. Among both the groups, most of the participants were taking one hour of sleep during day time and 8 hours of sleep during night time.

Table No. 1: Findings related to effectiveness of foot exercise on foot edema among antenatal women

Group		Mean	Standard deviation	T-value	P value
Foot exercise	Day 1, pre intervention, right foot assessment	45.80	7.08	4.8820	<0.001
	Day 3, post intervention, right foot assessment	44.85	6.78		
	Day 1, pre intervention, left foot assessment	46.08	6.87	8.5080	<0.001
	Day 3, post intervention, left foot assessment	45.17	6.77		

It is as mentioned in table number 1. It clearly depicts that there was statistically significant effect of foot exercise on foot edema with p value < 0.001 for both the feet.

Table No. 2: Findings related to effectiveness of warm water foot soak on foot edema among antenatal women.

Group		Mean	Standard deviation	T-value	P value
Warm water foot soak	Day 1, pre intervention, right foot assessment	48.48	6.45	8.0430	<0.001
	Day 3, post intervention, right foot assessment	47.15	6.25		
	Day 1, pre intervention, left foot assessment	49.00	6.43	3.6230	<0.001
	Day 3, post intervention, left foot assessment	47.78	6.59		

It is as mentioned in table number 2. It clearly depicts that there was statistically significant effect of warm water foot soak on foot edema with p value < 0.001 for both the feet.

Findings related to compare the effectiveness of foot exercise and warm water foot soak on foot edema among antenatal women of both the groups: T- test was employed to compare the effectiveness of foot exercise and warm water foot soak on foot edema among antenatal women of both the groups. The analysis showed that in none of the group p value was <0.05. Hence it was interpreted that although both interventions are effective in reducing foot edema among antenatal women, but none of them were statistically better than the other (p>0.05).

Finding related to association between pre intervention foot edema and selected socio demographic and maternal variables: Fisher chi square test was used to determine the association for Group A, age ($\chi2$=31.518), height ($\chi2$=20.727) and weeks of pregnancy ($\chi2$= 44.89)were found to be associated (p value <0.05). Whereas for Group B, age ($\chi2$=31.405), height ($\chi2$=42.416) and weight ($\chi2$=56.566) were found to be associated (p value <0.05). Remaining all variables were found to be statistically independent (p value >0.05).

Discussion

The aim of the study was to identify the effect of foot exercise as well as warm water foot soak on foot edema among antenatal woman. A few studies have been conducted to relieve foot problems and regarding foot health during pregnancy. The current study revealed that there was statistically significant effect found in relieving of foot edema in both the groups at 0.05 level of significance. It also showed that none of the group p value was less than 0.05. Hence it was interpreted that although both interventions were effective in reducing foot edema among antenatal women, none of them were statistically better than the other (p>0.05). Thus both of the interventions can be used to relieve foot edema, as they are cost effective and easy to performby the antenatal woman, without requiring any special equipment or procedure. This study can be done on a larger and different type of population, at different geographical region to know about its usability.

Conclusion

The current study had focused on alternative solutions for home based non-medical measure to reduce foot edema which is easily accessible, cost effective and comfortable to use at home as well as hospital. Hence, nurses, community workers and antenatal women should be conscious about practice of such measure to ease the difficulty of antenatal women caused by foot edema.

The Potency of +Oxivarea towards Expression of TNF-α and IL1-β on Wounded Skin of Rat (Rattusnovergicus) Infected by Methicillin Resistant Staphylococcus Aureus (MRSA) Bacteria

Orchidara Herning Kawitantri[1], Agung Dwi Widodo[2], Boerhan Hidayat[3]

[1]Post Graduate School of Immunology Airlangga University, [2]Department of Microbiology Dr. Soetomo General Hospital, [3]Department of Pediatric Dr. Soetomo General Hospital

Abstract

Treatment of *Staphylococcus aureus* infection with antibiotics is often ineffective because the development of the strain provides resistance to the antibiotic, which is commonly called *Methicilin Resistant Staphylococcus aureus.+Oxivarea* is essential oil from the utilization of grape seeds oil, olive oil, lemon oil and nutmeg oil which has anti-microbial properties, polyphenol content and antioxidants. This study have an aim to investigate the potency of *+Oxivarea* towards expression of TNF-α and IL1-β on wounded skin of rat which are infected by MRSA bacteria. Experimental laboratory study with post-test only control group design. 36 male rats (*Rattusnovergicus*) which devided into 6 groups of treatment namely K1 and K2 (negative control wound without MRSA and +Oxivarea observation in 3 days and 5 days); P1 and P2 (MRSA without +Oxivarea, observation in 3 days and 5 days); P3 and P4 (MRSA and +Oxivarea, observation in 3 days and 5 days). The expression of TNF-α and IL1-β in each was measured with *Immunohistochemistry* method (IHC). The data was analyzed by calculate using measures of central tendency and the scatter, continued with *Kruskal Wallis* and *Mann Whitney* ($p<0.05$) to knowing the difference of every group. +Oxivarea give an effect with treatment of wounded skin rat infected by MRSA in TNF-α and IL1β expression with significant difference ($p=0.000$ and $p=0.007$; $p<0.05$). There was a potency of +Oxivarea with antimicrobial compound can decreased TNF-α and IL1β expression in wounded skin of rat infected by MRSA.

Keywords: *+Oxivarea, TNF-α, IL1-β, MRSA, Stapphylococcus Aureus.*

Introduction

Staphylococcus aureus is an opportunistic pathogen known for its ability to cause nosocomial infectious diseases starting from mild skin infections, such as impetigo to severe illness, endocarditis, pneumonia, sepsis and toxic shock syndrome. Nosocomial infection was a part of Health care-associated Infection which mean initially referred to those infection linked with admission to an acute-care hospital. The US Center for Disease Control and Prevention identifies that nearly 1.7 million hospitalized patients annually acquire HCAIs while being treated for other health issues and that more than 98,000 of these patients (one in 17) die due to HCAIs which most of them caused by *S. aureus*[1]. Methicilin Resistant Staphylococcus aureus (MRSA) infections differ throughout the world. an evaluation of 15 studies showed that 13 studies showed 74% of *Staphylococcus aureus* infections worldwide were caused by MRSA[2].

Host immunity to bacterial infections in wounds also plays a role in the healing process of the wound itself. The stages of healing the wound are controlled by a biologically active substance known as growth factors, namely a protein that can stimulate and activate cell proliferation, so that it can accelerate the wound healing process[3]. One growth factor that plays an important

Corresponding Author:

e-mail: orchidara.hk@gmail.com

role in the wound healing process is TNF-α and IL1-β which are a proinflammatory cytokines who works on immunity system[4].

Targeting the inflammatory pathway has high potential in preventing and eradicating disease. However, most drugs developed to date tend to be very expensive and are associated with adverse side effects. Therefore, there is an urgent need to develop new, safe, affordable and very effective agents that are expected to be an alternative management of inflammation caused by an illness [5].

+*Oxivarea* is an essential oil with the main ingredients are grape seed oil, lemon oil, olive oil and nutmeg oil. Where these ingredients have anti-microbial properties with polyphenol content and benefits in human health such as increasing bioactivity, antioxidants, anti-inflammatory, anti-bacterial, anti-cancer, antiviral, cardioprotective, anti-aging and anti-diabetic [6]. The previous study mentioned that+*Oxivarea* effective in inhibiting the growth of MRSA bacteria [7] and believed to help bacterial degradation by decreasing pro-inflammatory cytokines that are formed due to infection with MRSA bacteria with the mechanism of anti-microbial properties [6][7]. This study aims to determine the potencyl for + Oxivarea towards expression of TNF-α and IL1-β in Wound Skin of Rat infected by Methicillin Resistant Staphylococcus Aureus (MRSA) bacteria

Materials and Method

Study design and setting: This study was a true experimental with post-test only control group design. The sample consisted of 36 male Wistar rats, 200-250 gram body weight, 3 months old, then all samples were adapted about1 week before the treatment. This study had obtained study ethical with certificate number 452/ HRECC.FODM/VII/2019

Population and sample research: K1 group of rat is negative control wound without MRSA and +Oxivarea observation in 3 days, K2 group of rat is negative control wound without MRSA and +Oxivarea observation in 5 days, P1 group of rat which given wound with MRSA but without +Oxivarea, observation in 3 days, P2 group of rat which given wound with MRSA but without +Oxivarea observation in 5 days, P3 group of rat wich given wound with MRSA and +Oxivarea ±10mg twice a day observation in 3 days, P4 group of rat wich given wound with MRSA and +Oxivarea ±10mg twice a day observation in 5 days.

Preparation of Sample: Samples of rats were anesthetized using 10% ketamine at a dose of 20mg/kg body weight combined with 2% xylazine intramuscularly. On the back of the mice the hair is shaved in the middle of the back with a width of 3cm x 3cm, the next step is disinfection with povidone iodine 10%. The wound was by making incisions on the back of the mouse about ± 2cm, then closed using a transparent dressing which aims to create an ideal moist condition for wound healing and prevent contamination to the surrounding area.

+Oxivarea essential oil from PT. Surya Dermato Medica Laboratories. MRSA was given about 0.5 Mc Farland (1.5x108 CFU/mL) in P1, P2, P3 and P4. ± 10mg of Oxivarea + applied to the wound using cottonbud twice a day, in the morning and evening until the day the rat was decapitated. On the 3rd and 5th day all rats were extracted its tissues by using ether as an anesthetic, the skin on the back of treated rats was cut until the dermis layer was then fixed. Cutting the fixed skin tissue is done by processing including the stages of dehydration, clearing, impregnation and embedding. After becoming block paraffin, the tissues will be placed in glass object after cutting with microtom about 4-6 micron and ready to IHC examination.

Immunohistochemistry of TNF-α and IL1-β: The Examination of TNF-α and IL-1B expression was carried out using single immunohistochemistry and indirect staining. Calculation of IL-1β and TNF-α expression in cells was carried out in 10 visual fields with 400x magnification using a light microscope that gave a positive reaction to the anti-rat IL-1β and TNF-α with immunohistochemical techniques using TNF-α and IL-1B monoclonal antibodies (Santa Cruz Biotechnology, Inc. Europe). The expression of IL-1β is said to be positive if it is found in a brown colour on fibroblast cells that express IL-1β. The expression of TNF-α in tissues was showed with brown colour in tunica intima which showed the inflammation. All observation in microscope from 10 viewing fields with 400x magnification. The calculation is done by at least two readers (duplo) with at least two incision wound tissue preparations made, which are equipped with positive controls so the results are valid.

Data analysis: Data obtained were analyzed by means of *Kruskal Wallis* and followed by the *Mann Whitney* test ($p<0.05$) based on Kolmogorov-Smirnov normality test and Levene'shomogenity test ($p<0.05$) in Stastistical Package of Social Science (SPSS) Software 16.0 version (IBM corporation, Illinois, US).

Findings:

a. TNF-α: There were an expression of TNF-α about 3,3% in lymphocyte cell with low intencity in group wounded skin infected by MRSA with +Oxivarea in day 3 (P2) (Table 1). Meanwhile in day 5 observation of group P3 and P4, there were an expression of TNF-α about 34% in wounded skin infected MRSA, then decreased in group of wounded skin infected MRSA with +Oxivarea. The data were not normally distributed ($p<0.05$), so the analysis would be continued with non parametric test Kruskal Wallis with significant difference ($p=0.000$, $p<0.05$) and all the result of Mann Whitney ($p>0.05$).

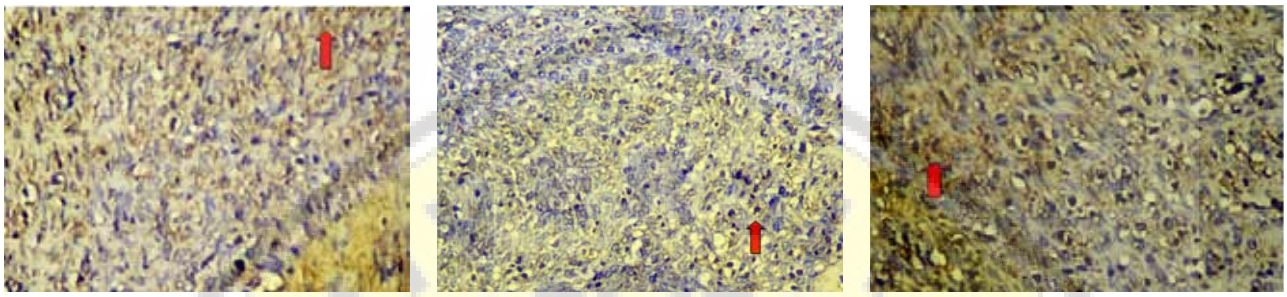

Figure 1. TNF-α expression in Wounded skin of rat infectedby MRSA. Positive expression of TNF-α presented in brown color in the lymphocyte (red arrow) in each group. P2, P3 and P4 group with 400x magnification.

Table 1. The mean ± Standart deviation (SD) of TNF-α expression in wounded skin rat between groups

Goups	n	Mean ± SD
K1	6	0.0 ± 0
K2	6	0.0 ± 0
P1	6	0.0 ± 0
P2	6	34.0 ± 17.84
P3	6	3.33 ± 8.16
P4	6	13.33 ± 20.66

Table. 2. The mean ± Standart deviation (SD) of IL1-β expression in wounded skin rat between groups

Goups	n	Mean ± SD
K1	6	0.0 ± 0
K2	6	0.0 ± 0
P1	6	1 ± 1.0
P2	6	0.0 ± 0
P3	6	0.0 ± 0
P4	6	0.0 ± 0

b. IL1-β: The results of observations of IL1-β expression on preparations of wistar rat skin consisted of calculation data that occurred in the control group, infection wound group and infectious wound group treated with + Oxivarea on day 3 and day 5 (Table 2) appeared just in P1 group (day 3 observation with MRSA without +Oxivarea) and increased after +Oxivarea treatment and 3 days after infection. The data were not normally distributed ($p<0.05$), so the analysis would be continued with non parametric test Kruskal Wallis with significant difference ($p=0.007$, $p<0.05$) and all the result of Mann Whitney ($p>0.05$).

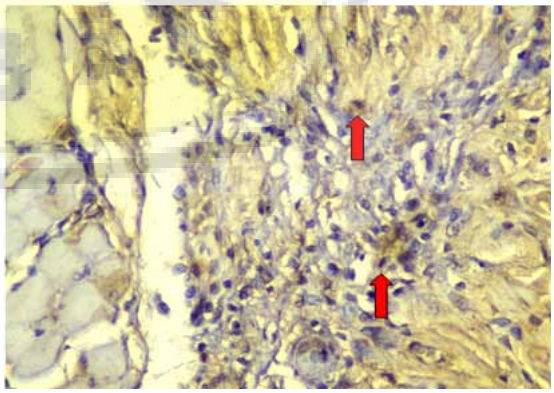

Figure 2. IL1-β expression in Wounded skin of rat infectedby MRSA. Positive expression of IL1-β presented in brown color in the lymphocyte (red arrow) in P2 group with 400x magnification.

Discussion

Through analysis of the calculation data by comparing the average value of TNF-α positive cell expression showed that the distribution of the number of inflammatory cells expressed TNF-α was different especially on the fifth day the expression of TNF-α decreased when given + Oxivarea with a group of mice that were injured and given MRSA without + Oxivarea administration. This shows that the antimicrobal constituent + Oxivarea active substance can kill bacteria, especially MRSA.

This indicates a decrease in the expression of proinflammatory cytokines as time passes for a longer + Oxivarea administration. Decreased levels of TNF-α, indicate the presence of control of inflammation and adequate progress in healing [8].

This study was conducted to determine the effect of + Oxivarea administration on wound healing especially in the inflammatory phase by observing inflammatory cells that express TNF-α. In this study the appearance of TNF-α expression increased on the fifth day where it was still expressed in the inflammatory phase after trauma to the skin (24 hours - 2 weeks). Inflammatory cells (neutrophils, macrophages) function to cleanse infections in wounds and debris and release dissolved mediators such as pro-inflammatory cytokines (TNF-α, IL1, IL-6 and IL-8) and growth factors such as (PDGF, TGF-β, TGF-α, IGF-1 and FGF) involved in the mobilization and activation of fibroblasts and epithelial cells for the next phase in the process of wound healing[9].

IL1-β expression in this study only occurred in the wound group with MRSA without the treatment of + Oxivarea at 3 days susceptible to infection. Where it is still in the inflammatory phase. In the wound group of MRSA infection with the addition of + Oxivarea after being compared with the group expressing IL1-β, the results of the decline. This can indicate that there is an effect of + Oxivarea on the decrease of IL-1β as proinflammatory cytokines that works on the day of the beginning of the inflammatory phase day because all the results of the expression on the fifth day show negative expression results.

+Oxivarea contains biochemical components such as polyphenol, methyl palmitate, methyl oleat, methyl stearate, methyl linoleic which have antimicrobial effects. Polyphenols are bioactive compounds found in fruits and vegetables that contribute to their color, taste and pharmacological activity. Grape seeds and olive oil are rich in polyphenols which are known for their antioxidant effects. Macrophages are also affected by polyphenols where macrophages are known to be key players in the inflammatory response. Active macrophages when starting inflammation by removing proinflammatory mediators and cytokines such as IL-6 and TNF-α. Polyphenols suppress macrophages by inhibiting cyclooxygenase-2 (COX-2), inducible nitric oxide synthase (iNOS), so they reduce the production of TNF-α, interleukine-1-beta (IL-1-β) and IL-6 expression. Polyphenols can modulate the NF-κB activation cascade at different steps by influencing IKK activation and regulating oxidant levels or by influencing NF-κB binding with DNA which leads to anti-inflammatory effects leading to the potential for this in dealing with chronic inflammatory conditions [9].

It can be concluded again that +Oxivarea can be said an anti-inflammatory because it can suppress IL1-β. IL1-β was produced by the activation of the nuclear factorkappa B(NF-κB) signaling pathway. In resting cells, NF-κB is found in the cytoplasm in the form of heterodimers. IκB prevents NF-κB from migrating to the nucleus. When the cell is activated IκBphospholizes into the release of NF-κB from IκB, which gives NF-κB the chance to move to the nucleus and begin transcription of genes that can be induced by NF-κB[10]. If NF-κB is suppressed by the presence of +Oxivarea it will inhibit the release of proinflammatory cytokines such as IL1-β.

Conclusion

It can be concluded that +Oxivarea have a potency by decreasing pro-inflamatory cytokines like TNF-α and IL1β in wounded skin of rat infected by *Methicillin Resistant Staphylococcus aureus* (MRSA).

Abstract

Background: Pregnancy related acute kidney injury (PR-AKI) is a serious problem occurring during pregnancy it may lead to feto-maternal morbidity and mortality.

Aim of the Work: To study the feto-maternal outcome in patients with PRAKI.

Method: 80 pregnant diagnosed with Pr-AKI according to American College of Obstetricians and Gynecologists, 2013 were studied and analyzed.

Results: Higher ranges of systolic and diastolic blood pressure. 56% fetal mortality and 23% of the babies need admission in neonatal intensive care unit with 80% recovery rate of renal function and about 15% became a CKD patients and 5% of cases died.

Conclusions: AKI complicating pregnancies is a common and serious problem. If recognized and treated promptly recovery is assured in majority of cases. Early identification and prompt management of preeclampsia and can prevent majority ofARF cases.

Keywords: *Pregnancy related acute kidney injury PRAKI, preeclampsia, feto-maternal outcome.*

Introduction

Pregnancy and childbirth are the times of celebration, but it may turn into a catastrophe and pregnant women can become suddenly severely ill. The intensity of evaluation and early management issues is great, because both woman and the infant will be at risk[(1)].

The development of acute kidney injury (AKI) in pregnancy, termed pregnancy-related AKI **(PRAKI)** which is a heterogeneous disease entity that occurs due to a multiple underlying etiologies. Regardless of the cause, it is the most important obstetrical complication which associated with significant maternal and fetal morbidity and mortality[(2)].

Definitions of AKI which commonly used vary from a mild increase in SCr level to the need for dialysis[(3)]. The American College of Obstetrics and Gynecology addresses the diagnosis of acute renal failure as a serum creatinine level of >1.1 mg/dL or a doubling of the serum creatinine concentration in the absence of other renal disease. The normally physiological changes that occur in the pregnant state seen to mask acute kidney injury (AKI) early in its disease course[(4)]. The true estimation of GFR during pregnancy is not reliable unless a timed urine creatinine excretion (24 hours urine creatinine clearance is used). Estimates used for non-pregnant individuals are not reliable in pregnancy[(5)].

The incidence of PR-AKI varies widely across

the world;it was reported incidence of 1 in 20,000 pregnancies to as much as 1 in 50 pregnancies due to many factors which contribute to this variation in incidence, as lack of uniform defining criteria, physiologic changes that occur in pregnancy that affect the interpretation of laboratory tests and regional differences in factors contributing to acute kidney injury (AKI). In addition, AKI (a term that has replaced acute renal failure) is often under-recognized until it is severe. Often there is a lack of information on baseline pre-pregnancy SCr values in this population, which further poses a problem [6].

It is reported that PRAKI has a bimodal distribution with an early peak of AKI as a consequence of septic abortions and a second peak due to hypertensive disorders of pregnancy, along with obstetric complications such as hemorrhage [7].

Patients and Method

This study has been conducted on 80 patients with (PR-AKI) in the emergency room and critical care unit of obstetrics and gynecology of Minia university hospital over the period from June 2017 to December 2018. The study was approved by the hospital's research ethics broad. All patients provided written informed consent.

The diagnosis of AKI in pregnancy was determined by the following criterion (any one of three): (American College of Obstetricians and Gynecologists, 2013): Serum creatinine > 1.1 mg/dl or doubling of serum creatinine from baseline, oliguria/anuria > 12 h duration, need for dialysis. All patients were submitted to complete history taking (including gestational age, parity and gravidity, history of maternal and neonatal complications and history of chronic illness) and examination was performed. Although observation of fetal and maternal morbidity and mortality.

Statistical Analysis: Data was collected and included in a data based system and analyzed by statistical package of or social sciences (SPSS) version 20. Parametric data were expressed as mean ± standard deviation (SD). It was analyzed statistically using student t-test while non-parametric data were expressed as percentages and were analyzed using chi square.

Results

Table (1): Parity and obstetric history

Previous obstetric history	MG	33(41.3%)
	PG	25(31.3%)
	Recurrent abortions	17(21.3%)
	Twins	5(6.3%)

Multigravida in 41.3% 0f patients, history of recurrent abortion in 17.5% and twins' pregnancy in 6.3%.

Table (2): Blood pressure measurements in patients:

Systolic BP	Range	(90-210)
	Mean ± SD	147.3±27.1
Diastolic BP	Range	(60-160)
	Mean ± SD	91.8±14.5

The systolic blood pressure ranges from 90 up to 210 and the diastolic blood pressure ranges from 60 to 160.

Table (3): Fetal outcome:

Fetal Outcome	Died 45(56%) NICU 18(23%) Live 17(21%)

It was observed that PRAKI resulted in 56% fetal mortality and 23% of the babies need admission in neonatal intensive care unit and only 21% live births.

Table (4): Maternal outcome:

Maternal Outcome	Resolved	64(80%)
	Died	4(5%)
	CKD	12(15%)

Most of PRAKI patients (80%) has a complete recovery of renal function and about (15%) became a CKD patients and 4 (5%) of cases died.

Discussion

It was found a significant increase in systolic blood pressure (SBP) and diastolic blood pressure (DBP). The different underlying causes as the causes of AKI in pregnant women are divided into three main groups: (1) obstetrical complications as septic abortion, anti-partum and post-partum hemorrhage, intra uterine fetal death (IUFD). (2) pregnancy-specific disorders as preeclampsia/eclampsia, HELLP, AFLP, TMA, hyperemesis gavidarum. (3) Miscellaneous causes as lupus nephritis, post infectious glomerulonephritis (GN), acute pyelonephritis[8]. **Arrayhani et al.,**[9] also found that hypertension was a common symptom in patient with P-AKI as PE count for (66.7%), with eclampsia in (13.5%) and HELLP syndrome in (58.3%) of them.

Also **Prakash et al.,** [10] postulated that PE/E was the commonest cause of P-AKI.**Pr-AKI** is also associated with significant fetal mortality and morbidity, this study found that (56%) was a fetal mortality and (22.5%) of the babies need admission in neonatal intensive care unit due to premature labor, this is in agreement with **Liu et al.,** [2]who postulated that the odds of perinatal mortality in pregnancy with AKI increases 3.4-fold when compared with pregnancies without **Pr-AKI.** Studies from India have reported high perinatal mortality of 20% to 45% due to intra-uterine death, stillbirth and prematurity [11]**.** In China, perinatal mortality was 17%, with higher mortality noted with **Pr-AKI** in the second rather than third trimester [8]**.** Premature delivery occurred in 40.9% patients and full-term delivery in 35.6%. Perinatal mortality was 23.5%, mainly due to intrauterine death (17.5%) and prematurity (6%) [10].

Reversal of AKI occurs following delivery of fetus in majority of patients with PE. However, persistent renal dysfunction and the need for long-term dialysis may occur lead to CKD development. The most common histological lesion in the setting of AKI in patients with PE/HELLP syndrome is acute tubular necrosis (ATN). However, renal cortical necrosis has been reported in preeclamptic women with AKI [12]**.**

In this study the final maternal outcome was (80%) of patients has a complete recovery of renal function and (15%) became a CKD patients and (5%) of cases died 3 cases died due to severe obstetric complication and one case died due to severe DIC. It was in agreements with others who found that less severe Pr-AKI demonstrates favorable renal recovery at 40% to 75%. In contrast, 4% to 9% of women with severe Pr-AKI remained dialysis dependent at 4 to 6 months postpartum [2]**.**The rate of progression to end stage renal disease from Pr-AKI, in general, range from 1.5% to 2.5% [13]**.** The risk of perinatal death is higher (26%) and increases with the severity of the renal injury [10].

Arrayhani et al., [9] obtained a total recovery in 76% of the cases, which is similar to the result that was found in this study. **Arora et al.,** [14]**, Goplani et al.,** [15] **and Erdemoğlu et al.,** [16] reported a total recovery of renal function in 42%, 54.3% and 61%, respectively.

Similarly, maternal mortality due to PRAKI represents less than 10% in Europe and North America but remains high in the developing countries [17]**.** Recent studies in India have shown a maternal mortality rate around 20% [17]. In Turkey, this rate was 10.6% [16]. In Pakistan, **Khalil et al.,** [18] reported a maternal mortality rate of 15% in 2011 compared to 33.3% of cases reported by **Chaudhri et al.,** [19].

The Institutional Ethics Committee approved this study of the School of Medicine, Minia University, Egypt and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

HIV Infection, Religion and Spirituality in Nigerian Community Settings

Vera Victor-Aigbodion

Postdoctoral Research Fellow, Department of Educational Psychology, University of Johannesburg, South Africa, Lecturer, Department of Educational Foundations, University of Nigeria, Nsukka.

Abstract

This article focuses on religion and spirituality regarding People Living with Human Immunodeficiency Virus (PLWH) in Nigeria. Specifically, the paper x-rayed the situation of HIV epidemic in Nigeria, followed by the impact of religion and spirituality on PLWH and finally the possible solution that can help to reduce the prevalence of the disease, as well as improve care and support of PLWH in Nigerian community settings.

Keywords: *HIV infections, Religion, Spirituality, Nigeria, Community Settings.*

Introduction

HIV epidemic is still a serious health challenge that demands serious attention. Presently, Sub-Saharan Africa accounts for 66% of all people with HIV infection[1] while 9% of PLWH globally are from Nigeria.[2] Moreover, about 3.3 million people live with HIV with a 3.6% adult HIV prevalence rate.[3] However, the Nigerian, Government is making tremendous effort to avert this epidemic through Anti-Retroviral (ARV) drug treatment. Nonetheless, less than 50% of PLWH in Nigeria are being diagnosed and treated to enhance their quality of life, reduce opportunistic infections and impact of HIV transmission in the community.[4] Studies have shown that the causes of stigmatization from members of the society that results to serious depression and anxiety among HIV-infected persons.[5] In addition, studies have also demonstrated that religious and spiritual care, coping skills and social support can be used as a mediator of perceived symptoms of stigmatization effects and improve health among those infected with HIV.[6]

Religion and spirituality reflects social support and thus can be employed as alternative and holistic treatment for PLWH.[5] Religion and spirituality can be a key role in both HIV infection prevention and care of PLWH within their community and congregation. Religion has been defined as the formal, institutional and outward expression of the sacred and has been measured by importance of religion, belief in God, religious attendance and prayer/meditation.[7,8] On the other hand, spirituality includes the internal, personal and emotional expression of the sacred and is often assessed by spiritual well-being, peace/comfort derived from faith and spiritual coping.[9] Previous studies revealed that an intensified religious and spiritual action is associated with less psychological distress, social functioning, greater energy and will to live, better cognitive functioning and feeling that life has improved since HIV diagnosis.[10,11] Nevertheless, religion and spirituality can also worsen outcomes because of likely belief on their religion faith and rejection of antiretroviral therapy and because of views of HIV as punishment from God for sinful lives. This paper tries to point out the existing knowledge regarding on religion and spirituality as it related to the roles religiosity and spirituality play in PLWH in Nigeria. Furthermore, the paper reviewed the negative impact religion and spirituality has on PLWH and finally the possible solution that can help to reduce the prevalence of the disease, care and support of PLWH in Nigerian Community settings.

The Bane of Religion and Spirituality among PLWH: The religion of a patient can affect the way he/she perceive health and disease and association with others.[12,13] Many spiritual patients strive to meet some religious needs related to their disease and failure to meet these needs may influence the type of life they live.[14] In addition, the form of spirituality (negative or positive) embraced by a patient may have a precarious

influence on the condition of the disease as revealed in earlier research.[15,16] Moreso, when a patient feels punished and abandoned by a higher power is termed negative spirituality and the feeling and believe that that God loves and forgives them despite their shortcomings is positive spirituality.[17] Patients may embrace negative spiritual/religious beliefs in preference to conventional treatment that may be detrimental to health-seeking behaviors, treatment adherence, survival and quality of life.[18] Previous researches have also showed that religion and spirituality may have a hurtful effects on HIV patients banished from their religious organizations because of the humiliation/misjudgment connected with being HIV-positive.[19,20] Some religious leaders and organizations have reacted with upright judgments and disapproval for people with HIV that have self-conscious behavior change.[21] Messages from the pulpit about sin and a 'bad death' due to AIDS have been common.[22,23] In an investigation of religious leaders in Nigeria.[24] establish that 54% of Christian leaders assumed that AIDS had been sent by God as a specific punishment for sexual license; a further 20% thought that it was a divine punishment covering other transgressions. Among the Muslim leaders, 68% claimed that it was wholly a divine punishment.[24] Despite these inadequacies, religion and spirituality has been characterized to promote acceptance and support for greater well-being of people living with HIV.

The Place of Religion and Spirituality in the Lives of PLWH: In Nigeria, religion and spirituality connects people of different races, class and nationality together, including PLWH. In addition, religious principles and exercises are entangled in the activities of the people and the leaders of churches, mosques and other religious communities play influential roles in determining the attitudes, opinions and behaviors. Researchers have shown that a religion/spirituality can assist PLWH in adoption of protective health behaviors.[10,25-34]

In Nigeria, religious institutions are spread throughout the country and have the capacity to reach a large number of people. The perception of HIV patients about their health, disease and interaction with relative, friends and neighbours can be determined by the way their religious and spiritual belief influences them.[35,12] Inspite of the hilarious effect of religion and spirituality on PLWH, some scholars have suggested that religious and spiritual influences can contribute immensely to high level of satisfaction with life in PLWHA.[34] Even more,[36] investigated the views and live experiences of men living with HIV/AIDS and suggested that religions such as Catholicism can promote acceptance and support for greater well-being of men living with HIV/AIDS. In addition, religiosity may become noticeable in the patients attitudes, religious services participation, improved religious beliefs which will show in the patients personal actions such as prayer. Positive relationship between religiosity and well-being in PLWHA is based on religion providing the basis of social support, recovery of meaning in life and a coping mechanism.[37,38] Therefore, since religion and spirituality could improve the adoption and practice of protective health behaviors[39], religious and spiritual-based HIV/AIDS prevention programs are assumed to be an effective way to decrease the prevalence of HIV/AIDS by encouraging harmless and less HIV risky behaviors. With this in mind, many religious organizations are getting involved in HIV/AIDS prevention education programs and are likely to be more effective in preventing the spread of HIV/AIDS.[40]

Conclusion

This paper presents a perspective on the state of knowledge on religion and spirituality regarding People Living with Human Immunodeficiency Virus (PLWH) in Nigeria. In Nigeria, religious institutions are spread throughout the country and have the capacity to reach a large number of people. The perception of HIV patients about their health, disease and interaction with relative, friends and neighbours can be determined by the way their religious and spiritual belief influences them.

Abstract

Aim of the Study: This study aimed to determine the effect of different glass ionomer in the healing of deep carious lesion after partial caries removal

Design: A total of 50 teeth of patients who fulfilled the inclusion criteria were selected to participate in the study. Then they were divided into two main groups: control group (Equia fill) and intervention group (Chemfill rock). Postoperative hypersensitivity (using thermal test and percussion test) and periapical lesions (using digital periapical radiograph) were tested in this period at the baseline (T0), after three months (T3) andafter six months (T6).

Results: Categorical data were presented as Frequencies (n) and Percentages (%). Fisher's exact and Cochran's Q tests were used to analyze inter and intragroup comparisons respectively. The significance level was set at $P \leq 0.05$ for all tests.

Conclusion: The hypersensitivity and periapical lesion was no affected by the type of glass ionomer.

Clinical Significance: Different type of glass ionomer can be used in deep carious lesion.

Keywords: *Deep carious cavities, glass ionomer cement, postoperative hypersensitivity, chem Fil Rock.*

Introduction

After the revolution in restorative materials due to the innovation of adhesive material and the change from the concept of drill and fill to biological model and conservatism, many techniques have been developed to treat deep carious lesion[(1)]. These techniques depend on decreasing the bacterial population allowing the remineralization of the remaining dentin by changing the ecological system by removing the superficial layer of carious dentin with the highest bacterial population and leaving the deepest layer of affected dentin (affected by bacterial acid that usually precede the bacteria itself) then sealing the cavity. Bacterial population has a main effect on the propagation of carious lesion, so elimination of bacterial acid increases the power of remineralization of infected dentin. One of these techniques is the partial caries removal [(2)].The success rate of partial caries removal is up to 91% [(3)].

The glass ionomer was the material of choice for this technique due to their biocompatibility, chemical

bond and fluoride release. Many modifications have been done to improve the glass ionomer properties, the addition of metal ions (silver and recently zinc) is one of this modification. Beside improving the mechanical properties, it was found that the addition of metal ion to glass ionomer decrease the bacterial growth[4]. Few clinical studies have evaluated the role of antimicrobial agents incorporated into restorative materials and their potential anti-caries effect [5]

Zinc increase the uptake of fluoride and enhance remineralization by preventing the surface remineralization (allow better penetrate of fluoride into deeper surface (prevent lesion arrestment). Zinc also bind with the hydroxy apatite crystal making it less soluble in acid[6].Multiple in vitro studies showed that Zn modified glass ionomer has better mechanical performance and antibacterial action [7, 8] but due to lack of evidence from enough well conducted clinical studies, this study will be conducted.

The null hypothesis was that both conventional glass ionomer and zinc modified glass ionomer are successful in the management of deep carious lesion.

Material and Method

A total of 50 teeth of patients who fulfilled the inclusion criteria were selected to participate in the study. Consent was taken from each patient prior to the commencement of the study. Teeth were divided into 2 main groupsby utilizing simple random sampling method each group was 25 participants according to base material tested. The selected participants were divided into two groups: group ($\mathbf{A_1}$) control group (EQUIA fill) and group ($\mathbf{A_2}$) intervention group (CHEMFILL). The study took place over a period of six months (**T**). Postoperative hypersensitivity and periapical pathosis were tested in this period at the baseline ($\mathbf{T_0}$), after three months ($\mathbf{T_3}$) and after six months ($\mathbf{T_6}$).

Simple randomization has been used every patient took a number from 1using random integer set generator. The assessor was blind, but due to the difference in the material, the operator did not been blinded.

Clinical Procedures:

Preoperative clinical assessment: A detailed chart for each patient was taken. A proper pain history was taken to exclude the absence of any signs of irreversible pulpitis. Clinical examination was done to find any sign of inflammation like swelling, fistula or abscess. Cold pulp testing was done to ensure pulp vitality using Refrigerant spray (Endo Frost, Roeko, Coltène/ Whaledent, Germany). The spray is applied by a cotton pellet and the patient told the operator in case of pain sensation. Percussion/palpation and mobility tests were performed, Periapical digital radiograph was performed (T0) to detect the presence of any periapical lesion or widening in periodontal ligament. These tests were repeated each follow up visit at T3 and T6.

Caries Removal Procedure: Local anaesthesia was given to the patient, then isolation using rubber dam was done. Access to carious lesion using high speed hand piece.The removal of Deep carious tissue was performed following the guidelines published by the International Caries Consensus Collaboration (ICCC) **.**The caries was selectively removed using spoon excavator *(no51,52, Dentsply, Maillefer)* The caries was totally removed from the cavity wall with spoon excavator or low speed hand piece with carbon-steel rose-head bur to perform a proper marginal seal.Glass ionomer restoration were applied according to manufacturer instruction.

Results

Postoperative hypersensitivity: Frequencies (n) and Percentages (%) of Postoperative hypersensitivity incidence in both groups were presented in table (1)

Fisher's exact test showed no significant difference in the occurrence of postoperative hypersensitivity at baseline (P=0.667) and after 3 months (0.500), while after 6 months there was a significant difference between both groups (P=0.025). At baseline both groups had the same percentage of occurrence of postoperative hypersensitivity (13.0%). After 3 months the percentage decreased in the control group to (8.7%) while remaining fixed in the intervention arm. After 6 months there was no incidence of postoperative hypersensitivity in the control group, while intervention cases suffering from sensitivity increased from (13.0%) to (21.7%) by the end of the follow-up period.

Periapical Lesion: Frequencies (n) and Percentages (%) of periapical lesion incidence in both groups were presented in table (2)

Fisher's exact test showed no significant difference between both groups regarding the occurrence of periapical lesions after 3 and 6 months (P=0.500). Starting from baseline till the end of the follow-up

period, members of the intervention group were free from periapical lesions. While for the control group only (4.3%) of participants had periapical lesions starting from 3 months till the end of the follow-up period.

Table (1): Frequencies (n) and Percentages (%) of postoperative hypersensitivity incidence in both groups

Discussion

In this study we use the partial caries removal techniques[9] as treatment for deep cavitated lesion according to the recent consensus recommendation that support it success, less risk of pulpal exposure and less cost compared to other alternative techniques like step wise excavation [10]. Clinical studies showed that No risk to left infected dentine under the restoration sufficiently sealed and no need for re-entry to remove the residual dentine. It showed high success rate both clinically and radiographically.[11, 12]

In our study, we use two different type of high viscosity glass ionomer as with the Minamata Convention the use of mercury will be phased down and this undoubtedly will influence dental treatment regimens and economic resources[14]. Zinc modified glass ionomer is a new one of metal modified glass ionomer as zinc substitution calcium ions in the crystalline structure of glass ionomer resulted in increasing the density of glass as zinc due to higher atomic dentist of zinc ion.[15] This substitution results an increase in oxygen density which represent the degree of atoms packing in glass which increase the strength and fracture toughness of glass ionomer[16]. In addition, the zinc has an antibacterial property and remineralizing effect, low concentrations of zinc can both reduce enamel demineralisation and modify remineralisation but its effect on caries is not yet determined[6].Zinc can interact with hydroxyapatite crystal by adsorption onto crystal surfaces and/or incorporation into the crystal lattice which result a decrease in hydroxyapatite solubility, Zinc also can modify the crystal-growth of orally relevant calcium phosphates [6].

Most of dentist use the clinical sensitivity to hot and cold for assessment of pulp vitality, for many years the clinical sensitivity was considered irrevalant, but according to the study conducted by **Ricucci et al.,2014,**[17] there was a good correlation between the clinical sign and histological status of the pulp. **Pigg et al., 2016**[18] stated that the cold test using the endofrost

had good validity to distinguish a vital pulp from a nonvital pulp.

Our follow up visit was scheduled after 3months and six months. The available evidence supports that the peak of increase in dentin microhardness and dentistry is the first 3 months after partial caries removal. This may be due to decrease of bacterial activity, reorganization of collagen fibre and the increase in calcium ion concentration [19].as the pulp death could occur and remain silent a second visit is scheduled at 6 months to give more chance dentin formation [20].

The result of our studies showed that for hypersensitivity assessment both material (zinc modified and conventional glass ionomer) showing no statistical difference at base and 3months follow up while there was a statistical increase in the postoperative hypersensitivity after 6 months favouring the control. **Molina et al, 2013**[8] and **Molina et al 2014**[21] support this result. this could be attributed to many factors like the size of the cavities type of occlusion of the patient and the minor variable in the pulp response[22].Another factor is the mechanical properties, the Equia fill showed higher diametral and flexure strength than the Chemfill rock[7,23]. This could affect the clinical performance of glass ionomer and sealing ability of lesion and the lesion and the ingress of fluids,[24] **Giray et al 2014,** support that the microleakage with Chemfill rock is higher than the Equia fill on the other hand [25]**el Deeb and Mubarak 2018**, reported that bonding properties of Chemfill rock to stimulates carious dentin is better than the Equia fill.

Regarding the periapical lesion, there was no significant statistical difference between the two group or within the same group during the follow up periods, which could confirmed that partial caries removal and sealing of carious lesion is a successful line of conservative treatment for deep carious lesion [9, 11]. Even with the absence of statically difference two cases of the control group showed periapical lesion. This result could interpreted by the selection criteria of case and the possible variation between the clinical sign and symptoms and the histopathological status of the pulp[17] also its may contributed to the increase of ion release in the zinc reinforced glass ionomer which may result higher remineralization of affected dentin, increase the dentin hardness and increase the antibacterial effect[26], also[27] **Prudencio et al 2003,** found that the addition of zinc to glass ionomer present an increase in fluoride release than conventional glass ionomer.

Within the limitation of this study, the results supports that the partial caries removal could be the technique of choice for management of deep carious lesion without the need of second re-entery, this finding are in agreement with[9,28] also the result of our study support that glass ionomer could be used as final restoration especially due its less techniques sensitivity, time,cost of treatment which of mean concern due to the large national expenses on the dental health each year.

Conclusion

We concluded that both type of glass ionomer could be used successfully in deep caries management. the postoperative hypersensitivity and pulpal reaction were not affected by the type of restoration. The technique of caries removal could be effective factor in preservation of pulp vitality

Clinical Significance: Different glass ionomer could be used in treatment of deep cavities but further studies to assess the survival rate as final restoration

Funding: The study was self-funded

Competing Interests: No conflict of interest

Ethical Approval: The Ethics and research committee, Faculty of Dentistry, Cairo University approved the study and patients' consent was obtained.

Nasal Versus Oral Feeding Tube Placement: Selected Outcomes among Preterm Infants

Salwa M. Ahmed[1], Hanan M. Rashad[2], Hoda A. Mahmoud[3], Tamer A. Abd El Hamid[3]

[1]Clinical Instructor, [2]Assistant Professor, [3]Lecturer, Pediatric Nursing, Pediatric Nursing Department, [4]Assistant Professor, Pediatric Medicine, Pediatric Medicine Department, Faculty of Medicine, Cairo-University

Abstract

Background: Enteral feeding tubes for preterm infants may be placed via either the nose or mouth. Nasal tube placement may compromise respiration, however, orally placed tubes may be more prone to displacement.

The Aim: The current study was to determine the effect of nasal versus oral placement of enteral feeding tubes on weight and the incidence of adverse events among preterm infants.

Method: A descriptive comparative study design was utilized.

Sample: A convenient sample of sixty physiologically stable preterm were assigned to two equal groups within six months (between July 2018–Jan. 2019). They were recruited from neonatal intensive care units of both Kasr Alainy and El-Monira Pediatric Hospitals-Cairo University.

Tools: Three tools were developed by the researchers: preterm infant's characteristics, observational checklist forincidence of adverse events and recording sheet for daily weight and time to sustain full oral feeding.

Procedure: The researches recorded preterm infant's characteristics, any adverse events, weight and time to sustain full oral feeding in the morning shift twice a week for two weeks.

Results: Orogastric tube feeding was statistically significant different compared to nasogastric tube feeding regarding displacement. There was no difference among two groups in weight gain, time to reach full feeds and frequency of adverse events. Orogastric tube feeding group had lesser duration of hospital stay than nasogastric and orogastric tube feeding group reached to full oral feeds quickly compared to nasogastric with no statistical significant differences.

Recommendation: Further researches with a larger population would probably be required to know the significance of this outcome.

Conclusion: This study concluded that no differences were found between both orogastric and nasogastric tube feeding on preterm infants' weight, incidence of adverse events and time to sustain full oral feeding.

Keywords: *Nasogastric tube, orogastric tube, Preterm Infants, outcomes.*

Introduction

When preterm infants are too immature or unwell to suck feeds they can receive their milk through a feeding tube passed via either the nose or the mouth. The establishment of safe oral feeding in preterm infants may be delayed because of poor co-ordination of sucking and swallowing, neurological immaturity and respiratory compromise. Enteral feeds may be delivered through a catheter (feeding tube) passed via the nose or via the mouth into the stomach or upper small intestine[(1)].

Neonates are obligate nose breathers. Feeding tubes placed via the nose can cause partial nasal obstruction, increased airway resistance and increased work of breathing[2,3]. This increase in energy expenditure may potentially affect growth and development. Nasogastric intubation through the larger nare may increase airway resistance as the preterm infant is forced to breathe through an airway of smaller calibre. In addition, individual differences in nasal size may be acquired secondary to the effects of nasogastric tubes [4].

Incorrect placement, or subsequent displacement, of feeding tubes into the lower oesophagus or into the lung can lead to aspiration, respiratory compromise and increased energy expenditure[5]. Orally placed tubes may be easier to displace as they can loop inside the mouth. Repetitive movement of the orally placed tube may result in mucosal trauma and may increase the incidence of apnea and bradycardia due to vagal stimulation [6]. There is not enough data to make any recommendation regarding the superiority of either routes of feeding [7].

Aim of the study: To determine the effect of nasal versus oral placement of enteral feeding tubes on weight and the incidence of adverse events among preterm infants.

Research question: What are the differences between nasal and oral placement of feeding tube on weight and the incidence of adverse events among preterm infants?

Material and Method

Research Design: A descriptive comparative study design was utilized.

Participants: A convenient sample of 60 preterm infants were assigned to two equal groups within six months (between July 2018 – Jan. 2019).

Tools of Data Collection: Three tools were developed by the researchers after extensive review of related literature: preterm infant's characteristics, observational checklist and recording sheet for weight and time to sustain full oral feeding.

Tool Validity and Reliability: Data collection tools were submitted to three panel of experts in the field of high risk neonates to test the content validity. Reliability was done by cronbqch's alpha test and the result was 0.82.

Procedure: After the preterm infants had initial physiological stable state, they assigned to receive either nasogastric or orogastric feeding, the researchers' recorded preterm infant's characteristics once from admission sheet using tool I. They assessed any adverse events such as apnea, displacement and injury (trauma) in the morning shift twice a week for two weeks using tool II. All infants were weighed each morning, naked, before feeding and bathing, on one same time and time to sustain full oral feeding was recorded for all preterm infants using tool III.

Results

It was evident from table (1) that there were no statistically significant differences between orogastric and nasogastric groups regarding their gender, diagnosis and gestational age ($p > 0.05$).

Table (1): Characteristics of Preterm Infant's Characteristics For Both Groups In Percentage Distribution (N=60)

Preterm Infant's Characteristics	Groups				P
	Orogastric (n=30))		Nasogastric (n=30)		
	N	%	N	%	
Gender					
• Male	17	56.7	13	43.3	0.219
• Female	13	43.3	17	56.7	
Diagnosis:					
• RDS	27	90	25	83.3	
• M.A	3	10	3	10	0.729
• Sepsis	-	-	2	6.7	
G.A.					
• <32 Weeks	9	30	13	43.3	0.284
• 32-37 Weeks	21	70	17	56.7	

Note: RDS = Respiratory distress syndrome, M.A = Meconium Aspiration, C.S = Cesarean Section NVD = Normal Vaginal Delivery, G.A: Gestational Age

Table (2): Hospital Stay For Both Groups In Percentage Distribution (N=60)

It was revealed from table (2) that there were no statistically significant differences between orogastric and nasogastric groups regarding their hospital stay ($p > 0.05$).

Hospital Stay	Groups				P
	Orogastric (n=30)		Nasogastric (n=30)		
	N	%	N	%	
• One-<two weeks	1	3.3	-	-	
• Two-<three weeks	6	20	3	10	
• Three-<four weeks	2	6.7	5	16.7	
• Four weeks and more	21	70	22	73.3	
Mean±SD	41.27±18.984		41.47±17.190		0.346

It was illustrated from table (3) that there were no statistically significant differences between both groups regarding their daily weight at the four measures.

Table (3): Daily Weight At 1st, 2nd, 3rd And 4th Measures In Percentage Distribution (N=60).

Daily Weight	Groups		P
	Orogastric	Nasogastric	
	Mean±SD	Mean±SD	
1st Measure	1699.17±340.018	1606.50±354.951	0.190
2nd Measure	1693.83±332.586	1621.33±357.247	0.598
3rd Measure	1724.00±329.897	1693.00±351.027	0.211
4th Measure	1740.00±327.246	1712.00±337.062	0.270

Table (4): Time To Sustain Full Oral Feeding For Both Groups At 1st, 2nd, 3rd And 4th Measures In Percentage Distribution (N=60)

It was represented from table (4) that there was no statistically significant difference about time to sustain full oral feeding for both groups ($p > 0.05$).

Time to sustain full oral feeding	Groups				P
	Orogastric		Nasogastric		
	N	%	N	%	
• < a week	2	6.7	4	13.3	
• Week-<two weeks	11	36.7	9	30	
• Two weeks-<three weeks	4	13.3	2	6.7	0.287
• Three weeks-<four weeks	3	10	7	23.3	
• Four weeks and more	10	33.3	8	26.7	

Discussion

There was limited data available on the effect of the nasal versus the oral route for placing feeding tubes in preterm or low birth weight infants.

In relation to preterm infant's characteristics. The current study revealed that more than half of the preterm infants were males in the orogastric group, while more than half were females in nasogastric group. This findings goes in the same line with[8], who reported that more than half of preterm infants in both orogastric and nasogastric groups were males. While[9] contradicted these findings and reported that more than half of nasogastric group were males, while in orogastric group, a relatively high percentage of preterm infants were females.

The result of the current study revealed that more than three quarters of preterm infants were diagnosed

with RDS in both groups. This study goes in the same line with [10], who found that more than two thirds of neonates had RDS.

Regarding gestational age, [8] who studied Mode of gavage feeding: does it really matters, reported that the highest percentage of preterm infants in both orogastric and nasogastric groups their gestational age were ≥30 - <32 weeks and this contradicted with the result of the current study which revealed that more than two thirds of orogastric group and more than half of nasogastric group preterm infants were born between 32-37 weeks of gestation with no statistically significant differences of both groups.

Hospital stay was slightly longer in nasogastric group than orogastric group but with no statistically significant differences among both groups, as mean duration of hospital stay was 41.47 days in orogastric group and 41.47 days among nasogastric group. This result contradicted with the study of (9). Who revealed that there was no much difference among two groups. Mean Duration of hospital stay was 35.38 days with standard deviation of 7.60 among Nasogastric tube feeding group and 37.54 days with standard deviation of 9.45 among Orogastric tube feeding group.

Preterm infants in orogastric group gained weight more than those in nasogastric group at 1st, 2nd measures, 3rd and 4th measures. As mean of weight were (1699.17, 1693.83, 1724.00 and 1740 respectively) in orogastric group and (1606.50, 1621.33, 1693.00 and 1712.00 respectively) in nasogastric group but there was no statistically significant differences. This findings supported by [9], who demonstrated that mean time to regain birth weight was 19.38 days among Nasogastric tube feeding group and 19.23 days among Orogastric tube feeding group. Also (11), who studiedcontinuous feeding promotes gastrointestinal tolerance and growth in very low birth weight infants, reported no statistically significant difference in the time taken to regain birth weight.

Regarding adverse events of both orogastric and nasogastric tube placement, the results of the current study delineated that, there was no statistically significant differences between both orogastric and nasogastric groups about injury at the 1st, 2nd, 3rd and 4th measure. This findings supported by [9], who concluded that there were no significant differences among two groups to frequency of adverse effects.

Concerning displacement, the current study illustrated that there was statistically significant difference between both orogastric and nasogastric groups at the 2nd measure (p= 0.050), while there were no statistically significant differences between both groups about displacement of the feeding tube at the 1st, 3rd and 4th measures. This findings supported by [8] who reported that the episodes of non-intentional removal and displacement are more in OGT group and it statistically significant (p = 0.012 and p<0.0001 respectively). Also, [9], reported thatfrequency of tube displacement was more common among Orogastric tube feeding compared to Nasogastric tube feeding. Which was statistically significant with a p-value of 0.001, mean difference of -0.4462 times/day.

In the matter of apnea, the results of the current study showed that there were no statistically significant differences between both orogastric and nasogastric groups about episodes of apnea at the 1st, 2nd, 3rd and 4th measures. This findings goes in the same line with [8], who reported that episodes of apnea, bradycardia, desaturation and oxygen requirement are more in NGT group as compared to OGT group but statistically Insignificant OGT versus NGT (p = 0.86).

For time to sustain full oral feeding, the highest percentage of both orogastric and nasogastric groups reach to full oral feeding by one week to less than two weeks from starting oral feeding. There were no statistically significant differences about time to sustain full oral feeding for both orogastric and nasogastric groups. This finding was in agreement with [8] who found that orogastric tube group neonates required (6.18±0.61) days as compared to Nasogastric tube group neonates as they required (6.47±0.59) days to achieve full feeding but it is statistically insignificant (P =0 .368).

Based on clinical observation. The differences between both groups in terms of outcome measures like duration of hospital stay, time to reach oral feeds were not statistically significant which may be due to small sample size and there is need of larger samples and also further continuation of this study to know the significance of these outcomes.

Conclusion

This study concluded that no differences were found between both orogastric and nasogastric tube feeding on preterm infants' weight, incidence of adverse events and time to sustain full oral feeding.

Ethical Clearance: Acceptance of ethical committee at faculty of nursing, in Cairo University was gained. All studied neonates' parents were informed about the aim, procedure, benefits and nature of the study and the written consent was obtained from them. The confidentiality of information was assured.

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: There are no resources of fund.

Abstract

Background: Celiac disease is an autoimmune disease induced by gluten in genetically predisposed individuals. However, celiac disease is generally associated to malnutrition especially in children and adolescents.

Materials and Method: The survey was carried out on 132 celiac patients in the region of Rabat between the year 2015 and 2018. Weekly dietary frequency and Mediterranean index KIDMED was used to evaluate the dietary balance.

Results: A 132 children and adolescents with celiac disease participated in the study of which 59.8% (n = 79) of the respondents were female and 40.2% (n = 53) were male. The average age of patients was 14.34 ± 0.2 years, with a minimum age of 10 years and a maximum age of 16 years.

The result of KIDMED classification (crombach alpha = 0.80) showed that 28.8% (n = 38) of children had a very poor level of adherence to Mediterranean diet, 57.6% (n = 76) in need of improvement and 13.6 % (n = 18) were in optimal Mediterranean diet. In the other hand, 84.26%, 86.04% and 54,45% of respondents reported consuming maize, sorghum and rice more than 4 times/week respectively.

Conclusion: It has been found that the diet of most of the individuals surveyed during this study having followed a diet consisting of cereal (maize, sorghum, millet and rice) without gluten allows them having a growth and a more or less correct corpulence. Consequently, these celiac patients manage to meet their nutritional needs in an acceptable way.

Keywords: *Celiac Disease - KIDMED - Gluten free diet- pseudo cereal.*

Introduction

Celiac disease (CD) affects people in all parts of the world. In last decades celiac disease thought to be a rare childhood syndrome, but currently the celiac disease known to be a common autoimmune genetic disorder[1]

Celiac disease can be effectively treated by a strict, life-long adherence to a gluten-free diet[2]. The absence of gluten in natural and processed foods represents a key aspect of food safety of the gluten-free diet A promising area is the use of minor or locale pseudo-cereals like, sorghum and millet the aim of our study is to find the place of the naturally absence gluten in pseudo-cereal in the dietary balance of the participants.

The Mediterranean Diet is associated with many positive health benefits. . It suggests the high intake of vegetables, fruits, whole grains, legumes, healthy fats and water; a moderate consumption of seafood, poultry and dairy; and a low intake of sweets and processed or red meat. For patients with celiac disease, the Mediterranean Diet can help provide important nutrients that a typical gluten-free diet may lack—without the significant risk of undesired weight gain that can lead to overweight or obesity[3] . And the diet can easily be made gluten-free.

Method

Population: The survey was carried out on 132 celiac patients under strict gluten-free diet for a year, in the region of Rabat. It was conducted by experienced dietician, between 2015 and 2018.

KIDMED Index: The quality of the diet was assessed using the KIDMED index (Mediterranean food quality index for children and adolescents)[4] . The KIDMED index is based on the principles of the Mediterranean model diet, because of its good correlation with the improvement of glycemic control and cardiovascular health.[5]

Frequency of consumption questionnaires: The participants were asked to check, for each food on the list, the frequency closest to their usual consumption. Prior knowledge of the eating habits of the studied population and the determination of the objective of the questionnaire make it possible to choose the elements to be included in the questionnaire and to determine its length. The consumption data collected at the individual level was transformed into digital data[6] .

Statistical Analysis: The quality of the diet was estimated using the KIDMED index (Mediterranean Food Quality Index for Children and Adolescents). It was deduced from a 16-items for wich the scores are classified into three groups : (score ≤ 3: very poor quality); (4≤score≤7: need for improvement) and (score≥8: optimal Mediterranean diet).

BMI (body mass index) is calculated according to WHO standards: (overweight :> + one standard deviation, type (equivalent to IMC 25 kg/m²); Obesity: > + two standard deviations, equivalent to a BMI of 30 kg/m²) and Slimming: <- two standard deviation [7].

After filtration, the collected data captured on a support designed for exploitation, then analyzed and interpreted. The qualitative characteristics expressed in percentages and the quantitative characters translated into mean ± standard deviation. The tests applied are those of chi-square, students and multiple correlation.

Results

KIDMED Index: The study carried out on 132 celiac patients chosen in a simple and random way and having completely answered all the asked questions show that 59.8 % (n = 79) of the respondents are female and 40.2% (n = 53) are male. The sexe ratio is not balanced (female/male ratio = 1.49). In addition, the distribution of the respondents shows that the average age of patients was 14.34 ±0.2 years, with a minimum age of 10 years and a maximum age of 16 years. The distribution satisfies Gaussian conditions (asymmetry coefficient = -0.59 ± 0.21 and flattening coefficient =-1.05 ± 0.42). The distribution of celiac patients according to the environment of origin shows that 74.2% (n = 98) come from the urban environment against 25.8% (n = 34) from rural regions. With respect to the socio-economic level, 66.4% (n = 85) of the patient's progress to a middle social level, 17.4% (n = 23) of low social leveland 18.2% (n = 24) answered that they come from a high social level.

The anthropometric study of patients according to their body mass index revealed that 78.79% (n = 104) have an index of between 18.5 and 25, which corresponds to the category of persons with a corpulence according to WHO. In addition, 12.88% (n = 17) were underweight, of which 16 cases out of 17 were between 10 and 12 years old and 8.33% (n = 11) were overweight and all are female and over 16 years old. For size-at-age growth, the distribution of Z score corresponding to each child shows a prevalence of 17.42% (n = 23). These stunted children are all between 10 and 12 years old

The distribution of celiac children by sex, age group and degree of diet quality presented in Table 1. As a result, 30.30% (n = 40) of children were in very low adherence to Mediterranean diet, 32.57% (n = 43) were in need of improvement and 37.12% (n = 49) were in optimal Mediterranean diet. Moreover, female children (n=17) aged 10 to 12, 13 out of 17, need improvement and 4 out of 17 are in optimal Mediterranean diet. While among female children aged 13 to 15, only one girl out of 12 is in a very low adherence to Mediterranean diet and another 5 girls need improvement,while the remaining six girls assumed normal. However, in female children over the age of 15, 56% (n = 28) were in very

poor food quality, 32% (n = 16) need improvement and 12% (n = 6) were in an optimal Mediterranean diet state. In the other hand, male celiac children with very low adherence to Mediterranean diet were those aged 10 to 12 years (n = 6) and over 15 years (n = 5). However 9 male children, under 15 years old, need a nutritional improvement and 62.26% (n = 33) of the men are on optimal Mediterranean diet

Distribution of food frequency: The table 2 shows the frequency of consumption per week for each food group. Food quantities were estimated using a "Food portion guide" reference manual[8]. In addition, 84.26% 86.04% and 54,45% of respondents reported consuming maize, sorghum and rice more than 4 times/ week respectively. However, more than 75% of the respondents answered to consume vegetables and fish 4 times and more per week. Similarly, over 54% confessed to consuming more than 4 times a week rice and fruits.

Table 1. Distribution of celiac children by sex, age group and diet categories (frequency-expressed results).

Standard	Gender						Total
	Female (n=79)			Male (n=53)			
	[10-12]	[13-15]	> 15	[10-12]	[13-15]	> 15	
Very Bad Quality	0	1 (8,33%)	28 (56%)	6 (33,33%)	0	5 (25%)	40
Need Improvement	13 (76,47%)	5 (41,67%)	16 (32%)	4 (22,22%)	5 (33,33%)	0	43
Optimum Mediterranean Diet	4 (23,53%)	6 (50%)	6 (12%)	8 (44,44%)	10 (66,67%)	15 (75%)	49

Table 2. Weekly dietary frequency in celiac children (expressed as a percentage).

Food	More than 4 Times	2 to 3 Times	Less than Once
Maize	75 (84,26%)	10 (11,23%)	4 (4,4er9%)
Sorghum	37 (86,04%)	4 (9,30%)	2 (4,65x%)
Rice	72 (54,45%)	50 (37,88%)	10 (7,57%)
Flour	22 (16,67%)	12 (9,09%)	99 (75%)
Millet	26(19,69%)	33(25%)	73(55,30%)
Dried fruit	55(41%)	43(33%)	34(26%)
Dairy products	43(33%)	83(63%)	6(4%)
Vegetables	102(77%)	26(20%)	4(3%)
Fruits	76(58%)	43(33%)	13(10%)
Meat And Fish Or Eggs	99(75%)	20(15%)	14(11%)
Gluten Free Products Other Than Flour	11(9%)	6(4%)	115(87%)

Discussion

A gluten-free diet provides effective treatment for celiac disease, this diet is complex, costly and socially restrictive[9]. Gluten-free foods imported from other countries are very expensive and will never be affordable for masses, expensive and outside the reach of the general population especially for long term use. The problem can be remedied by the accurate labeling of food products. Unfortunately, adequate food labeling laws do not exist in Morocco, the same situation was cited in Pakistan[10]. In Slovakia like other European countries, the situation is different health insurance companies are covering gluten-free products approximately from 60 % of the price (flour, pasta, raw material) to 5-30 % (ready baked bread, additional gluten-free cookies) and Gluten-free products have to be registered and approved as gluten-free by official laboratory examination. [11]

In Morocco, a gluten-free diet poses several other challenges, such as adhering to a balanced diet using the available alternatives. The population studied shows that it has very few participants who cannot balance their diet while the rest follow an optimal diet or need to improve their diet. This population uses naturally gluten-free alternatives like maize millet sorghum and rice. However, children and adolescents in other countries, show low adherence to the Mediterranean diet despite the availability of gluten-free product 4.2% in Spain[4], 27% in Greece[12] and between 23,0% and 33,0%.[13,14] According to a study conducted in Italy on 162 children between 9 and 12 years in the Autonomous Community of Madrid, the rate of children in optimal diets (37.12%) was closer to ours (37.5%)[5]. However, the celiac children's with optimal adherence to their diet composed mainly of food of plant origin (fruits, vegetables and cereals (maize and sorghum)) the gluten-free diet can also induce nutritional imbalances and the eating habits and the composition of the food[15].

Conclusion

Patient information and education remains a cornerstone in the management of any disorder to individuals and families with celiac disease through programmes of awareness, advocacy and education, Gluten-free foods imported from foreign countries are very expensive and will never be affordable for masses because they are more expensive than their regular counterparts. Using local products to make meals for celiac patients can help effectively in improving their well-being and overall health for the population studied. Consequently, these celiac patients manage to meet their nutritional needs in an acceptable way.

Stress, Stress Coping, Social Support, Generativity and Subjective Well-being in the Middle-Aged People

HaeKyung Chang[1], Jung Nam Sohn[1]

[1]Professor, Department of Nursing, Hanseo University, Seosan, Republic of Korea

Abstract

Purpose: This study was aimed to investigate stress, stress coping, social support, generativity and subjective well-being in the middle-aged people, to confirm the factors that affected subjective well-being so as to find out the relative importance of variables.

Method: The subjects in this study were 204 middle-aged men and women from 40 to 59 years old living in two cities in Seoul and Chungcheongnam-do and data were collected from them. The data were analyzed using descriptive statistics, Pearson's correlation coefficient and stepwise multiple regression using the SPSS 22.0 program.

Results: Mean score of subjective well-being was 3.36 point. Subjective well-being showed negative correlations with stress and avoidance among coping method of stress while positive correlations with social support seeking and problem-solving, social support and generativity. Upon the results of multiple regression analysis, social support (β=.0.37, p<.001), generativity (β=0.31, p<.001), stress (β=-0.26, p<.001) and problem-solving (β=0.16, p<.001) were shown as the influencing variables on subjective well-being with 72.5% of explanatory power for these four variables.

Conclusion: This study investigated the factors to affect the subjective well-being of the middle-aged using multiple variables, which will be used as the basic data when the nursing intervention programs are developed.

Keywords: *Stress, Coping, Social support, Generativity, Subjective well-being.*

Introduction

While life expectancy of Korean in 2015 is 82.1 years old, healthy life expectancy considering the qualitative aspects of health is 73.2 years old, showing about 10 years gap. It is urgent to establish the preventive system for health management to extend the physical and mental healthy life expectancy in the middle-aged people.[1] They experience multiple times of crisis socially or at home due to the anxiety on weakened physical and mental health, aging and retirement; burden to adapt to the multiple social changes; and burden to achieve the tasks in the development stage that should play a productive role in the society or at home. Crisis in the middle aged may cause multiple types of stresses, which develops the mental and psychological problems and threatens well-being.[2] Since stress does not cause the serious outcomes by itself but varies according to the individual ways of recognition and responses,[3] nursing interventions are required by the ways of coping stress.

Psychosocial developmental tasks in the middle aged are generativity versus stagnation which should be solved in each development stage. When the crisis of each stage overcomes, it becomes a new momentum. Generativity is a degree of individual inner development

e-mail: jnsohn@hanseo.ac.kr

in terms of identity, meaning the degree of maturity in the psychosocial adaptation in the middle aged.[4] Generativity is a core element that makes him or her feel positively and evaluate his or her life meaningful and valued one and it generates the optimistic attitudes to the changes on him or her to empathize the positive aspects.[5]Generativity is a concept existing in the individual but it is established upon the outcome of seamless interactions with social environment. Acknowledging the social support system or support of resources in the social relations can enhance the psychological well-being and generativity.[6]

As stated above, coping stress works as a core mechanism to mediate the stressful incidents and adaptation and generativity is related to the well-being in the middle-aged people. Especially, subjective well-being is a comprehensive concept with emotional experiences and cognitive judgements related to life, demonstrating that social support worked as a crucial element to affect the well-being significantly.[7] To date, few studies had been conducted on the subjective well-being in view of nursing and no study was found on the integrative approach to the factors to affect the subjective well-being especially in the middle aged. Hence, this study is intended to seek the nursing interventional plans to enhance the quality of life in the middle-aged people by investigating the factors to affect their subjective well-being using multiple variables.

Method

Subjects: The study subjects were randomly sampled among the middle-aged men and women from 40 to 59 years old who were living in Seoul and a city in Chungcheongnamdo. The minimum sample size of this study was calculated to be 184 under the conditions of modest effect size with .15, significance level with .05 and 12 predictors to secure the statistical power with 95% for correlation and regression analysis using G*Power 3.12 Program. Considering 20% of dropout rate, 221 copies of questionnaires were distributed and 204 copies were included as the final analysis subjects.

Instruments:

Stress: KPSS-10, a Korean version of Perceived Stress Scale (PSS) developed by Cohen et al.[8] was used in this study. It includes a total of 10 questionnaires with 5-point scale meaning higher score as higher perceived stress. Cronbach's α was found as .78 in this study.

Stress coping: Shin and Kim's[9] Korean Coping Strategy Indicator was used as a measurement tool in this study. It consists of 3 elements with a total of 33 3-point scale questionnaires. Cronbach's α was found as .87.

Social support: A Korean version of Multiple-dimensional Scale of Perceived Social Support (MSPSS) developed by Zimet et al.[10] was used. This tool consists of 12 5-point-scale questionnaires meaning higher score as higher degree of social support. Cronbach's α was found as .94.

Generativity: Generativity Index for the Middle-Aged developed by Lee & Lee[6] was used. It consists of 27 5-point-scale questionnaires meaning higher score as higher degree of generativity. Cronbach's α was found as .94.

Subjective well-being: Index of subjective well-being developed by Bak and Hong[11] was used. It consists of 30 questionnaires from 'never' for 1 point to 'very likely' for 5 point, meaning higher score as higher degree of subjective well-being. Cronbach's α was found as .95.

Data Collection: Data were collected from September to December 2019. The data collection was performed from the subjects of middle-aged men and women who visited community social gatherings, sports centers, shopping centers and so on by the investigator. In addition, written informed consents were prepared to participate in the study voluntarily after being informed on the study purposes and intentions.

Ethical Consideration: Anonymity and confidentiality for the selected study subjects were promised after informing the study purposes and intentions and they were informed to be allowed not to answer the questions if they are reluctant to expose the private information. Also, they were informed to stop or withdraw their consents if they do not want to participate in the study at any time. The collected data will be stored in the locked personal cabinet for 3 years after the completion of the study and then they will be discarded.

Data Analysis: Collected data were processed using SPSS/WIN 22.0 program. Frequency, percentage, mean and standard deviation were calculated for the general characteristics of the subjects, stress, coping stress, social support, generativity and subjective well-being. t-test, ANOVA and Scheffé test as a post-hoc analysis were performed on the difference of subjective well-being in the middle-aged by the general characteristics.

In addition, multiple regression analysis was performed to investigate the factors to affect the subjective well-being of the subjects.

Results

General characteristics of subjects: Mean age of the subjects was 47.66(±5.31) years old and 40 to 49 years old group was the most among these with 125 persons (61.3%). In terms of sex, females were more with 104 (51.0%) than males. University graduates were the most with 141 (69.1%); 154 (75.5%) had their spouses; 106 (52.0%) had no religion; and 172 (84.3%) had occupations. With respect to the economic status, 140 (68.6%) answered as 'middle' .

The degree of Stress, stress coping, social support, generativity and subjective well-being of the subjects: Means scores of stress; social support seeking, problem-solving and avoidance among stress coping; social support; generativity; and subjective well-being were 1.83(±0.48); 1.77(±0.44); 2.16(±0.41); 1.64(±0.36); 3.29(±0.57); 3.46(±0.77); and 3.36(±0.56); respectively (Table 1).

Table 1: The degree of Stress, stress coping, social support, generativity and subjective well-being (N=2)

Variables	Mean	SD	Min	Max
Stress	1.83	0.48	0.50	3.20
Social support seeking	1.77	0.44	1.00	3.00
Problem solving	2.16	0.41	1.09	3.00
Avoidance	1.64	0.36	1.00	2.64
Social support	3.29	0.57	1.48	4.78
Generativity	3.46	0.77	1.00	5.00
Subjective well-being	3.36	0.56	1.60	4.73

Difference of subjective well-being according to the general characteristics: For the difference of subjective well-being according to the general characteristics, significant difference was found by economic status (F=22.48, p<.001). Those who answered 'middle' for the economic status showed higher level of subjective well-being than those who answered 'low' or 'high'.

Correlations among stress, coping stress, social support, generativity and subjective well-being of the subjects: Subjective well-being of the subjects showed negative correlations with stress (r=-0.65, p<.001) and avoidance among coping stress (r=-0.40, p<.001), while it showed positive correlations with social support seeking (r=0.41, p<.001) and problem-solving (r=0.43, p<.001) among coping stress; social support (r=0.74, p<.001); and generativity (r=0.73, p<.001). As the scores of stress and avoidance were lower and those of social support seeking, problem-solving, social support and generativity were higher, the scores of subjective well-being were higher (Table 2).

Table 2: Correlations among stress, coping stress, social support, generativity and subjective well-being

Variables	Stress	Social support seeking	Problem solving	Avoidance	Social support	Generativity
	r (p)	r (p)	r (p)	r (p)	r (p)	r (p)
Subjective well-being	-0.65 (<.001)	0.41 (<.001)	0.43 (<.001)	-0.40 (<.001)	0.74 (<.001)	0.73 (<.001)

Influencing factors on subjective well-being of the subjects: Upon the results of multicollinearity test before conducting regression analysis, the range of Variance Inflation Factor (VIF) of all the variables was 1.102-1.475. Durbin-Watson stat to check the independency of error terms showed 2.177 satisfying

the hypothesis of independency. To confirm the factors to affect the subjective well-being, economic status which showed the significant difference among general characteristics was switched into a dummy variable and 7 variables were put in including stress, coping stress (social support seeking, problem-solving and avoidance), social support and generativity. Results of the stepwise regression analysis were social support (β=.0.37, p<.001), generativity (β=0.31, p<.001), stress (β=-0.26, p<.001) and problem-solving (β=0.16, p<.001), demonstrating explanatory power of these four variables with 72.5%. The biggest influencing variable was social support among these (Table 3).

Table 3: Influencing factors on subjective well-being

Variables	B	SE	β	t	p
Intercept	2.43	0.22		11.14	<.001
Social support	0.27	0.04	0.37	6.94	<.001
Generativity	0.30	0.05	0.31	5.74	<.001
Stress	-0.30	0.05	-0.26	-5.68	<.001
Problem solving	0.26	0.06	0.16	4.13	<.001
F=135.02, p<.001, Adj **R2** =.725					

Discussion

Mean value of subjective well-being of the subjects was 3.36 points among its range from 1 to 5 points in this study. In Heo and Son's study[12], psychological well-being scores were 3.45 points and 3.42 points in the adolescent and middle-age periods, respectively. For subjective well-being by general characteristics, significant difference was found in the economic status.

Praag, Frijters, & Ferrer-i-Carbonell[13] reported subjective well-being meant overall satisfaction in occupation, economy, housing, health, leisure, environment and so on, which supports the results of this study. In addition, an early study on well-being showed low impact of demographic variables on the subjective well-being, which is consistent with the results of this study.[14]

Upon the results of correlations between subjective well-being and other variables, higher subjective well-being scores were rated as the scores of stress and avoidance were lower and those of social support seeking, problem-solving, social support and generativity were higher. Middle-aged period is exposed to multiple stresses which cause mental and psychological problems and threaten well-being. It was reported that social support at this timefunctioned as a buffer to assist to respond and adapt to the stressful situations and it was related to psychological well-being,[15] which supports the results of this study. Also, generativity was related to subjective well-being,[16] which is consistent with the results of this study.

To find out the factors to affect subjective well-being, a total of 7 variables including economic status, stress, coping stress (social support seeking, problem-solving and avoidance), social support and generativity were put in to perform the stepwise regression analysis, demonstrating the significant variables with social support, generativity, stress and problem-solving. The explanatory power of these four variables was 72.5%. The biggest influencing variable among these was social support, which is consistent with the study result that psychological well-being was higher as the individual perceived level of social support system or resources was higher in the social relation.[7]

Generativity had been reported to be related to psychological well-being, self-esteem and life satisfaction and to feel subjective well-being in the course to acquire generativity, which supports the results of this study.[16] Also, stress can be predicted as an influencing variable on subjective well-being since the level of subjective well-being varied by the negative emotional experiences such as stress.[11] Lastly, problem solving among coping stress showed as an influencing variable on subjective well-being. Because no study had been conducted to confirm coping stress affected subjective well-being, it cannot

compare directly. However, considering the report that problem-solving lessened the stress level directly by changing the stress incident,[17] coping stress as a concept to apply the adaptation process of the human-being[18] can be predicted as an active measure to cope with stress.

Based on these results, active problem-solving method are required on the stress to enhance the subjective well-being in the middle-aged people and information and system should be established to be able to use the local community infrastructure in the formation of identity and strengthening support system for the middle-aged.

In addition, to allow the new meaning of life in the middle-aged people, active process is needed to experience well-being by themselves such as establishment of generativity and physical and mental health enhancement to prepare old age, moreover, to reorganize and understand it for integrative life from middle-age to old-age.

Conclusion

In this study, social support, generativity, stress and problem-solving were significant predictors as influencing factors on the subjective well-being in the middle-aged people and their explanatory power was 72.5%. Therefore, it is required to establish social support system, develop generativity and seek active problem-solving-centric coping for subjective well-being in the middle-aged. This study has the meaning of integrative approach considering multiple variables to provide nursing interventions so as to enhance the subjective well-being in the middle-aged. However, it has the limitation to generalize the study results since this study was conducted by random sampling from middle-aged men and women who lived in certain areas.

Associated Factors between Health Literacy (HL) and Results (eGFR, HbA1c) for Delayed - Progression of Kidney Disease in Type 2 Diabetic Patients The Northeast Thailand

Issaree Padphai[1], Pannee Banchonhattakit[2], Sirirat Anutrakulchai[2]

[1]Faculty of Public Health, [2]Associate Professor, Dr, Faculty of Public Health, Khon Kaen University, Thailand

Abstract

Background: The Northeast Thailand the prevalence of kidney disease in type 2 diabetic patients and death from diabetes is higher than in other regions.

Aims: 1) To study the morbidity of kidney disease in stages of type 2 diabetic patients the northeast. 2) To study associated factors between health literacy (HL) and good lab in type 2 diabetic patients the northeast.

Setting and Design: This study uses a cross-sectional analytical research.

Method and Material: A total of 1,325 type 2 diabetic patients, aged 18 and over, were selected by the multi-stage stratified cluster random sampling and collecting data using questionnaires.

Statistical analysis: Descriptive statistics Including the distribution of frequencies, percentages, mean and standard deviations. Data were analyzed using statistical generalized linear mixed model (GLMM).

Results: It was found that most of the 1,325 samples had a mild of eGFR in the second phase, 38.34%, there were 85.36 percent for the poor lab and data without using herbs, normal creatinine. And included cognitive skills, self-management skills and decision skills. Have associated with good lab with statistical significance at the level of 0.05.

Conclusion: Type 2 diabetic patients Irregular glomerular filtration rate found can be found up to almost two-thirds and results for poor lab of 2.5 out of 3, with health literacy at a low level.

Keywords: *Results (eGFR, HbA1c),Diabetes, Kidney disease, Type 2 diabetic patients and Health literacy.*

Introduction

Diabetes is a chronic disease that is a major public health problem and is likely to increase steadily. In 2015, there are 415 million people worldwide with diabetes and expected to increase to 642. Million people in the year 2040.[1] Kidney disease is increasing steadily. In 2015 around the world, the prevalence of kidney disease is 11.0 percent - 13.0 or 200 million people.[2,3] In the United Kingdom and Canada It is found in 25 percent and is higher than 40 percent in the United States. Diabetic nephropathy is the main cause of kidney replacement therapy in United Kingdom[4] and 39.7 percent of the prevalence of kidney disease in type 2 diabetes patients in the United States.[5] Poorly controlled diabetes can accelerate the progression of kidney disease at all stages of diabetes. Which increases the cost For maintenance including high-cost procedures such as regular dialysis.[6] The prevalence of kidney disease in Bangkok. Northern and northeastern regions are higher than the central and southern regions.[7]

The rate of kidney disease, which is caused by

Corresponding Author:
Pannee Banchonhattakit
Associate Professor, Dr., Faculty of Public Health, Khon Kaen University, Thailand
e-mail: panban@kku.ac.th

diabetes, is increasing every year and the problem of kidney disease from diabetes is recognized as a major problem. The most common cause of kidney disease is 49 percent and Type 2 diabetis is the leading cause of kidney disease worldwide. Is a significant problem in both developing and developed countries and is related to mortality Illness and medical expenses and patients still have a low quality of life.[8] In Thailand, 7.6 million kidney disease patients, of which end stage renal disease (ESRD) is diagnosed, require more than 70,000 dialysis or abdominal dialysis, causing suffering. With patients And the government is responsible for the annual medical expenses of 10,000 million baht[6]

And from the report of the Bureau of Non-Communicable Diseases, Department of Disease Control, Ministry of Public Health 2017, the mortality rate with diabetes increases every year. And the northeastern region, which is region 7, 8, 9 and 10, has higher mortality than other regions.[9] National Health Security office reported that the northeast region has a higher prevalence of kidney disease in type 2 diabetic patients than other regions.[10]

Objective:

1. To study the morbidity of kidney disease in stages of type 2 diabetic patients the northeast.
2. To study associated factors between health literacy (HL) and results (eGFR, HbA1c) for delayed - progression of kidney disease in type 2 diabetic patients the northeast.

Patients and Method

Cross sectional analytical research. Data were collected by questionnaires. During August - November 2019, the population used in this study with type 2 diabetic patients. Came to check in the diabetes clinic of the hospital in the northeastern region and calculate sample size by using the Hsieh et al. (1998)[11] population proportion formula. Sample size adjustment using a sample size calculation formula for studies using Multiple logistic regression to analyze data by adjusting the relationship between independent variables with the Variance Inflation Facor: VIF (Hsieh et al., 1998)[9]. There fore, the researcher obtained a sample size of 1,325 people and used Inclusion criteria, type 2 diabetic patients who have been diagnosed by doctors, aged 18 years and older. And willing to answer the questionnaire.

The multi-stage stratified cluster random sampling technique, in which the northeastern region has 4 regions, randomly selected hospitals from each health zone, 2 hospitals, Both community hospitals and hospitals in the city. A total of 8 hospitals and randomized type 2 diabetic patients. From the diabetes clinic Outpatient department In the hospital that can be chosen at random

The research instrument is self-Administered questionnaire and health literacy by the researchers who integrated the concept of Nutbeam (2008)[12] consists of 6 skills which are access skill, cognitive skill, communication skill, self- management skill, media literacy skill and decision skill. Then the questionnaires were presented to 5 experts to examine the content validity and then calculate the relative index between the question and the objective to get the value of 0.82. Diabetes Clinic Roi Et Hospital, consisting of 30 people, due to their similar characteristics to the sample group, examining the Reliability of Cognitive skill in 10 items. by kuder-richardson 20: KR20 with the difficulty classification r. 0.61. Health literacy questionnaires were access skill, communication skill, self-management skill, media literacy skill and decision skill equal to 0.80, 0.81, 0.79, 0.78 and 0.77.

Descriptive Statistics: Frequency distribution, Mean percentages and Standard deviation regarding general data, clinical data, health literacy levels, results (eGFR, HbA1c) for delayed - progression of kidney disease. Analyze variables to explain the associated between variables. Various affecting the results (eGFR, HbA1c) for delayed - progression of kidney disease (good lab). For data analysis, the categorical variable has a dichotomous variable, which is the need to modify practice group, the results group (eGFR, HbA1c) for delayed - progression of kidney disease poor level (Poor lab).And good behavior groups. Is the Results group (eGFR, HbA1c) for delayed - progression of kidney disease good level (Good lab), which is the Outcome of the study. Data were analyzed using Generalized linear mixed model (GLMM) statistics and 95% CI Confidence.

Results

1. General data of a sample of 1,325 people, mostly 66.87% female, 55.17% over 60 years old, body mass index overweight 74.79%, dual family status 78.04%, primary school education percentage 82.65% of the current occupation is agriculture, 44.30%, Duration of diabetes is in the range of 6 years and over 88.23%.Most do not smoke, 88.83

percent. Most do not drink alcohol, 86.72 percent. Most non-steroidal anti-inflammatory drugs do not. 80.60%. Most of them do not use herbs, 69.43 percent. And most of the internet use is less than 4 hours per day 94.87%

2. Clinical data from the latest health examination The sample consisted of 1,325 people. Most blood pressure is usually less than 140/90 mmhg 84.23%. Urine albumin is higher than 30 mg/dl 50.42%. Normal serum creatinine is less than or equal to 1.2 mg/dl 86.57%. Cholesterol LDL greater than 100 mg/dl 78.64 percent.

3. Number and percentage of the subjects have health literacy levels access skills were at a moderate level 53.13%, cognitive skills were at a low level 58.79%, communication skills were at a low level 58.64, self-management skills were at a moderate level 55.09%, Media literacy skills With a low level of 60.68 percent, media literacy skills with a low level of 60.68 percent and decision skills with a low level of 57.66 percent

4. The glomerular filtration rate (eGFR) and hemoglbin A1c (HbA1c) good lab and poor lab due to studies The objective is to study the rates of kidney disease in different stages of type 2 diabetic patients. Northeast region It was found that the number and percentage of most samples had the HbA1c level higher than 7 mg/dl 85.36 percent. And the glomerular filtration rate stage 2 (eGFR 60 - 89 ml/min/1.73m^2) 38.34%, most of the samples had results for delayed - progression of kidney disease, 85.36% Poor lab level as follows shown in table 1.

Table 1: Number and percentage of good lab and poor lab of the sample. (n=1,325)

eGFR and HbA1c	Number	Percentage
1. HbA1c (mg%)		
Normal (less than or equal to 7)	194	14.64
High (more than 7)	1,131	85.36
2. Glomerular filtration rate (eGFR)(ml/min/1.73m²)		
Stage 1 with normal or high GFR (eGFR ≥ 90)	486	36.68
Stage 2 mild CKD (eGFR 60 - 89)	508	38.34
Stage 3A moderate CKD (eGFR 45-59)	186	14.04
Stage 3B moderate CKD (eGFR 30-44)	134	10.11
Stage 4 severe CKD (eGFR 15-29)	11	0.83
Stage 5 end stage CKD (eGFR <15)	-	-
3. Results for Delayed - Progression of Kidney Disease		
Good lab (eGFR ≥ 90, HbA1c ≤ 7mg%)	194	14.64
Poor lab (eGFR ≤ 90, HbA1c > 7mg%)	1,131	85.36

5. The odds ratio analysis between the general data associated with the good lab showed that age, body mass index, education level, occupation, duration of diabetes drinking alcohol, the use of non-steroidal anti-inflammatory drugs, the use of herbs and using the internet per day correlated with the results of good lab and statistically significant at the level of 0.05.(Simple logistic regression)

6. The study found that the sample group had the good lab 14.64 percent (95% CI 12.73: 16.54). And from the analysis of the crude odds ratio between the clinical results that are in relation to the results of a good lab for delayed - progression of kidney disease, the urine albumin and serum creatinine associated with good lab and statistically significant at the level of 0.05. (Simple logistic regression)

7. Analysis of the odds ratio associated between health literacy and good lab results showed that access skills, cognitive skills, communication skills, self-management skills, media literacy skills and decision skills. Have associated with good lab with a statistical significance of 0.05

8. The analysis of factors associated to the results of

a good lab when considering the effects of other factors, such as region level and hospital level using (Generalized linear mixed model (GLMM) and Confidence at 95% CI). The results showed that age, body mass index, duration of diabetes, the use of herbs, serum creatinine, cognitive skill, self-management skilland decision skill were related to the results of a good lab . With statistical significance at the level of 0.05 as shown in Table 2.

Table 2: Showing odds ratio and 95% CI between factors associated with good lab from GLMM analysis

Factors	Number	%Good lab	Crude OR	Adjusted OR	95%CI	p-value
1. Age (years)						
Less than 45	66	27.27	3.71	2.31	1.08 to 4.93	0.030
45 – 60	528	20.64	2.57	1.72	1.11 to 2.66	0.015
More than 60	731	9.17	1			
2. Body mass index (kg/m2)						
Less than 18.5	103	14.56	1.50	2.54	1.28 to 5.05	0.007
18.5 – 22.99	231	33.77	4.49	4.16	2.73 to 6.36	< 0.001
Greater than or equal to 23	991	10.19	1	1		
3. Duration of diabetes (year)						
Less than or equal to 5	1,169	23.72	2.00	2.85	1.66 to 4.91	< 0.001
6 years and older	156	13.43	1	1		
4. The use of herbs						< 0.001
Use	405	6.67	1	1		
Not use	920	18.15	3.10	2.31	1.40 to 3.82	
3. Serum creatinine (mg/dl)						0.006
Normal (less than or equal to1.2)	1,147	16.04	3.20	2.78	1.34 to 5.76	
High (more than 1.2)	178	5.62	1	1		
4. Cognitive skill						
Low	779	8.99	1	1		
Average	431	19.26	2.41	2.15	1.44 to 3.22	< 0.001
High	115	35.65	5.61	3.23	1.82 to 5.75	< 0.001
5. Self-management skill						
Low	429	7.93	1	1		
Average	730	16.58	2.30	1.81	1.12 to 2.92	0.015
High	166	23.49	3.56	3.48	1.81 to 6.70	< 0.001
6. Decision skill						
Low	746	11.13	1	1		
Average	456	16.67	1.59	2.28	1.19 to 4.36	0.012
High	105	31.43	3.66	3.81	1.68 to 8.62	< 0.001

Discussion

The study found that the results (eGFR, HbA1c) for delayed - progression of kidney disease good level (Good lab)of the sample, only a percentage 14.64 (95% CI 12.73 : 16.54) and patients with type 2 diabetes abnormalities in the glomerular filtration ratecan be found in nearly two-thirds, consistent with Bunloet et al., 2018. That is, when the number of patients with diabetes increases, the kidney disease from diabetes will increase respectively and the results (eGFR, HbA1c)for delayed - progression of kidney disease to a poor level of 2.5 out of 3.

Majority find that health literacy for delay - progression of kidney disease is low and the results

for delayed – progression of kidney disease to a good level there is a statistically significant associated with those younger than 45 years old, body mass index 18.5–22.99kg/m^2, duration of diabetesis less than or equal to 5 years, not using herbs, normal serum creatinine is less than or equal to 1.2,cognitive skill, self-management skill and decision skill and high level of health literacy affects delayed-progression of kidney disease behavior and results (eGFR, HbA1c) for delayed - progression of kidney disease good level (Good lab).

This study has limitations in data collection. Which is data collection using questionnaires In many patients, the complete lack of clinical examination results is recorded. And is an elderly person which causes problems in reading questionnaires Which will not be brought to participate in this study

Summary of this study shows patients with type 2 diabetes. In the northeastern region, behaviors should be adjusted to delayed - progression of kidney disease. Therefore, it is able to apply health literacy to delayed-progression of kidney disease to improve health services. Increase screening policies for at-risk groups for complications and as a guideline for management of education systems for target patients.

Staging Characteristics of Prostatic Cancer Patients in Department of Urology Dr. Soetomo Surabaya

Nando Reza Pratama[1], Reny I'tishom[2], Wahjoe Djatisoesanto[3]

[1]Student of Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, [2]Department of Biomedicine, Faculty of Medicine, Universitas Airlangga, [3]Department of Urology Dr Soetomo, Faculty of Medicine, Universitas Airlangga

Abstract

Background: Prostate cancer is ranked 4th as the leading cause of death of cancer in men in Indonesia. Most of the patients in developed countries are diagnosed at an early stage while in Indonesia they come at an advanced stage. It is important to know the yearly staging distribution throughout the hospitals, including General Academic Hospital Dr. Soetomo, for the epidemiology recording. As a result, the strategy in the treatment can be evaluated further according to this data.

Objective: This study aims to know the earlier diagnosis characteristics of staging of prostate cancer in patients of General Academic Hospital Dr. Soetomo Surabaya.

Method: This study is an observational descriptive study with a retrospective design. The data in this study were taken from the medical records of prostate cancer patients in General Academic Hospital Dr.Soetomo from 1 of March 2014 to 31 of May 2018 which was selected according to inclusion and exclusion criteria, resulting to 75 patients.

Results: Every year, stage IV and III are the most common findings. In total, the number of prostate cancer staging are dominated by stage IV (n=39) followed by stage III (n=35). Abnormal in clinical exanimations are enlarged prostate (n=26), abnormal prostate surface (n=28) with mostly are positive nodules (n=25) and hard consistency (n=24); abnormal PSA level examination (n=71) with mostly are in the range of > 100 ng/mL (n=33); and on biopsy results, grade 5 (n=40) is the highest.

Conclusion: The number stage III and stage IV are the most common findings each year with the highest total number is stage IV.

Keywords: *Stage Presentation, Prostate Cancer, Prostate.*

Introduction

The number of prostate cancer cases worldwide in 2012 was ranked 2nd, around 1.112.000 of cases with 307.000 deaths[1]. In Indonesia, prostate cancer is the 4th in all cancer cases. In 2014, there were 13,663 cases of prostate cancers with 9,176 deaths[2]. Prostate cancers have divided into epithelial tumours, neuroendocrine tumours, mesenchymal tumours, hematolymphoid tumours and miscellaneous tumour; being adenocarcinoma (included in epithelial tumour) is the highest incident rate[3,4]. The population who have risk factors of prostate cancers are more prone to develop prostate cancer[5].

The diagnosis of prostate cancer must be conducted through biopsy. Prostate Specific Antigen (PSA)> 4 ng/mL and/or abnormality in Digital Rectal Examination

(DRE) are indications for biopsy. Biopsy is taken to determine the pathologic characteristics by means of Gleason score. After biopsy, CT scanis used to determine whether it is metastatic or not. The whole examination results are used to determine the staging[6,7].

It is important to know the staging distribution of prostate cancer for monitoring and evaluation of prostate cancer incidence in order to increase awareness on prostate cancer. However, what is the statistical description of prostate cancer in General Academic Hospital Dr. Soetomo is still unknown. Some cancer patients who are diagnosed with a higher stage has a less chance of survival. It may be caused by the patients themselves who are not aware of the symptoms that they have, the primary care doctors who do not suspect cancer for such symptoms, or the suspected cancer patients are not quickly referred and treated correctly in secondary care[8].

Samples and Method

This study is an observational descriptive study with a retrospective design.

Collection of Medical Records: The data were medical records taken from Communication and Information Technology Installation (IT), central medical record and for Cancer Development & Services Center (PPLK) sections. The medical records of prostate cancer, ICD-10: C.61, patients in General Academic Hospital Dr.Soetomo were from 1 of March 2014 – 31 of May 2018. Samples were taken by *total sampling* from both outpatients and hospitalized patients.

Selection of Medical Records: The inclusion criteria were all medical records of prostate cancers, ICD-10: C.61. Then, the data that has not either PSA, Biopsy Results, or TNM-staging were excluded, resulting to 75 medical records.

Staging and Risk Group Determination: These data were inputted and processed in Microsoft Excel 2016. The data of PSA and TNM-staging were used to obtain Staging Distribution based on AJCC eighth edition and Risk Group based on National Comprehensive Cancer Network (NCCN) 2018 guideline.

Results

Demographic Data of the Patients:

Number of Patients: There were 75 patients from 2015 to 2018 that the number increases each year being 2015 (n=9) was the lowest, 2016 (n=18) and 2017 (n=18) were similar and 2018 (n=30) was the highest.

The age distribution: Most of the patients were aged 60-69 years (n=38) and there was no patient aged 30-39 years. The data had the mean of 63.64 (SD ± 9,41) years and the median of 63 years. The youngest patient was 23 years and the oldest patient was 83 years being the data had the range of 23-83 years.

The patient's education distribution: The education of the patients was mostly Senior High School (n=38), followed by Elementary School (n=14) and Junior High School (n=8). There were patients not finished their education from Elementary School (n=2). 8 patients were higher degree than Senior High School, diploma (n=3) and bachelor's degree (n=5). 5 patients were written others.

Clinical Examination Findings: There were five variables in this section—DRE, PSA, biopsy, staging and risk group.

Digital Rectal Examination:

Table 1: Enlargement, surface and consistency of prostate from DRE

DRE Findings	Number (n)	Percentage (%)
Enlargement		
Enlarged	26	34.66%
Not Enlarged	21	28.00%
No data	28	37.33%
Nodularity		
Lumpy	3	4.00%
Nodule +	25	33.33%
Nodule -	29	38.67%
No data	17	22.67%
Consistency		
Hard	24	32.00%
Soft	24	32.00%
No data	27	36.00%

The abnormality found was enlarged (n=26); nodule + (n=25) and lumpy (n=3); and hard (n=24).

PSA level in blood: The level of PSA was classified into 4 level being < 4 (n=4) was normal and the others (n=71) were abnormal. The abnormal levels were in the range of 4-10 (n=6), 10-100 (n=32) and > 100 (n=33). 34 Out of 71 patients were also found abnormality in DRE.

The PSA level data has the mean of 386,44 ng/mL with the lowest level was 0.04 ng/mL and the highest level was 3781 ng/mL.

ISUP Grade Group: The biopsy result was written in Gleason score which was converted into 5 grades according to ISUP Grade Group. The most common finding was grade 5 (n=40) and the least common finding was grade 3 (n=2). There was 1 data that was written as high grade (n=1). This data could not be converted into ISUP Grade Group.

Table 2: The histopathology distribution of the prostate tissues according to ISUP Grade Group.

Grade	Number (n)	Percentage (%)
Grade 1	6	8.00%
Grade 2	8	10.67%
Grade 3	2	2.67%
Grade 4	18	24.00%
Grade 5	40	53.33%
High grade	1	1.33%
Total	75	100%

Staging and Risk Group Distribution:

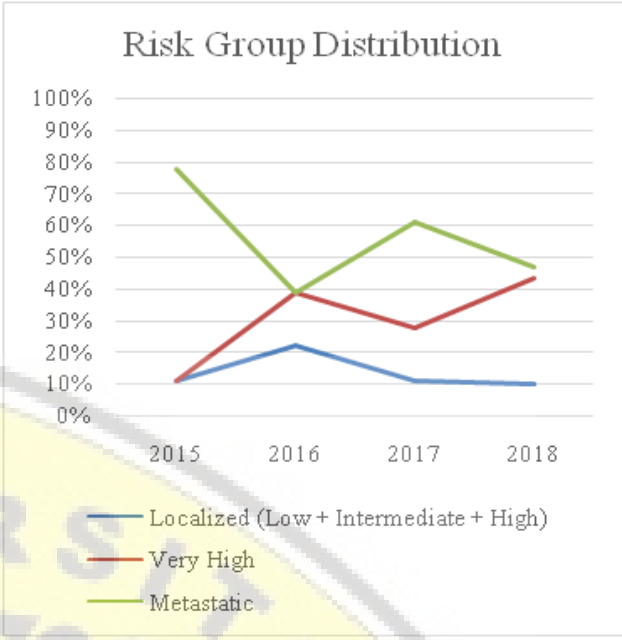
Very High	5	27.78%
Metastatic	11	61.11%
2018		
Low	0	0.00%
Intermediate	0	0.00%
High	3	10.00%
Very High	13	43.33%
Metastatic	14	46.67%
Total		
Low	0	0.00%
Intermediate	1	1.33%
High	9	12.00%
Very High	26	34.67%
Metastatic	39	52.00%

The staging distribution was grouped each year. The stage level of each year was put in table 3 and a diagram (Picture 1) to see the trend of the stage in each year. The stage was determined according to AJCC eight edition by considering PSA level, biopsy finding or Gleason score and TNM finding. The data found that in each year, stage III and stage IV were always dominating.

The risk group was determined according to NCCN 2018 based on the PSA level, Gleason score and TNM findings. The risk groups were group each year and the results were put in the table 4 and a diagram (picture 2). The risk group of low risk, intermediate risk and high risk are localized.



Picture 2: Risk group distribution of the prostate cancer patients.

Discussion

Demographic Data of the Patients: Age is one of the main risk factors for prostate cancer[9]. There were about 85% of patients diagnosed with prostate cancer aged 65 years old or more. Another research stated that only 10% of new cases of prostate cancer were patients with age less than or equal to 55 years old[10].

The youngest patient age in this research was 23 years old. This finding shows that prostate cancer can emerge at a young age. Besides age, other factors such as genetic may increase the risk, up to 40%[11]. BRCA-2 and HOXB13 mutations played a role in the emergence of prostate cancer lesions at a young age. BRCA-2 and HOXB13 mutations increased the risk of prostate cancer at <55 years old by 23 and 8 times, respectively[12].

Over time, findings of prostate cancer cases in younger age groups tend to increase. Epidemiological studies of prostate cancer cases from 1973 to 2008 showed an increase of new case of prostate cancer in the age group of 55 years old and below up to 5.7 times (95% CI: 5.0-6.7)[13]. Research on autopsy of prostate showed that 27% of 30-years-old men had cancer lesions, 40-years-old men had a percentage of 30%, while 60-years-old men had 50% and in 85-years-old men and over had 75% or more. This finding was in line with epidemiological data on the case of new cases in patients with age of <55 years old which had increased

considerably since the introduction of screening method using PSA.[12,10,13]

There were 60 patients with education level of senior high school and below. Education level affects morbidity and mortality rate in prostate cancer patients that a man with a higher level of education had a lower mortality rate[14]. This might be the reason why the risk group findings of very high and the metastasis had a large percentage.

Clinical Examination Findings: There were 37 patients with abnormality on DRE alone and 71 patients were found to have abnormal PSA level with 34 out of 71 patients had abnormality in DRE.DRE and PSA results will determine the prognosis. When an abnormality was detected only on either DRE or PSA level, the patient had a better prognosis than that of patients whose abnormality was detected on both examinations. Patients whose the abnormalities were in both DRE finding and PSA levels had a worse clinical and pathological characteristic[7].

Blood PSA levels in this research were mostly in the range of > 100.0 ng/mL (n = 33, 44.00%). There was a significant correlation between PSA and stage levels. It was reported that the results of the PSA mean value at T1N0M0 was 8.9 ng/mL; at T2N0M0 was 12.9 ng/mL; at T3-4N0M0 as 29.9 ng/mL; and at T3-4N0-3M0-1 was 317 ng/mL[15].

Of 75 patients, 6 were not written in numerical form but in the range of numbers. A total of 5 medical records were written > 100 ng/mL and 1 was written > 1000 ng/mL so that the average of PSA levels data only involved 69 patients with a result of 357.44 ng/mL. This high number was probably caused by a wide range and the presence of several outliers.

There was 1 patient whose results cannot be converted to Grade Group because the results were not written in the Gleason score, but was written in high grade according to the older classification rules. In the older classification, high grade was defined as cancer with a Gleason score of 8-10. But now, the Gleason 8 score is classified into group 4 and the Gleason score 9-10 is classified into group 5[16]. Therefore, this data cannot be determined whether in group 4 or group 5.

Stage level data in this research were dominated by stages III and IV each year. In 2015 and 2017, most patients were patients with stage IV. In 2016 and 2018, most patients were patients with stage III. In total, number of patients with stage IV (n=39, 46.67%) was greater. This means that the case of prostate cancer in General Academic Hospital Hospital Dr. Soetomo was dominated by patients with high stages.

The above results have similarities in prostate cancer research at Cipto Mangunkusuma Hospital (RSCM) and Dharmais Cancer Hospital (RSKD) Jakarta. In the research, the highest percentage was stage IV with 67.17%, followed by stage II with 28.08%, while the lowest percentage was stage I with 0.57%[15]. Data from the Indonesian Society of Urologic Oncology (ISUO) 2011 in the National Guidelines for Prostate Cancer Management Medical Services by the Ministry of Health states that 50.5% of prostate cancer patients are stage IV[17]. Unlike in US, Epidemiology of localized prostate cancer data was 77%, regional 13%, distant 6% and unknown 4%. In addition, the 5-year relative survival rate in general were 98%[18]. This shows that the health condition regarding prostate cancer in Indonesia is still poor. For this reason, policies that support health promotion efforts regarding prostate cancer need to be improved.

The classification of patient risk groups according to the NCCN 2018 criteria was divided based on the results of PSA, ISUP Grading and TNM. Low, intermediate and high-risk groups were localized; very high-risk groups were locally advanced; and metastatic groups were with the presence of N1 or M1 findings. This classification served to classify patients based on the risk of reoccurrence or development of the disease and was used as a treatment determination for prostate cancer patients[19].

Conclusion

Based on the findings of the number of prostate cancer stages, stage III and stage IV were the most common findings in each year with the highest total number being stage IV. The distribution of stages and risk groups each year fluctuated but did not show a significant decrease or increase.

Conflict of Interest: The authors declare that there is no conflict of interest in this study.

Abstracts

Health Polytechnic of Health Ministry Palu is one of the institutions that implement interprofessional education in the health sector such as midwifery, nursing, environmental health and nutrition. Interprofessional education and collaborative practices are needed by health professionals to deal with natural disasters. The flash flood disaster has hit South Dolo Subdistrict, Sigi Regency, Central Sulawesi on April 28, 2019. This study aims to describe the collaboration of the Academic Community of the Health Polytechnic of Health Ministry Palu in reducing health risks after a flash flood disaster. This study was a case study conducted in the Bangga Village of South Dolo Subdistrict from April 29 to May 2, 2019. The location of the study and informants was determined purposively. Data collection through observation and interviews of 25 students of Health Polytechnic of Health Ministry Palu, 5 lecturers, 5 families affected by disasters, Bangga Village secretary, officers of the Social Service and Sigi District Health Office, each one person. The results showed that on the first day a number of mineral water supplies, basic food needs, cooking utensils, toiletries, adult clothing, children's and baby clothing had been collected and assessments had been performed on refugee needs, refugee physical health conditions, environmental health conditions of refugee tents.

Keywords: *Interprofessional Collaboration, Disaster, Refugee, Flash Flood.*

Introduction

Floods and problems related to flooding are becoming increasingly rampant throughout the world which causes failures, infrastructure damage and epidemics every year[1]. Indonesia is a disaster-prone area. Disasters can occur due to nature or human activity. One of them is the flash flood. These conditions need mitigation efforts including help, rescue, providing temporary shelter, meeting basic needs, health services and clean water and sanitation needs [2]. Flash flood which struck five villages (Bangga, Balongga, Walanata, Omu and Tuva) in South Dolo Subdistrict, Sigi District, Central Sulawesi, resulting in severe damages.[3] The Sigi District Regional Disaster Management Agency reported since Sunday night April 28, 2019, after a flash flood and mud incident at least 500 housing units, a resident died after being washed away by flooding and 2,400 residents or 640 families forced to leave their homes and flee to more secure places[4]. Disaster events result in disaster victims having to evacuate with all limitations[5]. Health risks associated with flooding are diseases transmitted through vectors and water [6]. Following the flood, the risk of disease outbreaks such as hepatitis E, digestive diseases and leptospirosis increased, especially in areas with poor hygiene and densely populated refugee populations[7]. After the flood, related to loss of jobs, severely damaged housing, traumatic babies, children's education and poor health[8]. Research in Yogyakarta that explores the effectiveness of interprofessional education programs in the context of disaster management involves 72 medical, nursing, health and nutrition students[9].

Interprofessional competencies have to be integrated into disaster preparedness education[10] Health Polytechnic of the Ministry of Health Palu is one of the institutions responsible for interprofessional education in the health sector, such as midwifery, nursing, environmental health and nutrition.

This study aims to describe the collaboration of the academic community of the Health Ministry Polytechnic of Palu in reducing the risk of post flash flood disaster (Case study of South Dolo Subdistrict, Sigi Regency).

Material and Method

This study is a case study in Bangga Village, South Dolo Subdistrict, which was conducted on April 29 to May 2, 2019. This type of study is qualitative descriptive, where field data relies on observations, information, views and perceptions of informants. The location is specifically determined, namely the area affected by natural disasters in the South Dolo district. The selection of informants was done purposively by considering the condition/suffering of the people affected by a flash flood at the same time because they lived in the same area with the same conditions. Data collection is done through in-depth interviews. Data collection through observation and interviews of 25 Health Polytechnic of Health Ministry Palu students, 5 lecturers, 5 families affected by disasters, Bangga Village secretary, officers of the Social Service and Sigi District Health Office, each one person. Observations were made on the condition of the environment and community activities, then study documentation, namely studying documents related to flash flood. Ethical Clearance; Polytechnic of Health Ministry Palu, City of Palu, Indonesia.

Result and Discussion

The distance between the village and the capital of South Dolo Subdistrict varies, the village furthest from the sub-district capital is Jono Village with a distance of 8 km while the village closest to the sub-district capital is Bulubete and Rogo Villages with a distance of 1 Km each. Based on data from the age group in the South Dolo sub-district the productive age group reached 63.54% of the total population of the South Dolo sub-district or around 4,960 people. Demographic and socio-economic conditions, the total population of Dolo Selatan District is 15,763 people, with an area of 664.78 km^2, the population density reaches 24 people/Km^2[11]. Flash flood disaster is part of the hydrometeorological disaster which indicates a significant impact on life and property[12].The main factor of a flash flood is triggered by the intensity of extreme rain[13].

Information about the flash flood in Dolo Sigi Subdistrict was first obtained from the news[14].The participation of student executive bodies (BEM), student associations majoring in nursing, midwifery student associations, environmental health student associations and nutrition student associations, the missionary institution of As-Syifa campus, Health Ministry lecturer Polytechnic Palu strongly supports the distribution of aid to flash flood victims in Sigi. On April 29, 2019, the first step taken was the head of the Health Polytechnic of Health Ministry Palu instructing the research and community service unit, Chairpersons of the Department to disseminate flash flood information and collect assistance for victims of flash floods[15] In line with the Sendai Disaster Risk Reduction Framework 2015-2030 which states that disaster management needs to be shifted to disaster risk management rather than reactive response[16] than in the case of the flash flood disaster in Sigi, on the first day an assessment was carried out to minimize the health risks after the flash flood disaster.

The results of assessments of refugee needs, physical health conditions, environmental health conditions of refugee tents showed that on the second day bottled water supply increased, coming from donors, but there was still inequality especially for areas that were difficult to reach.Observing the physical health conditions of refugees in the field shows that refugees suffer from itching due to bathing in rivers with dirty water. Learning from the Bangladesh flood experience, In flood victims, the most common problem is fever (63.6%), followed by respiratory problems (46.8%), diarrhoea (44.3%) and skin problems (41.0%). Because of public health problems caused by flash floods and changes in weather, strategies are needed to raise awareness of potential sources of contamination and motivate preventive behaviour[17]. Observations on the health conditions of refugee tents showed that tents had been installed from the BPPD in Sigi district, as well as tents made from tarps using bamboo and wood. Learn from the Kamal study in Bangladesh that shows that poor people are very vulnerable to flooding, but also more adaptive and resilient; while middle-income households are vulnerable because they are reluctant to take any jobs and rely more on assistance, while rich households, although less adaptive, can recover from floods due to wealth[18]. Other observations in the field show that the preparedness of the Baluase Community

Health Center as the flash flood area controller is quite good.On the first day after the flash flood, health workers from the Baluase Health Center have provided services to the victims. Other Aceh research shows that there is a significant relationship between attitudes and knowledge of health workers on preparedness to face the risk of flood disasters at the Pidie Jaya Regional General Hospital[19]. Cooperation between the Village Government and BPBD Sigi is the steps that need to be taken to increase community capacity and reduce vulnerability, Learn from the results of research conducted in Aceh that disaster preparedness is one of them by setting up non-governmental organizations to deal with disasters, increasing the role of the government in policy-making to reduce disaster risk and developing disaster curricula in schools[20].Due to the sudden onset of the disaster and to the detriment of many aspects, disaster anticipation needs to be prepared. Disaster training and emergency simulation training are therefore needed to improve preparedness. The results of the Palan study (2019) showed an increase in preparedness in nursing students after counselling and emergency simulation training[21]. On a small scale, disaster problems, as well as the application of occupational safety and health in the campus environment, have not received attention, so that the risk of accidents and diseases to lecturers, education staff, students, janitors, campus visitors can still occur[22]. The results of this study also indicate problems related to lack of supply, low quality of drinking water and the existence of inequality in the supply of drinking water, an important strategic issue to be developed by the institution is increasing coordination efforts on partnerships between institutions, efforts to determine the amount of drinking water supply in accordance with the needs of the community, improving the performance of the local government to restore the trust of donors, as well as efforts to monitor the condition of the fulfilment of drinking water needs for people in need, especially vulnerable communities[23].

In relation to urban communities and the flash flood issue, Bodoque's research shows variations in people's perceptions. In particular, 60.8% of those interviewed had low-risk perceptions and low awareness (cluster 1); 24.4% had high-risk perceptions and low awareness (cluster 2), while the remaining 14.8% had high long-term risk perceptions and high awareness (cluster 3).

The characterisation of social security is very important in flash flood-prone urban areas to ensure the success of emergency management plans.[24]. Variations in the potential danger of flash flood disaster in an urban city can use the Wetness Index and the Urban Heat Index.An urban flash flood potential is disproportionate at different times of the year[25]Flood risk integration in spatial planning is also seen as a means of increasing the city's resilience to increased flood hazards[26].

Using a disaster response could improve student engagement, comprehension and perception of interprofessional collaborative practice. In the post-workshop survey, there has been an increase in understanding and perceptions of interprofessional collaboration and practice. In the pre-workshop survey, the students had a limited understanding of the collaborative practice and its importance in everyday practice[27]

They can observe role modelling at the workplace and assume that studying with other professions will help them to become more effective members of the health care team[28]. The benefits obtained from this case study in the scope of lecturers-students, students between departments, students with disaster prepared cadets, Health Polytechnic of Health Ministry Palu with health services is an application of inter-professional collaboration. According to Prihatiningsih, disaster management by the interprofessional education approach has the benefit of educating students from different backgrounds to be able to better interact and cooperate with other professions[29]. Training in participatory method is needed to link technical knowledge with everyday practice in emergency management. Lessons learned will form the basis for future interventions to prepare health professions and emergency preparedness and response programs to implement community-based emergency preparedness strategies[30].

Conclusion

Interprofessional education aims to improve teamwork and communication skills. The collaboration of the Palu Ministry of Health Polytechnic Community as a form of interprofessional education in reducing risks after the flash flood disaster is an example of a case study of a health professional to deal with flash flood disasters in South Dolo Subdistrict, Sigi Regency. From this case study, students have a number of opportunities for inter-professional education. They can observe role modelling at the workplace and assume that studying with other professions will help them become more effective members of the health care team.

Health Care Accessibility of Migrants in Border Areas of Northeast, Thailand

Nutchanun Kamonroek[1], Niruwan Turnbull[2], Savittri Rattanopad Suwanlee[3], Karl Peltzer[4]

[1]Doctoral Student in Public Health Program, Faculty of Public Health, Mahasarakham University, Maha Sarakham, Thailand, [2]Faculty of Public Health, Mahasarakham University, Maha Sarakham, Thailand, [3]Faculty of Humanities and Social Sciences, Mahasarakham University, Maha Sarakham, Thailand, [4]ASEAN Institute, Mahidol University, Nakhon Pathom, Thailand

Abstract

Access to health care among migrants groups is major concerning in Thailand. This study aimed to explore the situation of health care accessibility of migrants in the border land in the Northeast of Thailand. This quantitative survey research was conducted in 72 migrants in the border areas in the Northeast of Thailand. Collecting data was using a created questionnaires whose ever been accessed in healthcare service in the system.

The results showed that migrants, there were four nationalities comprised such Laos (77.8%), Cambodia(16.7%), Myanmar (2.8%) and stateless (2.8%) respectively. Most of them came to Thailand without the resident's visa and illegal immigrant as 73.6%. There was only only 29.6%has registered with Thai health insurance scheme which was seperated in Universal care coverage for migrant 47.6%, Social Security scheme for migrant worker 38.1% and Others 14.3%. The major problem of migrants was poor opportunity to access in health care service due to their inability to pay. In the other hands, group with health insurance system was facing to continue their right and maintaining.

In conclusion, this finding is most of the migrant workers could not access health services. Legal status has important for applying for a health management system. Obstacles to accessing the health service system due to the lack of legal status which affects various aspects of the migrant population. The Thai government should develop a system for a registration system for a migrant in the health system without regardless of legal status.

Keywords: *Healthcare access, Migrant, Border Areas, Northeast of Thailand.*

Introduction

With regards to human rights in health as international concerned due to living conditions of migrants are considered a vulnerable group with specific medical requirements. The issue of health and migration is becoming, particularly in Thailand, a recognized interested in the nation policy. Migration affects individuals physically, mentally and socially. It particularly affects the health of the migrants and everyone else around them(1). The situation of migration in Thailand during the transition to the 21st century has caused various changes. There is a major challenge for the Thai health system to provide citizens from neighboring countries with healthcare service(2). Thai policies to promote the international trade of Thailand has resulted in an increased migrant population. There werea lot of people crossing the Thai border from countries with differences in race, ethnicity, beliefs,

Corresponding Authors:

e-mail: nutchanun.kam@msu.ac.th

cultures and traditions and this movement may result in various health problems[3,4]. These might be major contagious problems, emerging and re-emerging infectious diseases, maternal and child health problems, accessing healthcare and treatment problems. Contagious diseases, especially, need careful management including information about the migrant population and planning for disease prevention[2,3,5,6].

Ubon Ratchathani is an important border province that connects three countries: Thailand, Cambodia and Laos. Consequently, there is a lot of immigration, especially illegal immigration into the province. Between 2015 and 2018 the number of migrant workers registered with the Ministry of Labor in Ubon Ratchathani was 1,951 2,850 3,315 and 3,145 for each year respectively[7]. There seems to be a general increase every year. The migrant workers' health insurance card sales from 2015 to 2018 was 3,242 cards. Some migrant workers were seasonal workers for unskilled employment but were not registered correctly with the system[8].

In Ubon Ratchathani from 2013 to 2015, the surgical treatment expenses, unable to charge 32,820,640 baht, 23,749,532 baht and 35,987,383 baht respectively [7]. Between 2016 and 2018 the Ministry of Public Health found the expenses from both in-patients and out-patients incurred by citizens without Thai nationality were as high as 6,945,271,654 baht, of which only 40 percent was able to be charged for [6]. Considering the above-mentioned health expenses, the increasing trend of migrant patients has caused the hospital to bear the burden of expenses, resulting in a financial crisis. Ubon Ratchathani Provincial Public Health Office's guidelines were to set up a budget to compensate hospitals that bore the burden of caring for migrant patients and experiencing a financial crisis, especially hospitals with areas along the borders. With a limited budget, however, it was impossible to maintain all hospitals.

In 2014, the major incidence of infectious diseases in Ubon Ratchathani was malaria. 877 patients were accounting for 47.75 per 100,000 population, of which 5.47 percent of all patients are Lao nationality. Most of them have no welfare for medical treatment. Most were found in Na Chaluai District, Buntharik District and Nam Yuen District. These hospitals have a crisis of medical expenditures because of migrants who did not have health insurance.

The allocation of healthcare professionals and various aspects of management has become inefficient [9, 10]. The situation of these migrants revealed that the solutions to the health problems of the migrants did not cover all migrant groups. All people are entitled to human rights, however, the legal restrictions affect access to healthcare. The plans to solve the inefficient health problems regarding migrant workers complied with the policies set by the Thai government. The Ministry of Public Health has policies that link to complex health systems and migration by establishing a guideline for the health of migrants using the factors determining social health (Social Health Determinant: SDH). Therefore, to focus on the health of the migrant workers dynamically, this paper investigates the circumstances, context and difficulties in accessing the healthcare system.

The objective of this study is to investigate the situations access of migrants to healthcare systems in the border areas in the Northeast of Thailand

Material and Method

The research applied quantitative studie. Collect the data in 72 migrants whose ever been access health care service in 6 months in Ubon Ratchathani Province. Data were collected from October 2016 -April 2017.

The questions developed from the literature review and synthetic reviewapproach from previous topicfrom 6 sources [10, 13-17]with comprehensive information of two main factors, which included 1) demographic data with regarding to sex, age, time for stay in Ubon Ratchathani, nationality, education, earn per month, type of immigration, cause of migration and intended duration of stay. 2) Accessing to health service of migrants regarding health insurance, type of health insurance, pay for migrant health insurance, the distance between the hospital and the house, traveling to the hospital, payment of medication and suggestion for improving services, etc. 3) The attitude of migrants toward the quality of health care services regarding the quality of the health service, health work forces, place, technology, medicines and expert health professionals.

The questionnaire was tested for content validity by 5 experts, with the straightness of 0.89 and the reliability of the Cronbach alpha coefficient equal to 0.92.The descriptive statistics analyzed to demographic data and health service access.

Ethical Consideration: The study was obtained from Mahasarakham University Research Ethics

Committee (PH 020/2016). Written informed consent was attained from all study participants.

Finding:

Demographic Characteristics: The results showed the migrants were mostly female (59.7%); aged 33-49 years old (37.5%); Laotian (77.8%), Cambodian (16.7%), Myanmar (2.8%) and stateless (2.8%). Mostly, they were uneducated (55.6%) and average earn 6,136.11 bath/month. Type of immigrations are undocumented (without the resident's visa and illegal) (53.6%), with documents (23.6%) and unresponsive (2.8%). Cause of migrations mostly as political conflict based immigrant (62.5%), family-based immigrant (15.3%), employment-based immigrant (12.5%) and others (9.7%). The intended duration of stay in Thailand, mostly they think to stay in Thailand for a lifetime (80.6%).

Accessing to health service of migrants: The migrants mostly do not have health insurance 70.4%and have health insurance 29.6%. The migrants, who have health insurance, pay for health insurance including a migrant health insurance card (47.6%), social security card (38.1%) and others 14.3%. The most migrants accessed health care services in health-promoting hospitals (37.2%), district hospitals (19.5%) and private clinics (12.4%) respectively. The time they traveled from home to the hospital was mostly less than 30 minutes, 91.5% and 43.7% traveling on a motorcycle. When they went to see the doctors at the hospital, most pay the full cost of 66.7% and pay some medical expenses 29.6%. The sickness that went to see the doctors in 6 months ago including cold/stuffy nose (29.5%), crick (27.9%), headache (27.9%) and others (14.7%). In the past 12 months, 81.9% were admitted to hospitals and 28.1% were not admitted. The symptoms they were admitted include colds, malaria, dengue fever and chronic obstructive pulmonary disease. The suggestion to improve services include want to access to medical treatment without having to buy a health insurance card and want to obtain Thai nationality and Thai nationality card.

The attitude of migrants toward the quality of health care services: The migrants had an attitude toward the quality of health care services regarding the quality of services, environment, medicines and medical supplies, health work forces and medical technology. The top 3 attitudes of migrants regarding are 1) confidence in the quality of the public health service according to international standards (4.58) 2) the Surrounding environment of health services that are safe (4.48) and 3) the medicines and medical supplies have quality and standard (4.45). The last 3 attitudes towards services are 1) medical technology is modern and standardized (4.15) 2) the migrants are confident in maintaining confidentiality and respect for patient rights (4.14) and 3) the health work forces are sufficient for providing health services (4.07) show in table 1.

Table 1: Attitude of migrants toward quality of health care service

Attitude of migrants toward quality of health care service	Mean	SD
1. Confidence in the quality of the public health service according to international standards	4.58	0.63
2. The Surrounding environment of health services that are safe	4.48	0.58
3. The Medicines and medical supplies have quality and standard	4.45	0.63
4. A health workforce providing health services for the migrants without discrimination in the context of race, culture, religion, age and gender	4.42	0.60
5. A health workforce listen to problems, understand the feelings of clients and give advice for health care appropriately	4.37	0.67
6. The health service places a good, clean, tidy and well-ventilated environment.	4.37	0.67
7. The migrants are confident in the diagnosis and treatment plan of the doctor.	4.27	0.72
8. A health workforce have expertise and expertise under professional standards.	4.26	0.77
9. The migrants are confident in receiving health services at selected health facilities or near their home.	4.25	0.67
10. A health workforce treat and provide health services to migrants with respect and equity.	4.24	0.75
11. Medical technology is sufficient for service.	4.17	0.77
12. Medical technology is modern and standardized.	4.15	0.73
13. The migrants are confident in maintaining confidentiality and respect for patient rights.	4.14	0.76
14. The health workforces are sufficient for providing health services.	4.07	0.87

Discussion

This paper reveals the barriers of migrant to obtaining access to healthcare in border areas of

Northeast, Thailand. Lack of health insurance is one of the most important barriers in accessing healthcare services among migrant populations as often public health insurance is linked to documentation status [17]. Although the government provides public health rights under the national health insurance system to all people in the Kingdom of Thailand whereas only the migrants who have documents were accepted[18]. Many migrant people do not have access to health services because they do not have enough money to maintain both health checks and treatment when sick. Although the health check service is basic, the migrant population cannot access these services.The lack of health insurance and extremely low incomes make it difficult for migrant to afford health care. The migrant illegal wants to remain anonymous. They do not seek health care community hospitals because of their inability to pay, that can be affected to migrants health[19].

The Thai government should develop a system for a registration system for a migrant in the health system, especially those in the low skill and undocumented migrant are not able to access health services for the benefit of public health primarily without regardless of legal status. It should be linked data to all departments and at every organization level by systematically distributing information through existing channels.[4,17,23-25]

Conclusion

The most immigrants in the research areas were Laotian nationals who moved into Thailand for political asylum. They came without legal permission and intended to live in Thailand for the rest of their lives. Although they knew the information and were interested in having a health insurance card, but considering the annual price, they thought that it is not worth it because most will not have a serious illness. In the case of chronic diseases, they went to receive medical treatment at the Health Promotion Hospital, which does not have any cost for treatment, so they are not interested in purchasing the health insurance card. In the case of those who have a history of illness and being admitted to hospitals, it is necessary to purchase a migrant health insurance card because of the unavoidable illness and the need of purchasing a health insurance card when the illness occurred only.

Legal status has important for applying for a health management system. Obstacles to accessing the health service system due to the lack of legal status which affects various aspects of the migrant population themselves, such as financial barriers, basic welfare and health welfare. The limitations of this paper is to lead to discussion of the problems related to data of migrant to health care access. This study supports the need for further research to develop the database system of migrants, including an update of migrant health policy in Thailand.

Abstract

Ensuring optimum nutrition before and during pregnancy is a critical concern for both mother's and infant's growth. However, the evidence is inconsistent on the effects of maternal diet and weight gain (GWG)during a specific period of pregnancy on low birth weight (LBW) which this study aimed to investigate during late-term pregnancy. This cohort followed 139 pregnant women in Sleman, Indonesia during late-term pregnancy until delivery. Macronutrients intake was assessed using Semi Quantitative Food Frequency Questionnaire (SQ-FFQ). Maternal body weight was measured using a digital scale while pre-pregnancy anthropometry and birth weight were taken from pregnancy books. Statistical analysis was done using simple and multiple Poisson regression test with adjustment model. We found no effect of GWG on LBW. After adjustment for mother's education, parity and intakes of total energy, fat and carbohydrate, inadequate and excessive protein intakes reduced the risk of LBW by 78% (ARR 0.22; 95%CI 0.07-0.74) and 84% (ARR 0.16; 95% CI 0.03-0.99), respectively. In contrast, a6-fold increase in risk of LBW was found among mothers with inadequate fat intake (ARR 5.82; 95% CI: 1.08-31.50).During late-term pregnancy, GWG does not affect LBW while inadequate fat intake is a risk factor of LBW.

Keywords: *Gestational weight gain, maternal nutrition, late-term pregnancy, low birth weight.*

Introduction

Nutritional status of a newborn is greatly affected by the mother's nutritional status before and during pregnancy.[1] Lower pre-pregnancy body mass index (BMI) is associated with lower maternal weight gain (GWG).[2] During pregnancy, inadequate GWG as a result of poor dietary intake has been linked to increased risk of small-for-gestational-age (SGA) neonates and LBW.[3,4] Thus, ensuring a balanced diet before and during pregnancy is a critical concern for both mother's and infant's growth.

There is a strong evidence cohort studies to support the association between maternal nutrition, especially during the later period of pregnancy and birth weight.[3,4] One of the most infamous studies is The Dutch Famine birth cohort study which indicated a significant reduction in birth weight from mothers who were exposed to the famine during their third trimester.[5] However, results from studies regarding the association between specific macronutrient intake such as protein and carbohydrate, GWG and birth weight, are inconsistent [3]. In a study, lower dietary protein intake was associated with smaller size at births[6] while another study indicated

e-mail: toto_sudargo@yahoo.co.id

that no maternal macronutrient intake was correlated with birth weight.[7] In contrast, a study demonstrated negative association between protein intake and GWG.[8] Meanwhile, animal studies demonstrated compromised offspring phenotype from poor intake of protein[9] resulting in reduced birth weight in ratsby 40%.[10,11]

Based on the aforementioned studies, it is known that evidence is inconsistent on the correlation between dietary intake during pregnancy and the pregnancy outcome. Additionally, we focused our observation on anthropometry and macronutrient intakes associated with birth weight in later period of pregnancy. Therefore, the aim of this study was to investigate the effect of macronutrient intakes and anthropometric measurements during the third trimester of pregnancy on birth weight.

Materials and Method

Population and subjects: This was a prospective cohort study conducted across 14 community health centres (PUSKESMAS) in Sleman, Indonesia selected purposively based on prevalence of LBW and stunting at birth. Recruitment process began with listing pregnant women entering the third trimester of pregnancy based on the database at PUSKESMAS. Prospective subjects meeting the inclusion criteria were then enrolled in this cohort: aged 20-40 years and had estimated date of delivery (EDD) in December 2017. Women with multiple birth or premature delivery were excluded from this study. A total of 151 subjects who met the criteria were enrolled in this study. By signing informed consent. Ethical clearance was obtained from the Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada (approval no KE/FK/0986/EC/2017).

Measurements: Data was collected by trained enumerators during home visits in early, mid and late third trimester. Dietary intake was measured through interview using Semi Quantitative Food Frequency Questionnaire (SQ-FFQ). Subjects were asked to inform consumed food items and supplements within the last month including average portion size. Pictures were provided for common food items in household measurements to help quantify food items consumed in gram. Intakes of total energy (TEI) in kcal, carbohydrate, protein and fat in gram were calculated using a Nutrisurvey with Indonesian food database (http://www.nutrisurvey.de).

Body weight was measured by enumerators using digital scale with precision of 0.1 kg. Height and pre-pregnancy body weight was taken from subjects' pregnancy books. Mid-upper arm circumference (MUAC) was measured using a non-elastic measuring tape. GWG was calculated by reducing body weight taken during the third trimester with pre-pregnancy body weight. Birth weight was recorded from verified birth reports. Additionally, demographic data as well as number of pregnancy, type of delivery and food security were also collected by interview.

Data analysis: Statistical analyse were done using Stata SE15 software. Correlations between each independent variable and birth weight were analysed using simple Poisson Regression test. Simultaneously, multiple Poisson Regression analysis was conducted with adjustment form other's formal education, parity and intakes of total energy, protein, fat and carbohydrate. A p-value of <0.05 were considered statistically significant.

Results

In total, 151 pregnant women signed informed consent. However during the cohort, 2 participants had miscarriages, 4 dropped out of the study and 6 moved out of town. Finally, data of 139 subjects was analysed. Baseline characteristics of subjects are presented in Table 1. Mean age of subjects was 29.6 year old. Before pregnancy, subject's mean nutritional status was normal based on BMI (22.6 kg/m^2) and MUAC (27.2 cm). The averages of GWG during the cohort were 12.8 kg. Subject's TEI was 2281.2 kcal in which intake of carbohydrate contributed to the majority of TEI (55.2%). Meanwhile, protein and fat contributed to 13.0% and 34.3% of TEI. Upon delivery, mean birth weight was normal (3101.1 gram).

Table 1. Characteristics of participants (n=139)

Variable	Mean (95% CI)
Age (years)	29.6(28.8–30.4)
Pre-pregnancy BMI (kg/m^2)	22.6(21.9–23.4)
Mid-upper arm circumference (cm)	27.2(26.6–27.8)
Maternal weight gain (kg)	12.8(11.9–13.8)
Total energy intake (TEI) (kcal)	2281.2(2138.2–2424.1)
% Protein to TEI[a]	13.0(12.4–13.6)
% Fat to TEI[a]	34.3(33.3–35.4)
% Carbohydrate to TEI[a]	55.2(54.1–56.3)
Birth weight (g)	3102.1(3030.1–3174.0)

[a]Relative contribution of macronutrient to total energy intake

Table 2 demonstrates the distribution of participants based on sociodemography, anthropometric measurements and nutrition. About 54.7% participants had income above the minimum regional wage standard. About half of participants were either nulliparous (26.6%) or multiparous (25.9%) while 47.5% had previously given birth once. Before pregnancy, BMI of 49.6% of participants was normal while 41.0% was overweight. During the cohort, most participants (89.2%) had normal MUAC. While 41.7% of participants had excessive GWG, 21.6% had insufficient GWG. About half of participants consumed inadequate intake of total energy (45.3%), protein (44.6%) and carbohydrate (48.9%) but excessive intake of fat (50.4%).

Excessive	41	29.5

Our study reported 10LBW cases (Table 3).Simple Poisson regression test was first done to analyse the unadjusted risk relative (RR)of LBWwhen mothers exposed to each independent variables. None of the independent variables affected the risk of LBW, including all anthropometric measurements and micronutrient intakes. Additionally, multiple Poisson regression tests was performed to analyse the adjusted risk relative (ARR) of LBW from mothers with differentGWG. There was consistently no effect of GWG on risk relative of LBW. However, we found that inadequate and excessive intake of protein were protective factors of LBW. Relative to optimum intake of protein, inadequate protein intake reduced the risk of LBW by 78% (ARR 0.22; 95%CI 0.07-0.74) while excessive intake reduced the risk by 84% (ARR 0.16; 95%CI 0.03-0.99). Conversely, there was a greater risk of LBW from mothers with inadequate fat intake compared to adequate intake (ARR 5.82; 95%CI: 1.08-31.50).

Discussion

In our cohort following pregnant mothers throughout their third trimester we found that insufficient GWG during late pregnancy was not a risk factor of LBWin both unadjusted and adjusted models. However, in adjusted model, inadequate and excessive intakes of protein were protective factors of LBW while inadequate fat intake increased the risk of LBW.

The present study was conducted in rural and semi-urban areas of Sleman, Indonesia. Most of our participants were high school graduates and nearly 50% had income below the regional minimum wage standard. LBW occurred in 7.2% of deliveries. This prevalence was lower compared to a body of evidence reporting that pregnant women in rural area are more likely to experience small-for-gestational-age (SGA) and small size at birth[12]due to poverty[13] including a study in Lombok, Indonesia.[14]

GWG has been reported to be independently associated with birth size specifically in third trimester.[15] However, our study found no effect of GWG on birth weight. During the cohort, participants gained adequate GWG (12.8 kg) according to the recommendation for pregnant women with normal pre-pregnancy BMI (11.5-16.0 kg).[16] Compared to previous study conducted in Central Java, a similar location to our study, our participants had higher total GWG by 3.4 kg.[17]

Insufficient foetal nutrition is inclined with undernutrition to the foetus.[18] However, evidence for the effects of dietary composition on birth weight is inconclusive. In our study, when analysed using simple Poisson regression test, neither TEI nor single macronutrient intake affected birth weight. Howeverin the adjusted model of multiple Poisson regression including GWG, mother's formal education, parity, intake of total energy, carbohydrate and fat, inadequate or excessive intake of protein during late-term pregnancy reduced the risk of LBW. This result is in contrast with previous studies reporting adverse birth weight from both low[10,11] and high protein intake.[19] Mean while in terms of fat intake, our study indicated that inadequate fat intake was a risk factor of LBW in the fully adjusted model. This particular result is in agreement with evidence from animal studies reporting that both inadequate and excessive intake of nutrition resulted in reduced birth weight.[20]

The average TEI of our participants during the cohort was 2281 kcal which is slightly higher compared to result from a review of studies conducted in low- and middle-income countries (2055 kcal)[21] including in China (2043.8 kcal) which was also observing pregnant women in third trimester.[22] Although higher, this intake is lower than the guideline recommending pregnant women aged 19-29 years to consume 2250 kcal with an added energy intake of 300 kcal during the third trimester. However, our participants still managed to have an adequate GWG despite not meeting the minimum recommendation.

Our results should be interpreted with regards to several strengths and limitations. Dietary intake was assessed using an FFQ, thus information highly relied on participant's memory. Determination of participant's GWG was calculated from body weight data measured using different instruments. Body weight during cohort was measured directly while pre-pregnancy body weight was taken from a secondary data at local PUSKESMAS. Additionally, although our analysis was adjusted for potential confounders, it is worth noting that there were some other confounders that we weren't able to capture in our study such as meals frequency, family support, pregnancy gap, consumption of anthelmintic and antibiotics.

Conclusion

In our prospective cohort, we found no effect ofGWG during late-term pregnancy on birth weight. Meanwhile, inadequate intake of fat is a risk factor of LBW.

Combined Versus Single Method for Induction of Labor

Wasan Faiz Kareem[1], Henan D. Skheel Aljebory[2], Kawakeb N. Abdulla[3], Hayder A. Fawzi[4], Saba Jassim Alheshimi[5]

[1]Lecturer, Department of Obstetrics and Gynecology, Al-Yarmouk Teaching Hospital, [2]Professor, Department of Obstetrics and Gynecology,College of Medicine, Al-Mustansiriyah University, [3]Lecturer, Iraqi National Cancer Research Center, University of Baghdad, [4]Senior Lecturer, Department of Pharmacy, Al-Rasheed University College, Baghdad, Iraq, [5]Lecturer, Department of Gynecology and Obstetrics, College of Medicine, Misan University, Iraq

Abstract

Objective: Assess the efficacy and safety of combined intracervical Foley catheter and low dose vaginal misoprostol for induction of labor in comparison with the use of misoprostol alone and Foley's catheter alone.

Materials and Method: A prospective interventional open-label study, it includes 120 pregnant women admitted for induction of labor (IO) at a tertiary care center. Women are primigravida, ≥37 gestational weeks with a singleton fetus in cephalic presentation, intact membranes and a Bishop score of <4. The patient divided into three groups (40 patients each); Foley catheter and misoprostol group, only misoprostol group and only Foley catheter group. The primary outcome was the induction-to-delivery interval the secondary outcome variables included rate of vaginal deliveries, uterine hyperstimulation, cesarean section rate, Apgar scores at 1 and 5 min, neonatal intensive care unit admissions and chorioamnionitis

Results: The most common cause of IOL was postdated 43.33%, followed by hypertension 20.83% and Oligohydramnios 20% then gestational DM 12.5 %. The mean induction to the delivery interval was statistically significant shorter in misoprostol – Foley combination 17.48 ± 4.65 hr., in comparison with Foley only 21.84 ± 5.50 hr and only misoprostol 19.62 ± 3.62 hr (p = 0 . 003).Regarding successful induction, the combination had the highest rate of 77.5%, followed by intravaginal misoprostol (72.5%) then Foley catheter only (62.5%). Uterine hyperstimulation, chorioamnionitis and fetal distress were not statistically different among the groups,while the rates of meconium-stained liquor were significantly higher in intravaginal misoprostol 30% and 12.5% in Foley receiving women and 7.5% in the combination p = 0.018.

Conclusion: There is a significant reduction in the induction-to-delivery interval by concurrent use of Foleys' catheter with vaginal misoprostol,rates of meconium-stained liquor was significantly higher in the vaginal misoprostol group.

Keywords: *Misoprostol, Foleycatheter, hypertension, induction of labor, combined therapy.*

Introduction

Induction of labor (IOL) defines as the process by which labor is started prior to its spontaneous onset by artificial stimulation of uterine contractions and/or progressive cervical effacement and dilatation, leading to active labor and birth[1]. Augmentation refers to the enhancement of spontaneous contractions that are

considered inadequate because of failed cervical dilation and fetal descent[2]. The term IOL generally refers to a procedure performed in the third trimester but may be applied at gestations greater than the legal definition of fetal viability,when the fetal survival is an anticipated outcome, any procedure performed prior to this gestation may be classified as a termination of pregnancy [3].

The induction of labor became an important part of the modern gynecological procedure which occurs in 15% of all pregnancies. The status of the cervix constitutes an important factor that affects the success of labor and it had been established that its status predicts the inducibility of labor [3]. "The most effective method for inducing labor has not been established in the medical literature "This is likely due, in part, to the lack of head-to-head studies comparing multiple induction agents [4]. The current study aimed to assess the efficacy and safety of combined intracervical Foley catheter and low dose vaginal misoprostol for induction of labor in comparison with the use of misoprostol alone and Foley's catheter alone.

Method

Study Setting: This prospective non-blinded open-label trial was conducted in Obstetrics and Gynecology Department at Al- Yarmouk teaching hospital in the period from March 2017 to December 2017, including 120 pregnant women admitted for induction of labor at a tertiary care center. Written informed consent was obtained from participants in the trial prior to enrolment. They were primigravida with gestational age ≥37 weeks single viable fetus, cephalic presentation with intact membranes, absence of labor and a modified Bishop score of <4 done by same examiner women with multiple pregnancy, non-reassuring fetal heart rate trace, ruptured membranes, active genital infection, previous uterine surgery (including cesarean section), intrauterine fetal death, low-lying placenta and estimated fetal weight >4000 g were excluded.

Data Collected: Demographic details, prior medical and obstetric history, baseline non-stress test (NST), the course of labor and indication for induction were documented.

Study Design: The patient divided randomly into three interventional groups 40 patients in each group, patients in Saturday and Tuesday received Foley catheter and misoprostol, in Sunday and Wednesday received misoprostol only and in Monday and Thursday received Foley catheter only

The first group received a Foley catheter and misoprostol (combined method) for the induction of labor. A 16-Fr Foley catheter was inserted into the endocervical canal under direct visualization during a sterile bivalve speculum examination 30ml of sterile water was injected into the balloon once the catheter passed the internal os. Traction was applied by taping the end of the catheter to the medial side of the knee or thigh. After securing the catheter in place, a 25-µg moistened misoprostol tablet (Vagiprost) was inserted into the posterior vaginal fornix under aseptic precautions. The Foley catheter was retained in situ till spontaneous expulsion or for a maximum duration of 12 h.

The cervix was assessed every 4 h by Bishop score and a 25-µg misoprostol tablet was inserted 4-hourly, up to a maximum of eight doses if the score was ≤6. The Foley catheter was removed if any of the following occurred: non-reassuring fetal heart rate (FHR) and spontaneous membrane rupture.

In the second group patient received only misoprostol, 25-µg misoprostol tablet (moistened with normal saline) was inserted into the posterior vaginal fornix The cervix was assessed every 4 hours by Bishop score and a 25-µg misoprostol tablet was inserted 4-hourly, up to a maximum of eight doses. The patient in the third group received only Foley catheter without misoprostol. The Foley catheter was retained in situ till spontaneous expulsion or for a maximum duration of 12 hours.

The fetal condition and assessment of uterine contractions were monitored in both groups by CTG half an hour prior to each scheduled dose of misoprostol and continues fetal monitoring during active labor. The final Bishop score was noted when the patient was taken into the labor ward. Active management of labor was done with amniotomy followed by low-dose oxytocin augmentation.

Oxytocin (Syntocinon) infusion was started at the rate of 1 mU/min and escalated every 30 min until regular uterine contractions were achieved or up to a maximum of 20 mU/min. The progressing of labor monitored by partogram. If the patient failed to achieve efficient uterine contraction or changes in Bishop's score, the subsequent management of those women was individualized.

Outcomes of the study: The primary outcome was the induction-to-delivery interval. The secondary outcomes of interest included rate of vaginal deliveries, uterine hyperstimulation incidence of cesarean section, neonatal outcomes (birth weight, Apgar scores at 1 and 5 min, neonatal intensive care (NICU) admissions) and chorioamnionitis.

Statistical Analysis: Discrete variables presented using there number and percentage used to present the data, chi-square test used to analyze the discrete variable, one way ANOVA used to analyze the differences between more than two groups (if they follow a normal distribution with no significant outlier). SPSS 20, Graph Pad Prism 8.1 software package used to make the statistical analysis, p-value considered when appropriate to be significant if less than 0.05

Results

There was no significant difference among the different groups of the study in their age, BMI, Bishop Score and gestational age at delivery. There was no significant difference in the outcome of induction of labor; however, the combination had the highest success rate (77.5%), then low dose vaginal misoprostol (72.5%) and least Foley with (62.5%). Both combination and vaginal misoprostol had a significantly higher rate of delivery within 24 hours (67.5% and 62.5%) compared to Foley only (32.5%) as illustrated in table 1.

Table 1: Assessment of maternal clinical data

Variables	Foley Only	Vaginal Misoprostol	Combination	P value
Number	40	40	40	-
Maternal age (y), mean ± SD	21.08 ± 4.54	20.93 ± 4.21	21.68 ± 4.42	0.722
BMI (kg/m^2), mean ± SD	23.75 ± 3.40	23.46 ± 2.94	24.35 ± 3.74	0.489
Bishop score, mean ± SD	1.78 ± 0.77	1.80 ± 0.82	1.68 ± 0.76	0.753
1	17 (42.5%)	18 (45.0%)	20 (50.0%)	-
2	15 (37.5%)	12 (30.0%)	13 (32.5%)	
3	8 (20.0%)	10 (25.0%)	7 (17.5%)	
Gestational age (weeks), mean ± SD	39.34 ± 1.64	39.54 ± 1.55	38.53 ± 5.85	0.423
Induction of labor				
DM	4 (10.0%)	5 (12.5%)	6 (15.0%)	0.850
Hypertension	9 (22.5%)	8 (20.0%)	5 (12.5%)	
IUGR	4 (10.0%)	1 (2.5%)	2 (5.0%)	
Oligohydramnios	8 (20.0%)	8 (20.0%)	8 (20.0%)	
Postdates	15 (37.5%)	18 (45.0%)	19 (47.5%)	
Outcome of induction				
Successful	25 (62.5%)	29 (72.5%)	31 (77.5%)	0.323
Not successful	15 (37.5%)	11 (27.5%)	9 (22.5%)	
Delivery within 24 hours				
>24 hours	27 (67.5%)	15 (37.5%)	13 (32.5%)	0.003
≤24 hours	13 (32.5%)	25 (62.5%)	27 (67.5%)	
BMI: Body mass index, SD: standard deviation				

Women using combination therapy had the shortest time to achieve delivery (17.48 ± 4.65), followed by low dose vaginal misoprostol (19.62 ± 3.62) than women using Foley having the longest time (21.84 ± 5.50) as illustrated in figure 1.

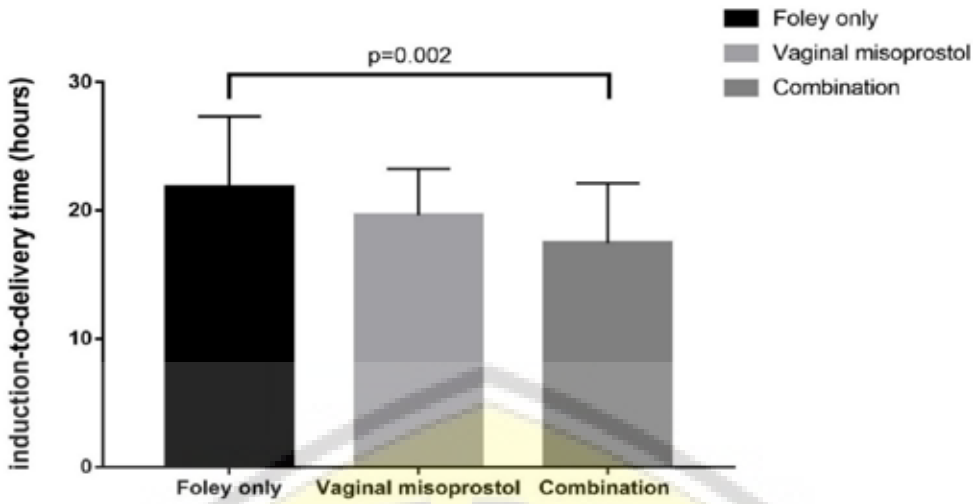

Figure 1: Histogram of mean time to induction for different groups

Vaginal misoprostol had significantly the highest Meconium stained liquor rate (30%) compared to both Foley only (12.5%) and combination (7.5%) p = 0.018. about 30% of Vaginal misoprostol and combination require oxytocin while 40% of Foley receiving women and there was no significant difference between the groups, C/S rate was lowest in combination followed by Vaginal misoprostol and Foley and there was no significant difference between them, Chorioamnionitis was lowest in Vaginal misoprostol there was no significant difference between them as illustrated in table 2.

Table 2: Labor details and complications

Variables	Foley only	Vaginal misoprostol	Combination	P-value
Number	40	40	40	-
Require oxytocin	16 (40.0%)	12 (30.0%)	8 (20.0%)	0.149
Uterine hyperstimulation	3 (7.5%)	5 (12.5%)	3 (7.5%)	0.670
C/S	15 (37.5%)	11 (27.5%)	9 (22.5%)	0.323
Meconium stained liquor	5 (12.5%)	12 (30.0%)	3 (7.5%)	0.018
Chorioamnionitis	2 (5.0%)	1 (2.5%)	4 (10.0%)	0.346
Fetal distress	3 (7.5%)	6 (15.0%)	2 (5.0%)	0.272
Chi-square test				

There was no significant difference in APGAR score after 1 minute and after 5 minutes, fetal weight and neonatal care unit admission between the groups as illustrated in table 3.

Table 3: Neonatal outcomes

Variables	Foley Only	Vaginal Misoprostol	Combination	P value
Number	40	40	40	-
APGAR 1 min	6.90 ± 1.11	7.08 ± 1.00	7.05 ± 0.88	0.691
≥7	35 (62.5%)	31 (77.5%)	30 (75.0%)	
<7	15 (37.5%)	9 (22.5%)	10 (25.0%)	
APGAR 5 min	8.85 ± 1.05	8.95 ± 0.99	9.13 ± 0.76	0.406
≥7	39 (97.5%)	40 (100.0%)	40 (100.0%)	
<7	1 (2.5%)	0 (0.0%)	0 (0.0%)	
Fetal weight (kg)	3.04 ± 0.40	3.13 ± 0.30	3.16 ± 0.25	0.228
Neonatal care admission	4 (10.0%)	6 (15.0%)	2 (5.0%)	0.329
One-way ANOVA				

Discussion

In the current study the most common indication for labor induction was postdate, followed by hypertension and Oligohydramnios (both equal proportion) then gestational diabetes mellitus, our findings were in agreement with recent guideline of Society of Obstetricians and Gynaecologists of Canada revealing similar pattern of cause of labor induction[5], Al-Ibraheemi et alreported that postdate, Oligohydramnios and hypertension were the most common indications for labor induction[6], while Lanka et al reported in addition to postdate, Oligohydramnios, hypertension gestational diabetes mellitus as common indications[7].

In the current study misoprostol – Foley combination offeredshorter time of induction of labor in comparison with misoprostol only and Foley only (17.48 ± 4.65 hours versus 19.62 ± 3.62 hours) and (17.48 ± 4.65 versus 21.84 ± 5.50 hours) respectively, it was statistically significant. Regarding successful induction, the combination method had the highest rate of 77 . 5 % , followed by intravaginal misoprostol (72.5%) than Foley catheter only with (62.5%) success ; however no significant difference was found, also there was no significant difference in the rates of cesarean section 22.5%, 27.5%, 37.5% respectively between the study groups.

Chunget al which includes 146 patients, 49 patient was assigned to misoprostol, 54 were assigned to Foley only and 43 were assigned to combined therapy and reported no statistical difference in the rate of vaginal delivery (57 – 63%), induction to delivery time with combination having the faster time 16.6 hours followed by misoprostol only 17.5 hours and Foley only 19.5 hours[8], Kashanian et al which include 300 patients divided into three groups (misoprostol only Foley only and Foley with misoprostol only) 100 patients for each group and reported a controversial findings of intravaginal misoprostol being the shortest compared to combination and Foley only in which they reported 10.5, 12.3 and 11.7 hours in the misoprostol, Foley and combination and the difference was statistically significant among the groups, while similar to our findings and others the rates of vaginal delivery was (60 – 65%) with no statistical difference between the groups[6].

Lanka et alwhich includes 126 patient divided into two groups (misoprostol only and misoprostol with Foley) 63 patients for each group andreported no significant in the time from labor to induction between combination and misoprostol only 26.5 vs. 27.6 hours and the rate of vaginal delivery (65.1% vs. 65.1%)[7]. A combination of method for induction of labor is more effective than a single method, according to results from the randomized Foley or Misoprostol for the Management of Induction (FOR MOMI) trial by Levine et al[9], this study included 492 patients divided into four groups (misoprostol only, Foley only, Foley with misoprostol and Foley with oxytocin), 123 patients, for each group anddesign their study in attention to treat principle and they reported that women using either Foley or misoprostol only are 50% less likely to deliver before women receiving combination of both (HR = 0.52, HR = 0.53, respectively), median time to delivery 13.1, 17.6 and 17.7 hours for combination, misoprostol and Foley respectively which is in agreement with our findings and no significant difference in the rate of vaginal delivery among the groups.Al-Ibraheemi et alwhich includes 200 patients divided into two groups (misoprostol only and misoprostol with Foley) 100 patients for each group and reported similar findings to the current study in which combination had a significantly shorter time to delivery 16.0 hours vs. 18.9 hours in the misoprostol group, additionally no significant difference in the mode of delivery was found[10]. Possible explanation of this discrepancy in the time from induction to delivery is due to difference in the study design in which the two recent studies[9, 10], which published in 2016 and 2018 and had both design with sufficient power of detection (i.e. 80% and type I error of 5%) and intention to treat principle design were in agreement with our finding, while older studies[6-8], were in disagreement with our findings, while in term of rates of deliveries all these studies were in agreement with the current study.

Conclusion

Our study reported a statistically significant reduction in the induction-to-delivery interval by concurrent use of Foley's catheter with vaginal misoprostol and the rate of meconium-stained liquor was significantly higher in vaginal misoprostol

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study and the study and all its procedures were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by the Iraqi Board of Medical Specializations.

Oral Health Knowledge among Public School Students in Pondok Labu Sub District South Jakarta

R. Rikawarastuti[1], N.N. Kasihani[1]

[1]Department of Dental Nurse, Jakarta 1 Health Polytechnic Ministry of Health, Jakarta, Indonesia

Abstract

Oral health of children are strongly influenced by level of knowledge. The purpose of this research is to study the level of oral health knowledge among public school students 01 in Pondok Labu Sub District, South Jakarta. This research method was cross sectional study. The research subject is 76 students of fifth grade. Measured variables are class, age, sex, number of siblings and mother's employment status of respondents. Data were collected using a questionnaire on May 2017. Data is analyzed by using chi square and logistic regression. Results show that the research population consists of 76 respondents between 10-12 years old. The knowledge of oral health respondents 75 % is good. Analysis multivariate showed that there is significant relation between level of knowledge and grade of class (p value 0.03). However, there are no significant relation between level of knowledge and age, sex, the number of siblings and mother's employment status of respondents. Knowledge of respondents is less good on advantage of toothpaste containing flour, symptoms of toothache and types of snack which damage teeth. We recommend giving education program to improve oral health knowledge of students at school age groups.

Keywords: *Knowledge, oral health, school student.*

Introduction

Oral health is an important issue in public health with a major impact on the general health status of individuals[1,2]. Oral health is one of the health aspects that need to be focus, including in children[3,4]. Child's oral health is part of physical health can affect child development. The most common oral health problems are dental caries, periodontal disease and dental trauma. Oral health promotion in schools recommended by the World Health Organization (WHO) to improve the knowledge, attitudes and behaviors related to oral health as well as doing prevention and control of dental diseases in school age children[2].

Oral health education provides knowledge of proper oral hygiene, to improve attitude of oral health and apply that knowledge and attitudes into practice[5]. Knowledge is derived from information which is accepted to be translated into action which in turn becomes a habit. A good knowledge about oral health is important for oral health behavior[6].

Research on level of oral health knowledge at primary school students in Indonesia is quite often conducted to write thesis. However, they are published on limited number. Those have shown inconsistent results in level of students' knowledge, due to differences in socio demographic characteristics of population. Elementary school students in Indonesia were varied into public primary schools, national private schools, Islamic private schools, Catholic private schools, etc. A public school is open to children from different socioeconomic classes. Thus, the purpose of this study was to obtain an overview of oral health knowledge among student of public-school in Pondok Labu Sub District, South Jakarta.

Method

The study design used is cross sectional studies. Research was conducted in March to June 2017 in

public school number 01 in Pondok Labu Sub District, South Jakarta. Population was all students in public school number 01 in Pondok Labu Sub District, South Jakarta. Sample is determined by purposive sampling which taken from fifth class as many as 80 students. Response rate is 95% therefore the number of samples is 76 respondents. Public school number 01 is school which has UKGS (dental health unit of school) under jurisdiction of Pondok Labu's Community Health Centre.

Instrument used in study is a questionnaire arranged by 10 questions to measure the level of oral health knowledge. Questionnaire has been tested by validity and reliability test in 50 students and showed that there were 10 items are valid questions to be used (Cronbach alpha = 0.729) and reliable (r table - 0273). Variables that measured are characteristics of respondents such class, age, gender, a few siblings and maternal employment status of the respondents. Data is analysed using chi square test and logistic regression.

Results and Discussions

Public school number 01 in Pondok Labu Sub District, South Jakarta is located next to Pondok Labu Community Health Centre. This school has done maintenance activity for UKGS through some counseling but never assed level of success of those activities.

These results indicate that the sample consisted of 76 students aged 10-12 years. Students who responded to the fifth-class students are divided into two classes: class VA and VB. Distribution of respondents by sex is almost evenly between men and women. There are 59.2% of the respondents came from planed family which at most two number of child and has a mother who worked as much as 60.5%. Characteristics of students can be seen in Table 1.

This study aimed to describe the level of oral health knowledge of students which is measured using a questionnaire. Results in Table 2 shows that there are still some items that questions cannot be answered correctly, especially on the benefits of fluorine-containing toothpaste, tooth pain symptoms and types of snacks that can damage teeth.

Table 3 shows that the level of knowledge of good oral health majority of respondents (75%) and the rest are not good. The level of knowledge can be influenced by several factors such as the division of class, age, gender, a number of siblings of students and employment status of the mother. Table 4 shows the relationship between the characteristics of respondents with the level of oral health knowledge. It shows that there are two characteristics that are likely to significantly affect the level of the student's knowledge of class divisions and gender ($p < 0.25$).

Table 1. Respondents Characteristics

Variable		Total	
		n	%
Class	5A	40	52.6
	5B	36	47.4
Age	≤ 11 yo	68	89.5
	> 11 yo	8	10.5
Sex	Female	40	47.4
	Male	36	52.6
Number of children	≤ 2	45	59.2
	>2	31	40.8
Maternal employment status	Employed	30	39.5
	Unemployed	46	60.5

Table 2. Answers for each question.

Question	Answer (%)	
	True	False
Dental health understanding	90.8	6.7
How to clean plaque	98.7	1.3
Healthy habit for dental health	89.5	10.5
Right time for brushing	94.7	5.3
Kind of healthy food for dental health	82.9	17.1
Snacks which can damage teeth	81.6	18.4
Part of teeth surface that should be brushed	92.1	7.9
Flour benefit	50	50
Cavity symptom	72.4	27.6
Purpose of dental examination	84.2	15.8

Table 3. Level of Knowledge

Knowledge	Total	
	n	%
Less	19	25
Good	57	75

Table 4. Level of Knowledge toward Characteristics

Variable	Level of Knowledge				OR (95% CI)	P value
	Good		Less			
	N	%	n	%		
Class						
5A	26	65	14	35		
5B	31	86.1	5	13.9	3.34 (1.06 – 10.51)	0.03*
Age						
≤11 yo	51	75	17	25	1 (0.18 – 5.43)	0.60
>11 yo	6	75	2	25		
Sex						
Female	29	80.6	7	19.4	0.56 (0.19 – 1.64)	0.20*
Male	28	70	12	30		
Number of siblings						
≤ 2	33	73.3	12	26.7	1.25 (0.43 – 3.64)	0.45
>2	24	77.4	7	22.6		
Maternal employment status						
Employed	35	76.1	11	23.9	1.05 (0.51 – 2.15)	0.50
Unemployed	22	73.3	8	26.7		

Table 5. Final Modelling of Multivariate for Significant Variables

Variable	B	SE	Wald	P Value	OR	CI 95%	
						Lower	Upper
Class	-1.206	.585	4.247	.039	.300	.095	.943

The final analysis of multivariate as shown in Table 5 shows a significant correlation between the class division with the level of knowledge (p value = 0:03) but not significantly associated with age, gender, a few siblings and maternal employment status of students. Class divisions are extrinsic factors of student characteristics that occur due to interference by other parties therefore some class membered by smart kids. Whereas, the intrinsic factor of student character has no significance.

The results of this study are arguing study in Jeddah Saudi Arabia in 2013 which reveal that gender affects the level of knowledge of elementary school children. Girls are more aware of the gums (P 6: 0001); the effect of oral health general health (P = 0.004); the importance of dental examination (P 6001) and more aware of the colour of the teeth (P = 0.05), than men[6]. However, when comparing the results of this study with research conducted on students International Branch of Shiraz University of Medical Sciences with a more mature age, results did not reveal any significant relationship between oral health knowledge and gender (P> 0.05) [1].

According to research in India[2] oral health education can change the behavior of students. Therefore, primary public-school number 01 needs to be educated for increasing the knowledge and behavior of students in oral health. Education would be more effective to use interactive learning media. It proved to Aborigines in 2011 found an increased knowledge of dental care after educational intervention[1].

Conclusion

The level of knowledge in oral health at student of primary public school is good (75%). There is a significant relationship between the class divisions and level of oral health knowledge. We suggest doing oral health education continuously to improve and maintain the resistance of students' knowledge.

The Development of the Thesis-Writing Perfectionism Inventory

Rahman[1], Punaji Setyosari[2], Adi Atmoko[2], Nur Hidayah[2]

[1]Student of Doctoral Program of Universitas Negeri Malang, Indonesia,
[2]Faculty of Education, Universitas Negeri Malang, Indonesia

Abstract

Previous studies proved that perfectionism is one of the factors causing procrastination in thesis writing. Unfortunately, no inventory that specifically measures perfectionism in the context of thesis writing had been developed. Therefore, this study aimed to develop an inventory of thesis-writing perfectionism that meets several psychometric requirements. The inventory was constructed through four steps: (1) specifying the construct of perfectionism; (2) constructing the measurement model; (3) performing confirmatory factor analysis; and (4) testing the validity of the measurement model. 200 subjects were involved in the study. The validity and reliability of the inventory were examined using exploratory and confirmatory factor analysis and Cronbach's alpha. These steps successfully validated 10 of 20 initially constructed items.

Keywords: *Perfectionism, procrastination, thesis writing, assessment, research and development.*

Introduction

Procrastination in academic tasks can be found widely in many education settings. A study reported 40–50% of students to be in the chronic level of procrastination [(1)]. In detail, it was also reported that 87% of students have delayed in preparing and submitting their assignments, 68% in presenting assignments and 62% in preparing themselves for the exam[(2)]. Moreover, other studies conducted in Indonesia also affirm similar results. A study conducted in Universitas Surabaya found that 30.9% of 316 subjects conducted academic procrastination at high to very high level [(3)]. A similar research conducted in Universitas Pendidikan Indonesia also discovered that 44.08% of students were always procrastinating, 53.55% occasionally procrastinating and only 2.07% never procrastinating[(4)].

One of the most often postponed academic assignments by undergraduate students is thesis writing. According to data obtained from the Office of Information Center of Universitas Negeri Malang in January 2018, there are 3.687 (12.45%) of 29.613 bachelor's degree students were delaying their graduation. 96% of them graduated late due to their procrastinated thesis writing. Moreover, it was also reported in a study conducted in Institut Agama Islam Negeri Antasari that thesis writing was one of the factors delaying the graduation of the students [(5)]. The similar result was also observed at the Faculty of Psychology, Universitas Surabaya[(6)].

Perfectionism is one of the predictors of procrastination. Several studies showed that it has a direct effect on procrastination[(7,8)]. Other studies also proved that perfectionism is a good predictor of academic procrastination through self-efficacy [(9)], self-regulation [(10)] and motivation [(11)]. Based on the studies, it can be concluded that perfectionism is one of the variables that must be considered in the procrastination intervention.

Unfortunately, there are no assessment tools that can measure the perfectionism in the context of thesis writing specifically. The existing perfectionism scales only measure the perfectionism in the general context[(12–15)]. The scales are widely used in various research and counseling/psychotherapy services and have adequate psychometric eligibility in their own

Diniy Hidayatur Rahman
e-mail: diniy.hidayatur.fip@um.ac.id

respective contexts. However, because of the general context they use, measuring perfectionism in the thesis writing context using these instruments is not really appropriate.

Based on the discussed background, this study aimed to develop a scale called the *Thesis-Writing Perfectionism Inventory* (TW-PI). The inventory was developed based on the construct of self-oriented perfectionism proposed by Hewitt & Flett [12,16] and two main indicators of perfectionism proposed by Rice, et al.[17] *High standard* refers to an individual's tendency to adhere to standards that are excessively high about his/her performance, while *discrepancy* refers to the belief that he/she will find the standards difficult to achieve. In order to measure the perfectionism in thesis writing context specifically, the items of the TW-PI was constructed in the context of thesis writing.

Material and Method

The study applied research and development design. To develop the scale, the study followed the steps of: (1) defining the construct of perfectionism; (2) developing the construct measurement model; (3) conducting confirmatory factor analysis (CFA) to empirically evaluate whether the developed construct confirms the theory or not; and (4) evaluating the validity of the measurement model [18].

200 undergraduate students of Universitas Negeri Malang (UM) writing their thesis participated in the study. The number was obtained by multistage cluster sampling. Firstly, the researcher identified the number of students writing the thesis in eight faculties at UM. Based on subjects grouping according to their faculties, 25% of departments from each faculty were randomly chosen as representatives of the faculties. Finally, the researcher randomly selected 200 students writing the thesis in the representative departments to determine the final sample. Selected subjects were then contacted by telephone or e-mail to fill out the online or offline prototype of the scale.

Table 1. The Initial Blueprint of the TW-PI

Variable	Indicators	Items
Thesis-Writing Perfectionism	High Standard	1. I want to write an extraordinary thesis
		2. Writing an ordinary thesis makes me uncomfortable
		3. I will try to write a thesis as perfect as possible
		4. I will not show the thesis to my supervisor before it is well written
		5. I feel disappointed in myself if my supervisor finds weaknesses in my thesis
		11. I don't care about the quality of the thesis, my goal is to get it done immediately
		12. For me, the thesis does not need to be perfect
		13. Reaching the minimum standard is enough for my thesis
		14. The ideal thesis will only complicate myself
		15. It is fine if the quality of my thesis is mediocre
	Discrepancy	6. I find it difficult to write a thesis with a standard that I set
		7. The thesis I wrote is not enough to reach the standard I set
		8. With the remaining time, it seems difficult to write a thesis according to my standards
		9. Even though I have come this far, I feel that my thesis has not reached the standard I have dreamed of
		10. It turned to be very difficult to carry out the thesis writing plan I made
		16. I think I have reached my target in writing a thesis
		17. It's not too difficult to reach the standard I want in writing a thesis
		18. I am satisfied with my thesis
		19. I am happy with my achievement in thesis writing
		20. My thesis is currently sufficient to represent the standard I want

Favorable Items: 1-10; Unfavorable Items: 11-20

The construct validity of the scale was evaluated using *the exploratory factor analysis* (EFA) by checking the *Kaiser-Meyer-Olkin Measure of Sampling Adequacy* (KMO-MSA) value. If the KMO-MSA value is ≥ 0.5 with $p \leq 0{,}05$, the analysis can be continued. In addition, if the value of the MSA for a particular item is ≥ 0.5, it can go for further analysis. The next step is extracting the eligible items with the *varimax method*. The item that has a loading of ≥ 0.5 for an indicator will be regarded as a good item. However, the item will be regarded as not meeting the theoretical assumptions if it is extracted into an incorrect indicator. Thus, the item must be discarded even though it has a loading of ≥ 0.5 statistically. Furthermore, indicators that have a loading of ≥ 0.5 for a developed construct will be determined as an eligible indicator. Valid items and indicators based on the EFA will then be tested for their reliability with the *Cronbach's alpha*. The coefficient of *Cronbach's alpha* used in the study is > 0.7. The next is performing CFA with a second-order technique. The analysis will test the unidimensionality of the TW-PI. In this study, it will be determined by *The Root Mean Square Error of Approximation* (RMSEA) of ≥ 0.08. The validity of an item for an indicator and an indicator for a construct will be determined by the *Lambda* of ≥ 0.4.

Findings:

The Initial Blueprint of the TW-PI: Based on the review of the main indicators of perfectionism and the context of thesis writing, the researcher constructed 20 items extracted from two indicators: *high standards* and *discrepancy*. Detailed descriptions of indicators and items are displayed in table 1. Four Likert answer choices were provided for each of these items, ranging from disagree to strongly agree.

The Result of EFA, Cronbach's Alpha and CFA: The EFA of 20 items of the TW-PI showed that the ten of them had a loading factor of ≥0.5, while the other ten (items 1, 2, 3, 4, 5, 6, 7, 8, 9 and 10) had a loading factor of <0.5. Therefore, the ten were categorized as valid items, while the rests were invalid. Likewise, both TW-PI indicators had a loading factor of 0.758 on the Thesis-Writing Perfectionism variable. The EFA also grouped the ten valid items into two appropriate indicators. Items 11, 12, 13, 14 and 15 were grouped in *high standard*, while items 16, 17, 18, 19 and 20 in *discrepancy*. Cronbach's alpha analysis was then performed on the ten to evaluate their reliability. The result showed that the items were completely reliable since they have the *Cronbach's alpha* coefficient of >0.7. The detail results are summarized in table 2.

The items were then tested using CFA to evaluate the unidimensionality of the measurement model and the validity of each item. The details of the results are shown in table 2. It can be seen in table 2 that the RMSEA was 0.073 which means that the measurement model was good. The value of *Chi-Square* was 201.41 with a probability of 0.05303 which means that the measurement model had obtained adequate empirical support. Furthermore, *The Lambda* of all items and indicators was >0.4, which means that the items and indicators were valid.

Table 2. The Result of EFA, Cronbach Alpha Analysis and CFA

Indicators	EFA		Cronbach's Alpha		CFA			
	Item Grouping	Loading Factor	Cronbach's Alpha	Corrected Item-Total Correlation	Lambda	RMSEA	Chi-Square	P
High Standard (Loading Factor = 0,758; Lambda = 0,72)	11	0,802	0,857	0,639	0,62	0,073	201,41	0,05303
	12	0,921		0,726	0,75			
	13	0,878		0,473	0,52			
	14	0,811		0,396	0,54			
	15	0,897		0,711	0,62			
Discrepancy (Loading Factor = 0,758; Lambda = 0,59)	16	0,821		0,628	0,55			
	17	0,865		0,512	0,51			
	18	0,876		0,376	0,60			
	19	0,915		0,572	0,51			
	20	0,923		0,587	0,69

Discussion

Perfectionism is individual's tendency to set high standards excessively for him/herself so that it makes him/her hesitate to act immediately [19]. He/she demands him/herself to always be competent, great and excel in all fields he/she considered important[20]. This definition refers to the unidimensional construct of perfectionism. However, after 1990s, the concept of perfectionism shifted from unidimensional to multidimensional[21]. One of the most popular concepts of multidimensional perfectionism is that put forward by Hewitt & Flett [12,16] and Frost, et al.[13]

Hewitt & Flett said that perfectionism has three dimensions: (1) *self-oriented perfectionism*; (2) *other-oriented perfectionism*; and (3) *socially prescribed perfectionism*[12,16]. In anothe side, Frost et al. also stated that it has six dimensions: (1) *concern over mistakes*; (2) *doubts about action*; (3) *personal standards*; (4) *parental expectations*; (5) *parental criticism*; and (6) *organization* [13]. Compared to the dimensions proposed by Hewitt & Flett which contain the classification of the actors of perfectionism, the dimensions by Frost, et al. seems to explain the indicators of perfectionism. However, Egan, et al.[22] criticized these dimensions because they do not represent the core dimensions of perfectionism. They categorized *parental expectation* and *parental criticism* as causes of perfectionism and not the perfectionism itself. *Concern over mistakes* and *doubts about action* were also criticized because both were considered to be a same construct so they must be put together. Furthermore, Frost et al. also doubted *organization* as a dimension of perfectionism[13]. In conclusion, the remaining two dimensions are considered to be the core dimensions of perfectionism, namely: (1) the combination of *concern over mistakes* and *doubts about action*; and (2) *personal standards*.

The results of the study reinforce the criticism of Egan, et al. that the six indicators of perfectionism proposed by Frost et al. are not entirely correct. Confirming the criticism, the results of this study show that *high standards* (*personal standards*) and *discrepancy* (the combination of *concern over mistakes* and *doubts about action*) have a high loading factor for the thesis-writing perfectionism variable. Therefore, these two indicators are appropriate to represent the thesis perfectionism construct. This is also proven by items grouping on the two appropriate indicators which means that the items are extracted correctly from the two. These results confirms the previous research by Rice, at al. that found *high standards* and *discrepancy* as the main dimensions of perfectionism.[17]

Psychometrically, the TW-PI has conditions that must be owned by a scale. The results of EFA, CFA and *Cronbach's alpha* showed that the scale is valid and reliable. When compared to similar instruments, this scale has the advantage of a small number of items. That way, the scale can serve simple assessment that is increasingly needed lately. As known, counseling services which lately tend to be brief require assessment instruments that are also brief and simple. However, because the TW-PI is in its early stages of development, one of its shortcomings is that it has not been proven to correlate with a similar scale. Therefore, the convergent validity of this scale is still unknown. The task of the next research is to examine the correlation of the TW-PI with other similar scales.

Conclusion

The development and validation process of the TW-PI had selected ten valid and reliable items and eliminated the other ten that do not meet the psychometric requirements. These items are only intended to measure the level of perfectionism in the context of thesis writing. Therefore, the score resulted is the total score of perfectionism in thesis writing. The higher the score, the higher the perfectionism tendency of the subject. On the contrary, the lower the score the lower the perfectionism tendency. Compared to similar instruments, the TW-PI has several advantages: (1) it only contains 10 items so that it is very efficient to use; and (2) it is very appropriate to be used in counseling setting. One of the disadvantages of the TW-PI is the number and homogeneity of the samples used in the development process. This sample number limits the use of the TW-PI only to the population of subjects involved.

[2]Environmental Health Department, Faculty of Public Health, Hasanuddin University, Makassar

Abstract

Introduction: The increasing number of incidents and prevalence has made Sexually Transmitted Infections (STIs) a particular highlight and problem for the Indonesian government. STI transmission is generally due to dangerous sexual behavior. According to the WHO, there are at least 1 million cases of STIs found every day. In 2017, there were 276 cases of syphilis and 383,290 cases of HIV-AIDS in Central Sulawesi, as well as Undata General Hospital in Palu reported 102 cases of HIV. Objective :This study aims to determine the risk factors in the form of age, gender and marital status of the incidence of sexually transmitted infections (STIs) in patients of Internal Medicine and Dermatology & Venereology Polyclinic in 2018. Research method :This research study is quantitative with a case-control approach. The sample in the study was 152 with a ratio of 1:3 consisting of 38 case samples and 114 control samples; taken using the simple random sampling method. The data were obtained from medical records of patients in the Undata General Hospital in 2018.

Results: The study produced the following data: <25 years old (OR = 3.165; 95% CI = 1.482-6,761), female sex (OR = 1.873; 95% CI = 0.887-3,959) and marital status (OR = 3.175; 95% CI = 1,471-6,857). Conclusion :Age, sex and marital status were the risk factors caused sexually transmitted infections (STIs) in patients of Internal Medicine and Dermatology & Venereology Polyclinic in 2018. Health workers are expected to be able to increase counseling related to STI issues as a preventative measure so that the number of cases can be reduced.

Keywords: *Sexually Transmitted Infection, Age, Gender, Marital Status.*

Introduction

Sexually Transmitted Infections (STIs) are one of the most critical public health problems in developed and developing countries. The asymptomatic nature of some STIs and difficult diagnostic procedures show that many cases of STIs remain difficult to detect[1]. STIs are also associated with symptoms of serious illnesses such as pelvic inflammation, infertility, ectopic pregnancy, cervical cancer, neonatal death, prematurity and congenital deformity. In addition, STIs are also often considered to facilitate the transmission of the HIV and Hepatitis B (HBV) virus[2,3].

Sexually transmitted infections have a prominent impact, for example, about one third of pregnant women infected with Syphilis give birth to adverse outcomes including stillbirth and infection of Human Papillomavirus (HPV). This causes around 266,000 deaths from cervical cancer per year and some STI bacteria lead to pelvic inflammatory disease, female infertility, premature birth and low birth weight babies[4].

Every year, there are about 131 million chlamydial infections, 78 million gonorrhea infections, 5.6 million Syphilis infections and 143 million trichomoniasis infections[5]. The most common STI virus is genital herpes simplex virus infection (affecting around 500 million people worldwide) and Human Papillomavirus

(HPV) infection (affecting 290 million women and up to around 500,000 cases of cervical cancer every year)[6,7].

In Indonesia, based on the Integrated Survey and Biological Behavior (STBP) Report by the Indonesian Ministry of Health (2011), the prevalence of sexually transmitted diseases (STDs) in 2011 was 179% of gonorrhea and chlamydial infections and 44% of syphilis. The case of Human Immunodeficiency Virus (HIV) and Acquired Immunodeficiency Syndrome (AIDS) for the last eight years starting from 2005 - 2012 showed an increase from 859 cases to 21,511 cases. The newest AIDS issues increased from 2,639 to 5,686 cases[8].

General Hospital of Undata reported that there were 102 cases of HIV in 2018. There were 68 cases for male and 34 cases of female (8). Therefore, the researcher conducted an analysis related to "Risk Factors of Sexually Transmitted Infections (STIs) in Patients of Internal Medicine and Dermatology & Venereology Polyclinic at Undata General Hospital of Palu in 2018".

Materials and Method

This research study is quantitative using an analytical design with a case-control study approach. The dependent variable was sexually transmitted infections (STIs), while the independent variables were gender, age and marital status. The location of this study was in the Medical Record Room of the Undata General Hospital of Palu from 23 February to 8 March 2019. The populations in this study were all patients who got medical record data by visiting and conducting examinations at the Internal Medicine and Dermatology & Venereology Polyclinic in Undata General Hospital of Palu in 2018. The total population was 16,373 patients. All 152 samples were collected using a simple random sampling method. The sample was divided into 2 parts; 38 case samples and 114 control samples. Chi-square test was applied to analyze the data with a significance level (α) of 5% and confidence level (CI) of 95%.

Results

The distribution of respondents' characteristics according to age, sex, marital status and sexually transmitted infections (STIs) can be seen in table 1.

Table 1 explains the greatest number of respondents of STI sufferers. The greatest numbers are 35 people in the age group of 20-24 years old and the least are in the age group of 15-19 years old and 30-34 years old. The biggest numbers of respondents who suffer STIs are male with 97 respondents. The respondents who suffer STIs have a status of married with 84 people.

Table 1. Characteristics of Respondents

Variable	n	%
Age (Year)		
15-19	18	11,8
20-24	35	23,0
25-29	21	13,8
30-34	18	11,8
35-39	19	12,5
≥ 40	41	27,0
Sex		
Male	97	63,8
Female	55	36,2
Marital Status		
Not Married	68	44,7
Married	84	55,3
Sexually Transmitted Infections		
HIV/AIDS	25	16,4
Anogenital (Venereal) Warts	10	6,6
Herpes	3	2,0
Other	114	75,0

Table 2 also explains of the 38 respondents who experienced STIs there are 52.6% of respondents with low-risk sex and for high-risk sex and have a lower value of 47.4%, whereas of 114 respondents who did not experience STI, there is 67.5% with low-risk sex and 32.5% have high-risk sex. The results of the statistical test found an OR of 1.873 in 95% CI 0.887-3,959, meaning the female have a risk of sexually transmitted infections 1,873 times greater than the male. Because OR> 1, female was a risk factor for STI incidents. But, because the lower limit value of the sex does not reach the value of 1, the study of sex has not been able to explain the meaningful relationship between sex and the incidence of sexually transmitted infections.

Table 2 explains of the 38 respondents, who experienced STIs, 65.8% occur in respondents with high-risk marital status and 34.2% with low-risk marital status. From the 114 respondents who did not have STIs, 62.3% are the highest scores and respondents with low-risk marital status. Moreover, there are 37.7% of respondents with high-risk marital status. The results of statistical tests showed OR of 3.175 and 95% CI (1,471-6,857), meaning unmarried respondents have a risk of 3.175 times greater having sexually transmitted infections compared to respondents who are married.

Because the value of OR> 1, the unmarried marital status is a risk factor for the incidence of sexually transmitted infections.

Table 2. Risk Factors for Sexually Transmitted Infections (STIs) in Patients of Internal Medicine and Dermatology & Venereology Polyclinic in Palu 2018

	Occurrence of Sexually Transmitted Infections (STIs)				Total	OR (CI 95%)
	Cases		Control			
	n	%	n	%		
Age						
High risk	21	55,3	32	28,1	53	3,165 (1,482-6,761)
Low risk	17	44,7	82	71,9	99	
Sex						
High risk	18	47,4	37	32,5	55	1,873 (0,887-3,956)
Low risk	20	52,6	77	67,5	97	
Marital Status						
High risk	25	65,8	43	37,7	68	3,175 (1,471-6,857)
Low risk	13	34,2	71	62,3	84	

Discussion

The results of the analysis indicated the age was one of the risk factors for the incidence of sexually transmitted infections (STIs). Age was an important variable in influencing one's activities. In carrying out sexual activities, more mature people have better consideration than younger ones[9,10].

Sexuality is closely related to health at an older age. As previously reported, the prevalence of erectile difficulties was higher at an older age as younger age[11,12] so that older adults with medical problems could affect sexual function. This indicated that young age had a more active sexual activity compared to older age, seen from the health status and frequency of having sex[10,13].

Young people are more vulnerable to be infected by STIs. The reason is that young people tend to change partners, keep up with the trends of today's youth, coupled with the vulnerability of immature reproductive organs and lack of awareness for the cleanliness of intimate organs. Hence, the risk of STI incidence is higher[14,10]

Small opportunities to get marriage in young age and the rapid flow of information have been the influence of sexual behavior in teenagers. It often stimulates a teenager's sexual hormones. These stimuli encourage teenagers to have sex before marriage. During adolescence, sexual hormones begin to become active. This triggers teenagers to engage in sexual behavior since they sense an interest to the opposite sex[6,15].

Sex is also a factor in sexually transmitted infections (STIs). Many cases of STIs in women are asymptomatic, which results in slow diagnosis and treatment[16]. The manifestation of clinical symptoms of sexually transmitted diseases in men is more evident, so it provides an opportunity for patients to use advanced health services. The cause is the differences in anatomical structures of certain organs[17,16].

Based on the results of the statistical test analysis, female sex was more at risk of suffering from sexually transmitted infections compared to men[18,1]. This was because women were physically-disproportionately affected by all sexually transmitted infections. The rate of transmission from men to women was higher than from woman to man; partly because of exposure to columnar epithelium[19]. However, signs of infection in women can remain hidden until it is too late to take care. In addition, women were more vulnerable to infection due to gender-based power inequality[20,21].

Most infection incidents around the world tend to occur in women due to a number of factors like transmission of male to female STIs,which is more likely to happen than transmission of women to men. Sex trafficking is also one of the aspect since women want to earn money or to support themselves as well as

lack of protective equipment controlled by women and the initial phase of STI that often causes no symptoms in women[22].

The incidence of STIs is higher in people who are not married, divorced or people who are separated from their families compared to married people. Transmission of STI disease usually occurs because of frequent sexual intercourse. Marriage should be regarded as a sacred relationship that must be maintained. Therefore, the status of marriage is a barrier for a person to have sex freely and if the status is not married, it can be easier to bring a person to a menacing sexual behavior, which does not consider the danger of STIs[17,12].

Based on the results of statistical test analysis, it showed unmarried respondents were more at risk of suffering from sexually transmitted infections than to married respondents. Unmarried and divorced/separated people from their family had more sexual issues and lead them to have a sexual partners; increasing the risk of the incidence of sexually transmitted infections (STIs)[15,25].

Marital status is related to deaths from HIV, which is one of the sexually transmitted infections. Divorced and separated people have a higher risk of dying from STIs than married people. Single/never married people are more likely to die of STIs than married people[23,15].

Marriage gives limits and many other benefits those other statuses. One of the main benefits of marriage is a stable sexual activity. The term sexual activity describes a group of individuals connected through sexual contact[20,24]. Sexual activity plays an important role in the dissemination and acquisition of sexually transmitted diseases. In simple terms, individuals with more sexual partners are at higher risk of contracting sexually transmitted diseases (including AIDS) than those who have a reliable partner. This means that unmarried and divorced/separated people from their family have a wider sexual connection, which contributes to have more sexual partners and in turn increases the risk of STIs & HIV/AIDS and then dies of it[26]

Conclusion

The study concluded that gender and marital status were risk factors for the emergence of sexually transmitted infections (STIs) in patients of Internal Medicine and Dermatology & Venereology polyclinic at Undata General Hospital of Palu. Thus, it is expected that there will be prevention efforts from the government, the community and the family. The attempts in this regard, one of them is promoting condom use for both men and women.

Zinc and Probiotic Combinations: Balancing Blood Sugar and Blood Fats in Children OBES and Bows

Rudy Hartono[1], Aswita Amir[1], Agustian Ipa[1], Rusli[2]

[1]Nutrition of Department, [2]Pharmacy of Department, Makassar of Health Polytechnic, Indonesia

Abstract

The prevalence of fat and obesity in the world population increases with the times. Fat and obesity increase not only in adulthood but also in children and toddlers. This is due to the increasing social and economic status accompanied by technological advancements so that all clothing and food needs will be easier to obtain without having to spend a large amount of energy, so fat accumulation increases without significant activity which causes everyone to become fat and obese. This study aims to analyze the effect of zinc and probiotic supplementation (supplement is Lactobacillus casei) on blood sugar levels, total cholesterol, triglycerides, LDL (Low-Density Lipoprotein) and HDL (High-Density Lipoprotein). This type of research is an experiment with pre-post test design. The population is all children in the Perumnas I and IV Elementary Schools of Makassar City. The sample used was all obese and obese children as many as 8 students. The supplements used are zinc and L. casei, which are given once a day on school days. The research variable used was a serum sample derived from blood in mg/dl units and analyzed at the Tajuddin Chalik General Hospital Makassar. Data analysis uses paired t test. The results showed that there was a significant decrease in blood sugar levels while total cholesterol, triglyceride, LDL and HDL levels did not decrease significantly. Suggestions for using zinc and L. casei supplements in obese and obese children should be balanced with exercise so that triglyceride levels can drop to normal levels.

Keywords: *The combination of zinc and L. casei, blood sugar, blood grease.*

Introduction

Obesity is now an important problem in the world of health. The impact on health problems is huge. Obesity increases the risk of heart disease, diabetes mellitus (diabetes), joint disease and also cancer. If it occurs in children, obesity can also cause other problems that adversely affect the child's quality of life such as sleep disorders and impaired foot limb growth. In addition, in social life, obesity makes people feel less confident. Many people compete to go on a diet to maintain ideal body shape. It is quite difficult for someone to restore their ideal body weight when they are obese. Therefore, the intervention must actually begin when still in childhood. Several studies have shown that children and adolescents who are overweight, are twice as likely to be obese as adults compared to children who were not obese as a child. Maintaining an ideal body weight during childhood and adolescence can reduce the risk of obesity in adulthood. Unlike adults who can choose food, children and adolescents are more influenced by the environment when choosing food. In children, the main factor causing obesity is parents who provide food in excessive portions. This will cause the process of gaining weight very quickly. Parents play an important role in choosing foods to be consumed by children and regulate the daily physical activity of children. The results of research on obese and obese children who received zinc supplements showed blood sugar levels dropped significantly ($p < 0.05$), but those who used L. casei supplements dropped not significantly ($p > 0.05$) 7. Research conducted on obese and obese children who

get zinc and L. casei significantly decreased cholesterol levels (p <0.05) on total cholesterol levels 5,6,7. For triglyceride and LDL levels the use of zinc and L. casei did not decrease significantly (p> 0.05). HDL levels in obese and obese children were significantly decreased (p <0.05) that received zinc supplements and dropped not significantly (P> 0.05) in children who received L. casei7 supplements. Based on the results of these studies whether the combination of zinc and L. casei can reduce blood sugar levels when, total cholesterol, triglycerides, LDL and HDL in a balanced way?.The purpose of this study: to analyze the effect of a combination of zinc and L. casei on the decrease in blood sugar levels when, total cholesterol, triglycerides, LDL and HDL in a balanced way.

Material and Method

This research is an experimental research with pre post test only design. This research was conducted in 2018. The population was all obese and obese students in Perumnas I and IV Elementary Schools, while the samples were grade 2 and 6 students who were obese and obese and healthy, Bugis and Makassarese, residing in Makassar City. The number of samples as many as 8 people. Primary data that is anthropometric data, nutritional intake and levels of blood sugar, total cholesterol, glycerides, HDL and LDL will be collected before and after the intervention for 1 month. Secondary data in the form of sample characteristics were collected at the same time. As much as ± 3 cc of blood drawn in the sample. After that centrifuged to get the serum. The serum was examined using Cobas C111 made by Roche to determine levels of blood sugar, Total cholesterol, Glyceride, HDL and LDL each in mg/dl units at the Tajuddin Chalik General Hospital Laboratory Makassar. The analysis test used paired 2-sample t test with the data requirements normally distributed using the Shapiro Wilk test. Data is presented in tabular form with narrative description.

Findings: The table above shows that observations on body weight, height, nutritional intake in this case intake of protein (p> 0.05), fat (p> 0.05), energy (p> 0.05) and zinc (p> 0.05) as a control variable in this study did not show differences. This shows that there is no difference in nutrient intake, body weight and height, meaning that the variable of nutrient intake and weight are controlled. Based on the results of this study indicate that.

Table 1: Distribution of Changes in when blood sugar Profile, Total Cholesterol, Triglycerides, LDL and HDL in Fat Children and Obes who Obtain Combination of Zinc and L. Casei Supplements in SD Inpres Perumnas I and IV Makassar City in 2018

Suplement	Grade (mg/dl)		t	p
	Before	After		
When blood sugar	99,88±12,62	85,88±8,95	2,98	0,021
Kolesterol Total	190,13±37,29	181,5±40,34	0,747	0,480
Trigliseride	221,37±106,52	181,5±97,96	0,967	0,366
LDL	104,75±27,32	102,03±28,72	0,356	0,806
HDL	49,25±5,65	47,63±7,52	0,492	0,638

Based on table 1 above shows that there was a significant decrease in blood sugar levels (p <0.05) from an average of 99.88 to 85.88 mg/dl, for total cholesterol levels dropped from an average of 190.13 to 181 .5 mg/dl, triglycerides decreased from an average of 221.37 to 181.5 mg/dl, LDL dropped from an average of 104.75 to 102.03 and HDL dropped from an average of 49.25 to 47.63 mg/dl which was statistically significant decrease (p> 0.05).

Discussion

The use of probiotics has long been used to make fermented milk products. Probitik is a microorganism in the form of bacteria that is given in a sufficient amount to provide health benefits to the host[15]. Bacteria that are commonly used are Lactic Acid Bacteria (BAL) for fermentation such as milk fermented foods, cheese and plant-based foods[13,14]. This is because the administration of L. casei which functions to inhibit the enzyme alpha

glucosidase found in intestinal microphiles as explained by Jain and Nerves (2010) that BAL class bacteria can act as inhibitors of the alpha glucosidase enzyme and can cause a decrease in blood glucose levels in mice so that it can applied to humans. The work of zinc also synergizes together with L. casei to reduce GDS levels in obese and obese children so that it can be used as a prevention in increasing the body's resistance in counteracting free radicals.[11] Probiotic strains of Lactobacillus casei Shirota are lactic acid bacteria that have benefits for increasing the immune system, as antioxidants and have the ability to reduce cholesterol levels. Some recent research results indicate that shows that zinc is an important nutrient in the incidence of obesity. Recent studies report that adults with a history"Yo-Yo" syndrome (gradually decreases, then gets worse)[10]. Zinc supplementation is significantly helpful[12]. In one study, zinc levels in obese and obese subjects were inversely proportional to their body mass index, this shows that the important role of zinc in the development of obesity. In general, the higher the body mass index, the lower the zinc[9]. The mechanism of cholesterol reduction can occur because the lactic acid present in yogurt can degrade cholesterol into coprostanol. Coprostanol is a substance that cannot be absorbed by the intestine. Thanks to yogurt, the coprostanol and the remaining cholesterol can be excreted with feces. In other words, the amount of cholesterol absorbed by the body becomes low. A report on this subject explained that the reduction of cholesterol by lactic acid bacteria (Lactobacillus) could reach around 27-38%[8] ·High fat consumption will increase sterols in the large intestine and increase secretion of bile salts, which will then be metabolized by bacteria in the intestine to produce carcinogenic compounds (cancer triggers). Cholesterol in food through the stomach to the duodenum and in the intestine in the triacylglycerol oil phase[16].

Bile acids are absorbed from the bottom of the ileum and back to the liver. This is hepatic circulation. Collection of bile acids in the liver approximately 3.5 grams is circulated 6-10 times per day. Every time 1%, which is about 500 milligrams/day, escapes absorption and is excreted through feces. Furthermore the body's cholesterol is secreted through the intestine by the intestinal wall. Bile salt is wasted through feces and causes more cholesterol to be needed to synthesize bile salt again, thereby reducing body cholesterol levels[17]. The results showed that there are several benefits of probiotics in the body that play a role in reducing cholesterol levels, where bifidobacteria produce niacin which contributes to the reduction in cholesterol. The cholesterol-lowering effects of lactic acid bacteria (LAB: Streptococcus, Lactobacillus and Bifidobacterium) are well known. Lactic acid bacteria are found in yogurt. These bacteria form colonies and create an environment in the digestive tract in such a way that can prevent the growth of pathogenic bacteria that enter the body. This study shows the results that LDL levels in obese and obese children do not decrease significantly if given a supplement of zinc, L casei and a combination of zinc + L.casei, if it refers to the significance value, obese and obese children who get L. casei supplements have a decrease in value the lowest significant. This means that zinc and L. casei can reduce LDL levels in fat and obese[18,19].

This is consistent with the results of research which resulted that the L. casei strain Shirota strain reduces LDL levels in rodents (mice)[20]. The results showed that high significance in overweight and obese children who received zinc and L. casei combined supplements had a significant decrease in HDL levels. Lactic acid bacteria can also prevent urinary tract infections, reduce the risk of cancer or gastrointestinal tumors and other organs, reduce blood serum cholesterol levels, reduce the risk of coronary heart disease, stimulate the formation of the immune system, help sufferers of lactose intolerance in consuming milk and facilitate the elimination of waste defecate. Lactic acid produced by bacteria with a pH value of 3.4-4 is sufficient to inhibit a number of destructive bacteria and spoilage of food and beverages. However, during the fermentation process, it not only produces lactic acid and lactobacillin. Also produced certain compounds that can increase the organoleptic value of food and drinks, including tastes and odors that invite taste and improve appearance. The process of forming cholesterol and carcinogens (tumor-triggering compounds) starts from fat which will turn into bile acids which then become a series of enzymes. Then change the carcinogen into a carcinogen, which among others triggers colon, breast, prostate and pancreatic cancer. The process of forming bile acids from fat is stimulated by fecal bacteria or coli bacteria that come from feces or feces.[2,3] But in the presence of lactobacillin, the faecal bacteria become inactive so that the process of changing fat into bile acids also stops. Another compound of lactate bacteria is NI (not yet identified or unknown). However, this compound has been known to play a role in inhibiting the formation of cholesterol. NI works by inhibiting the enzyme 3-hydroxy 3-methyl glutaryl

reductase which will convert NADH to nevalonic acid and NAD. Thus, a series of other compounds that will form cholesterol are also inhibited. Because it can be said that the presence of foods and beverages that are naturally acidified by the fermentation of lactate bacteria, can help their consumption prevent cholesterol and cancer. The role of Zn not only affects the antioxidant enzymes, but Zn[1,2]also influences blood glucose levels[2]. Several previous studies explain the administration of Zn at different doses beneficial for the blood glucose levels of hyperglycemic rats. A 2014 study gave Zn a dose of 5 mg/kg body weight (BB) in hyperglycemic mice for 3 months and proved that Zn played a role in stimulating protein kinase B phosphorylation and activating glucose metabolism so that blood glucose levels decreased[3,4].

Conclusion

By supplementing the combination of zinc and L. casei, reducing blood sugar levels when significant under normal circumstances, there was a decrease in levels of total cholesterol, triglycerides, LDL and HDL which were not significant, where the decrease in triglyceride levels had not reached normal levels. We recommend using zinc and L. casei supplements with appropriate activities and adequate fat intake.

Conflict of Interest Statement: There is no conflict of interest between the researcher and the investigator.

Source of Funding: This study gets the cost of a superior research scheme from Makassar Health Polytechnic. Thank you to the Director of Makassar Health Polytechnic.

Ethical Clearance: The Makassar Health Polytechnic Research Ethics Commission has issued research ethics based on the protocol reviewed by reviewers.

Adolescents' at Risk with Crime Risk Behavior in Malaysia: A Correlation Analysis

Samsiah Mohd Jais[1], Mohammad Nasir Bistamam[1], Nor Hafifah Abdullah[2], Nurul Hasyimah Mat Rani[3]

[1]Senior Lecturer, Faculty of Human Development, [2]Faculty of Human Development, [3]Senior Lecturer, Faculty of Human Development, Sultan Idris Education University, Malaysia

Abstract

The purpose oft his study is tome a sure the relationship of crime risk behaviors among adolescents with social support (family, peer, school), socioeconomic status, resilience, coping skills, empathy, aggression, academic achievement, truancy and involvement in school activity. This survey study was carried out using the In strum en Remaja Berisiko Jenayah (IRBJ) that was developed from this study. The face validity value of the IRBJ is .91 and the value of the Cronbach alpha reliability is .75. The survey involved 300 students from Klang (urban areas: 150) and Kedah (rural areas: 150). The survey data was analyzed using correlation analysis. The results of the survey show that there is a significant relationship between social support from family, social support of peer, social support from school, resilient, coping skills, empathy, aggressive, truancy, academic achievement, involvement of school activities and crime risk behaviors. The information on adolescents' characteristics at risk of crime risk behavior and the empirical nature of exploration is expected to open a new chapter in understanding the development of adolescents in various aspects, particularly the criminal aspects of juvenile behavior in Malaysia.

Keywords: *Social Support (Family, Peer, School); Socioeconomic Status; Resilience; Coping Skills; Empathy; Aggression; Academic Achievement; Truancy; Involvement in School Activity; Crime Risk Behavior; Adolescent.*

Introduction

Problem Statement: For every country, children and adolescents are future national assets. In Malaysia, we put greats hope on them to continuing survival of this country's prosperity and success to become a well-developed country by 2020. So, their well-being and success in life and education is paramount to achieve the national goals. However, there is a small group of children and adolescent who are caught up in a variety of social problems and crime even though majority of children and adolescents has been successful in various fields such as education, sports, arts and soon.

According to statistics released by Ministry of Education Malaysia, truancy recorded the highest number of discipline problem committed by students in 2017, followed by smoking, criminalized and bullying [1]. This finding was parallel with finding by Health Ministry study which they found that 16 per cent of the country's teenagers were involved in bullying,13 percent smoked, seven percent in sexual activities and six percent in suicide attempts[2]. Besides, research has shown that an average of 18,000 teenage girls in Malaysia get pregnant each year and out oft his number, 25% orabout 4,500 cases involve pregnancy out of wedlock[3]. This further explains why today's juvenile and school crime issues need to be taken seriously by the government.

Factor Contributed to Crime Risk Behavior: Many studies have been conducted to understand the issues related to crime risk behavior. In the past years research, they found that there are several factors that give rise to crime risk behavior which are socials up port, socioeconomic status (SES), psychological aspect, truancy, academic achievement and involvement in school activity[4-6].

Currently in Malaysia, most of the study that had been conducted tend to highlighted only a single issue

related to crime risk behavior in a single study. These studies that had been conducted investigate the role of these factor which are social support, SES, psychological aspect, truancy, academic achievement and involvement in school activity separately[7-14].

Past research revealed that crime risk behavior has a significant relationship with social support from family[15-16], social support from peer[17-18], social support from school [18-19] and SES[20-21]. Moreover, there are several psychological aspects that give rise to crime risk behavior among adolescents which are low level of resilience[5, 22], inefficiency of copings kills[23-24], low level of empathy[25-26] and high level of aggression[4, 10].

Lastly, at the school level, there are three factors contributed to crime risk behavior that can be identify by school counselor orc lass's teacher which are low academic achievement[27-28], low involvement in school activity[29-30] and high involvement in truancy[12, 31].

Methodology

Sample: In this study, 300 secondary school students in standard 1 and 2 (13 and 14 years old) were recruited through purposive random sampling technique. All sample came from two area which were Klang (urban areas: 150) and Kedah (rural areas:150).

Procedure

Permission was obtained from Education Planning and Research Division, State Education Department and principals of the school that had been selected. Before we collect the data of this study, we explained about any risk or benefit that they will get from this study and after that, we obtained the consent from the participant. We admitted the questionnaires in quite space that had been set up by the school and took up around 45 minutes to complete.

Measure: All construct in this study were measured using self-report measured known as Instrumen Remaja Berisiko Jenayah (IRBJ)[32] that was adopted from Instrumen Remaja Berisiko[33]. This instrument consists of 87 items in total with 12 constructs and in Malay language which are social support (family, peer, school), socioeconomic status, resilience, coping skills, empathy, aggression, academic achievement, truancy, involvement in school activity and crime risk behavior. For this instrument, from the face validity analysis that had been conducted, it shows that this measure has face validity (.91). We continue with reliability analysis of the measure and it was conducted through internal consistency analysis. Overall Cronbach alpha value is .75. DeVellis[34] said that according to general rule of thumb, the ideal Cronbach alpha value are above .70 (good), .80 (better) and .90 (best).

Data Analysis: Correlation analysis was performed to measure there lationship between all construct in this study and was conducted using SPSS version 23.

Results

Correlation Analysis: The relationship between all variables in this study was investigated using Pearson product- moment correlation coefficient and can be seen in Table 1. A correlation of 0 indicates no relationship at all, a correlation of 1.0 indicates a perfect positive correlation and a value of -1.0 indicates a perfect negative correlation. According to Cohen [35], he suggests that the correlation strength between two variables can be interpret as .10 to .29 (weak), .30 to .49 (medium) and .50 to 1.00 (large). From the analysis that had been conducted, there was a large, positive correlation between social support from family with resilience (r = .56) and coping skills (r = .55), between social support from peer with social support from school (r = .52), between socials up port from school with resilience (r=.52) and between resilience with coping skill (r = .72) and empathy (r =.58).

Besides, there also medium, positive relationship between social support from family with social support from peer (r = .38), social support from school (r = .43) and empathy (r = .30), between social support from peer with resilience (r = .49), coping skill (r = .45), empathy (r =.47) and academic achievement (r=.30), between socials up port from school with coping skill (r = .47), empathy (r = .48) and academic achievement (r = .37), between academic achievement with socioeconomic status (r = .32) and resilience (r = .33), between empathy with coping skill (r = .49) and academic achievement (r = .36) and lastly between aggression with truancy (r = .30) and crime risk behavior (r =.42).

Next, there is weak, positive relationship between socioeconomic status with social support from peer (r=.12), aggression (r=.13) and truancy (r=.23), academic achievement with social support from family (r=.22) and copings kill (r=.27), between truancy and crime risk behavior (r = .26) and lastly between involvement in

school activity with social support from family (r= .21), social support from school (r = .18), resilience (r = .20) and coping skill (r = .17).

In addition, there is medium, negative relationship between resilience and aggression (r=-.30) and between crime risk behavior with social support from peer (r = -.30) and social support from school (r=-.31). Moreover, there is weak, negative relationship between aggression with social support from family (r = -.22), social support from peer (r = -.22), social support from school (r = -.28), coping skill (r = -.20) and involvement in school activity (r = -.23), between truancy and academic achievement (r = -.22), between involvement in school activity with socioeconomic status (r = -.14), truancy (r = -.29) and crime risk behavior (r = -.25) and lastly between crime risk behavior with social support from family (r = -.24), resilience (r = -.25), coping skill (r = -.15) and empathy (r =-.24).

Table 1: Correlation between All Constructs

Construct		1	2	3	4	5	6	7	8	9	10	11	12
1	Social support fromfamily	1	.38**	.43**	.06	.56**	.55**	.30**	-.22**	.22**	-.08	.21**	-.24**
2	Social support from peer		1	.52**	.12*	.49**	.45**	.47**	-.22**	.30**	.04	.06	-.30**
3	Social support fromschool			1	.07	.52**	.47**	.48**	-.28**	.37**	.02	.18**	-.31**
4	Socioeconomic status				1	-.01	-.01	.09	.13*	.32**	.23**	-.14*	.07
5	Resilience					1	.72**	.58**	-.30**	.33**	-.03	.20**	-.25**

10	Truancy										1	-.29**	.26**
11	Involvement in school activity											1	-.25**
12	Crime risk behavior												1

Discussion

In this current study, we only focused on our variables of interest as variables that have a relationship with crime risk behavior. Future studies may investigate the effects of other predictors or variables on crime risk behavior. Besides, this is cross-sectional study, future study may replicate this study by conducting a longitudinal research. Another thing is this study use Pearson correlation analysis to analyses the data. So next research can use more advance statistical analysis to investigate the significant predictor to crime risk behavior such as by using regression analysis, path analysis or Structural Equation Modelling (SEM). From the finding, we recommend school counsellors and psychologists who working with adolescents at schools or other institutions to undertake protective and preventive work to increase the social support that students receive from family, peers and school. Many programs can be held such as group guidance programs for peers and psycho educational programs to develop relationships between counsellors, students, families and teachers.

Ethical Clearance: Ethical procedure of this study was approved by the Educational Planning and Research Division, Ministry of Education Malaysia. Besides, the inform consent was acquired from the participant who agreed to participate in this study.

Conflict of Interest: There is no conflict of interest in this research.

Source of Funding: This study was funded by the Research Management and Innovation Centre, Sultan Idris Education University through the Top Down Grant

Scheme (Fundamental) 2016 through a research grant with code UPSI/PPPI/PYK/TOPDOWNKPT/645.3(18).

Influence of Superadded Fetal MRI on Prenatal Ultrasonography in Assessment of Fetal Ventriculomegaly

Sara Mahmoud Ragae[1], Mohamed Mourad A.[1], Moustafa Mahmoud R.[2]

[1]Radiology Department, Minyauniversity, Minia, Egypt, [2]Obstetrics and Gynecology Department, Cairo University, Egypt

Abstract

Background: Prenatal diagnosis in IVM is considered a challenge with great impact upon management.

Objectives: Estimating the value of adding fetal MRI to sonographically diagnosed IVM.

Patients and Method: Data were gathered prospectively from 60 pregnant women with ultrasound-diagnosed IVM referred for MRI between April, 2017 and September, 2018, followed by postpartum neonatal MRI brain examination to non-terminated, live birth cases.

Results: Of the sixty fetuses with IVM, Fetal MRI added findings to prenatal U/S imaging in 14 cases (23%) and most of these findings were identified in fetuses with severe IVM (about 50%). No additional abnormalities were identified by fetal MRI in fetuses less than 24 weeks gestation. Callosal and septum pellucidum lesions accounted for most common significant fetal MRI additional findings with percent (28.6 % of the additional findings). Management was changed according to the additional findings where Increased rate of termination was more associated with cases with additional abnormalities rather than the isolated VM cases.

Conclusion: This study recommend fetal MRI for sonographically diagnosed IVM to guide the clinical management.

Keywords: *Fetal MRI, Fetal ventriculomegaly, prenatal ultrasound, Intrauterineventriculomegaly.*

Introduction

Cerebral ventriculomegaly (VM) is one of the most commonly detected fetal anomalies at the mid-trimester ultrasound [(1)]. The classification of VM has varied in published studies, mild (10–12 mm), moderate (>12–15 mm) or severe (>15 mm) is a commonly accepted categorization[(2)].

Ultrasound is a favorable screening modality for fetal CNS abnormalities. However,On U.S. usage; some limitations hinder proper diagnosis as maternal obesity, oligohydramnios, fetal head engagement in late pregnancy or acoustic shadowing by surrounding bony structures[(3)].

Fetal MRI is being increasingly used as a complementary tool to U.S. in fetal CNS abnormalities assessment[(4)].

The aim of this study was to detect the impact of acceding fetal MRI to sonographically diagnosed IVM regarding confirming the diagnosis as well as detecting additional anomalies that my affect the choice of management and the outcome of the pregnancy.

Patients and Method

This prospective study was approved by the ethics committee of our institution during the period between

Corresponding Author:

Radiology Department. Minya University, Minia, Egypt.
e-mail: dr.sararagae@gmail.com

April, 2017 and September, 2018. It included 60 pregnant women with their age ranging from 18 to 45 years & of gestational age ranging from 20 to 32 weeks at time of examination (sonographically and by MRI). This study was conducted in our radiology department for patients referred from the obstetrics and gynecology department. We performed fetal MRI to sonographically diagnosed fetal VM at the same setting with no time lag between the two modalities; followed by postnatal MRI brain to 15 (25 %) of our 60 cases, who weren't terminated & were live birth.

- Our Inclusion criteria were (2D/3D) Sonographically diagnosed IVM.
- Exclusion criteria were; MRI contraindication (as cardiac pace maker), Mother's refusal to do fetal MRI.

U/S technique: Sonographic examination was done in supine position using (Voluson E, Toshiba, Japan) with trans-abdominal transducer of a bandwidth 3.5 MHz associated with color Doppler added property.

MRI technique: MRI examination was performed on 1.5-Tesla MR scanner ((Ingenia 1.5 Tesla, Philips, Netherland) without maternal sedation. Mothers fasted 4 h before the examination. They were made to lie supine during the examination.

MRI was primarily performed, using a multi-channel phased array coil..An initial three plane localizer with single shot fast spin echo (TR 4960-TE 100 band width 50) is obtained to visualize the position of the fetus. Then neuroimaging examination was done for fetal brain imaging in three orthogonal planes (axial, sagittal and coronal plane)

Fetuses were imaged with a total scan time about 10-15 minutes in the following sequences:

- Single Shot Fast Spin Echo T2WI (SSFSE T2) which is useful to assess fetal anatomy and less susceptibility to fetal movements ..
- Gradient echo-planar T2-W images to detect hemorrhage. Images were acquired in 7 s, during a single maternal breath-hold, in the axial and coronal planes.

Postnatal MRI technique of the brain: MRI examination was performed on 1.5-Tesla MR scanner ((Ingenia 1.5 Tesla, Philips, Netherland) with infantile sedation. It was made in different pulse sequences and planes (sagittal T1WI, coronal T2WI, axial FLAIR and DWI) Image interpretation parameters:

- Ventriculomegaly was considered when atrial width equal to or greater than 10 mm, measured manually at the atria of the lateral ventricles at the level of the choroid plexus on an axial image in ultrasound and on coronal plane in MRI.
- VM was classified in to mild (10–12 mm), moderate (>12–15 mm) & severe (>15 mm) in both U/S and MRI modalities which was based on Gaglioti P et al 2005 and Yu-Han Huang et al 2013 classification.

Statistical analysis: Statistic Package for Social Sciences (SPSS v 17.0 for Windows, Chicago, IL) software was used for data entry and analysis.

Qualitative data were presented by numbers and Statistical significance was assessed using the chi square χ^2 test to compare differences between the two independent groups. Significance was interpreted as $p < 0.05$.

Results

Sixty pregnant females were enrolled in our study,80% of our pregnant females were above 35 years old which was statistically significant (p value =0.041) .

(Table I) is a comparison between MRI & U.S in degree of VM, showing agreement between the VM measurements of the ultrasound and the MR imaging with non-significant statistical difference between the VM grades in both modalities (of p-value about 0.105).

Regarding the gestational age (GA) of the involved fetuses, fetal MRI additional abnormalities & changing diagnosis were more pronounced after 24 weeks GA.

(Table II) shows a comparison between Fetal MRI & prenatal ultrasound with confirmatory Postnatal MRI to non-terminated & live birth cases (25%). In addition it showed the percent of each of the fetal MRI additional findings (23%), changed sonographic diagnosis (1.7%) & confirmed sonographic diagnosis (75%). The table also showed significance of adding fetal MRI modality to prenatal U.S. with p-value about 0.045.

The fetal MRI additional abnormalities in our study showed that the most commonly detected additional abnormalities were corpus callosal & septum pellucidumdysgenesis,followed by posterior fossa abnormalities and cortical malformations with their

percents (28.6%,21.5% and 21.5% of the additional findings) respectively. The additional abnormalities addressed by fetal MRI in the study changed the management, with higher rate of recommended termination by clinicians.

On the other side, the management strategy changed when no additional abnormalities were present in isolated VM cases in our study, where termination decision was limited to severely dilated ventricles.

The postnatal MRI was compared to each of U/S and Fetal MRI results, revealed results approaching those of fetal MRI with vast differences with U/S.;revealing superiority of fetal MRI upon U.S.in fetal VM assessment.

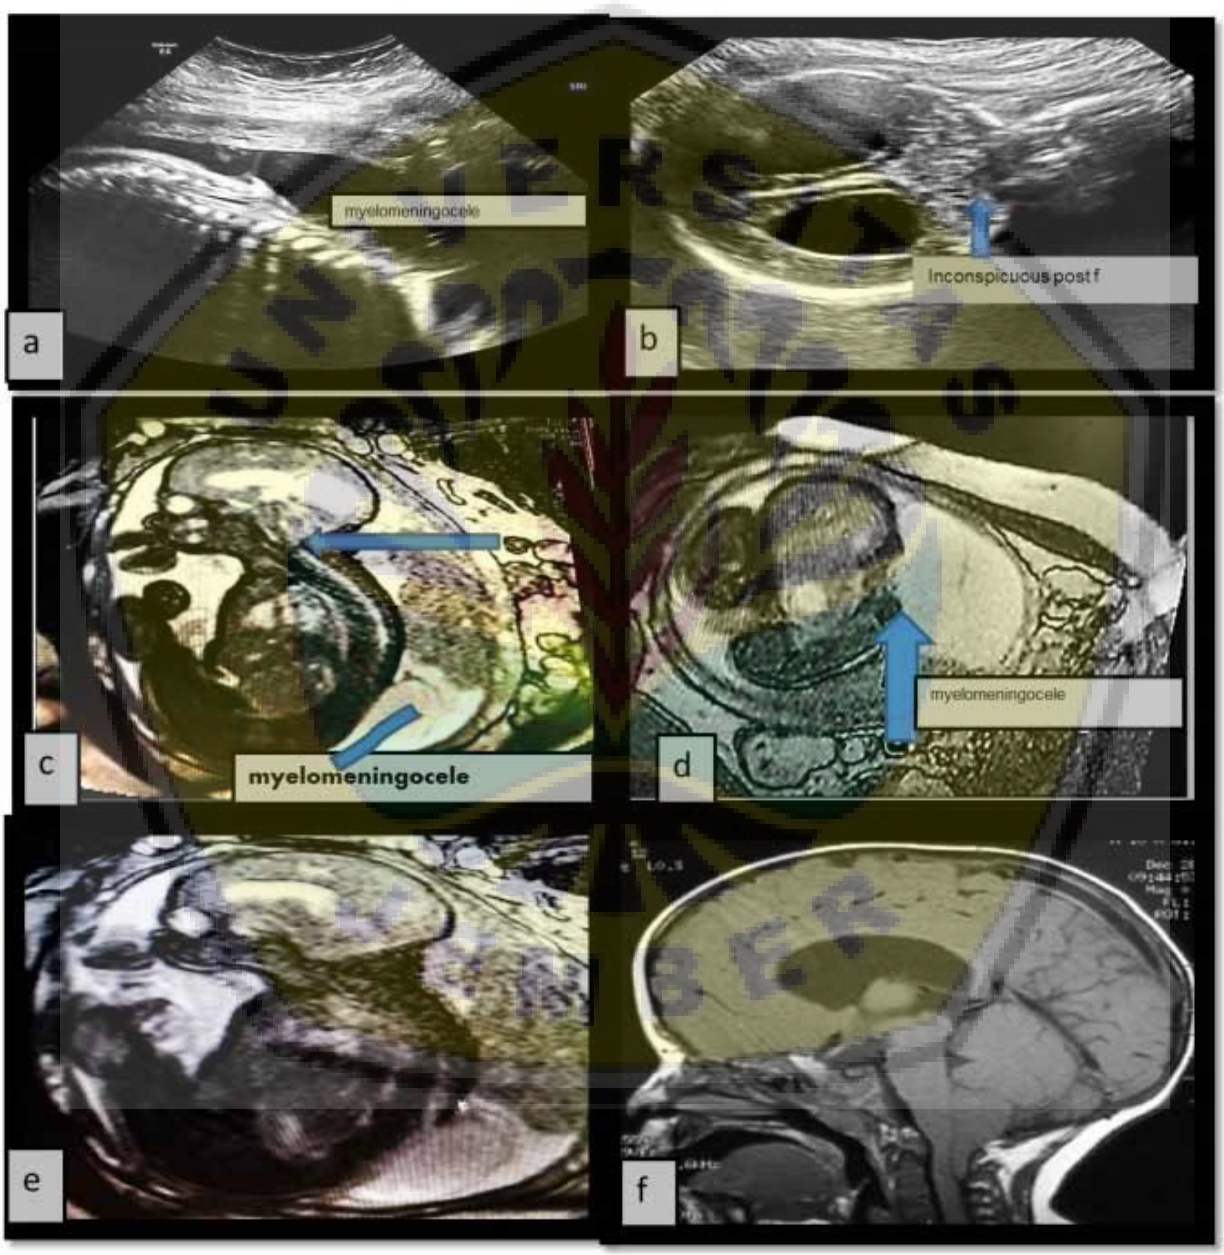

Fig. 1: Fetus 32 weeks GA (a) Sagittal U.S image shows myelomeningocele at the distal spine.(b) Coronal U.S image shows moderately dilated ventricles with inconspicuous posterior fossa suggesting Chiari II.(c),(d) and (e) MRI T2WI in sagittal and axial planes confirmed U.S findings with adding the degree of cerebellar tonsil herniation and the corpus callosaldysgenesis (d) postnatal MRI, showing the same findings as the fetal MRI.

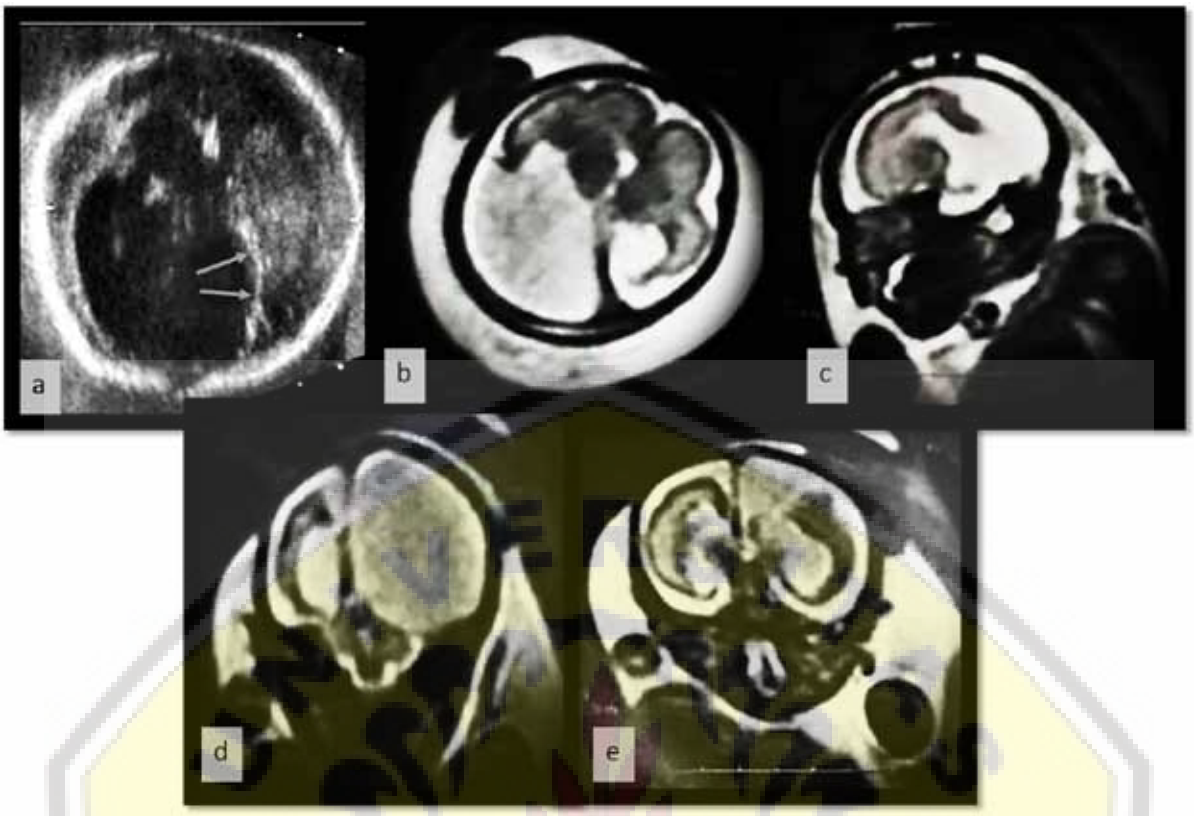

Fig. 2: Fetus of 26 weeks GA (a) axial U.S. image revealing asymmetrical ventricular dilatation, with bowed falxcerebri. (b,c, d, e) axial, sagittal & coronal cuts of the fetal MRI adding an inter-hemispheric cyst type I connected to one of the lateral ventricles associated with Corpus callosaldysgenesis.

Fig. 3: Fetus of 24 weeks GA, (a, b) U.S (axial & coronal images) showing moderate dilatation of supratentorialvetricular system. (c) Fetal MRI in sagittal plane reveal the cause as aquiductal stenosis.

Table I: VM degree by US versus VM degree by MRI .

VM. Degree U.S.	VM Degree MRI			P -value	Significance
	Mild	Mod	Severe		
Mild	26	7	0	0.105	Not significant
Moderate	0	15	3		
Severe	0		7		

Table II: Comparison between fetal MRI and prenatal ultrasound with significance of adding fetal MRI modality to prenatal ultrasound.

VM degree	U.S. Diagnosis	Fetal MRI			Postnatal MRI to non-termi-nated & live birth cases	P–value	Signi-ficance
		Confirm diagnosis	Additional Findings	Change U.S diagnosis			
Mild	Isolated VM or incomplete imaging findings		4		As fetal MRI	0.045	Signi-ficant
Moderate			2				
Severe			8				
Mild	I.V. hemorrhage			Mild VM, No I.V. hemorrhage	Just mild VM		
Mild,	Isolated VM or with U.S additional findings	27			As Fetal MRI		
Moderate,		16					
Severe		2					
No and Percent		(45) 75%	(14) 23.3 %	(1) 1.7%	(15) 25%		

Discussion

No doubt that VM is one of the most common abnormalities found on prenatal ultrasound [(5)]. Fetal MRI has been shown to be a useful adjunct to ultrasound in suspected fetal anatomic abnormalities and is increasingly used for fetal brain imaging [(4)].

In our study, we figured out that the maternal age was of significance; where 80% of the pregnant females in our cases were older than 34 years old which denoted that advanced maternal age is directly proportional to increased risk of congenital anomalies including CNS anomalies. That was equivalent to the study conducted by Hollier LM et al, 2000[(6)], who reported that advanced maternal age beyond 25 years old was associated with significantly increased risk of fetuses having congenital malformations.

Similar to previous studies, our results revealed that MRI measurements of lateral ventricle size were on average of 1-2 mm greater than US measurements. However, no notable changes were detected in VM grading to mild, moderate and severe relative to ultrasound. These results perfectly matched those of Nicholas Behrendt et al, 2016 [(7)].

We yielded Fetal MRI additional abnormalities in 14 of 60 fetuses (about 23%) with changing sonographic diagnosis in one case (1.7%) which was mis-interpreted by U.S as being IV hemorrhage & proved by fetal MRI to be just choroid plexus. This result was in rapprochement to the study addressed by Parazzini et al, 2012[(8)] who stated that Fetal MRI additional findings were identified in 19.5% of fetuses in his study.

Regarding our cases, fetal MRI additional findings were more pronounced after 24 weeks GA which was in coherence with and based on what was postulated by ACR, 2010[(9)], that fetal MRI study may give limited diagnostic information in early gestational age due to the small size of the fetus and fetal movement.

In our study, the commonest detected significant fetal MRI additional findings were callosal and septum pellucidum lesions (28.6%), followed by posterior fossa abnormalities (21.5%) and cortical malformation (21.5%). That was to a great extent affirmed by many previous studies as that of Tejaswi Kandula et al, 2015[(10)] who stated that all fetal MRI significant additional abnormalities were Callosal and septum pellucidum lesions, malformations of cortical development and periventricular abnormalities.

Something to be considered in our results is that fetal MRI additional findings were more notably detected in severe VM (about 50%); which was in accordance with the study conducted by Morris et al, 2007 [11] who found out that 58% of the fetuses with severe VM had prenatal MRI additional findings.

That perfectly explains why it is highly recommended to perform fetal MRI to all fetuses with severe IVM (VM >15 mm).

The results in our study has proven that presence of structural CNS abnormalities with VM has high association with termination of pregnancy rather than the degree of VM dilatation,which proves the fact that associated CNS abnormalities act as a better predictor of outcome rather than degree of ventricular dilatation. That coped with many other studies as that conducted by Y Li et al, 2011[12].

In addition to aiding in management and prediction of the neurodevelopmental outcome, we also noted that fetal MRI additional abnormalities give a clue about the possibility of recurrence & the need for genetic testing .An example for this is two cases in our study which were formerly diagnosed by U/S as severe VM and lissencephaly;On the other hand fetal MRI additional findings rendered the diagnoses as Fowler and Walker Warburg (HARDE) syndrome respectively; which were proved to be autosomal recessive syndromes with the imminent need for genetic testing.

We have performed confirmatory postnatal MRI for non-terminated & live birth cases (about 25%) which revealed the same fetal MRI findings with nil additional findings & only changed diagnosis in one case that was mistaken by Fetal MRI as cortical dysplasia with mild VM whereas it proved to be mild VM only with no associated cortical dysplasia by postnatal MRI. That rendered fetal MRI superior to prenatal U/S regarding fetal VM assessment.

Our results are at variance with those of other studies. It coped with the study conducted by ManalHamisa et al, 2013 [13] where she reported the fetal MRI specificity, positive & negative predictive values were of 100% as a complementary tool to U/S in Fetal CNs anomalies. However, that was against the study conducted by Malinger et al, 2004[14] who described that dedicated trans-vaginal neuro-sonography is equivalent to MRI in the diagnosis of fetal brain anomalies.

Limitations in our study included the relatively narrowed number of the performed postnatal MRI owing to the high ratio of termination decision and the incidence of still births or IUFD.

Our recommendations in the future is adding fetal MRI to prenatal ultrasound in fetal VM; where it is of great value and it greatly manipulates the fetal outcome.

Conclusion

Prenatal ultrasound is unquestionably favorable modality for fetal screening. However; Fetal MRI proved to be a perfect complementary tool to ultrasound especially in assessing fetuses with IVM, where it confirmed sonographic diagnosis with depiction of additional CNS abnormalities far beyond ultrasound that affect prognosis and clinical management, giving a clue about recurrence rate and the need for genetic testing.

Declarations: Ethics Approval and Consent to Participate: This study was approved by the Research Ethics Committee of the Faculty of Medicine at EL Minya University in Egypt on April 2017.

Consent for publication :All patients included in this research gave written informed consent to publish the data contained within this study according to our institution rules for ethics committee

Funding: This study had no funding from any resource.

Competing Interests: The authors declare that there is no conflict of interest.

Nurses Communication Model to Increase Patient Satisfaction: Evidence from Indonesia Hospital

Soliha[1], Ah Yusuf[2], Tiyas Kusumaningrum[3]

[1]Master Student of Faculty of Nursing, [2]Faculty of Nursing, Universitas Faculty of Nursing, [3]Faculty of Nursing, Airlangga University, Campus C Mulyorejo Surabaya, Indonesia

Abstract

Communication is an effective and important model in the field of nursing services because it is the basis for nurses to foster interpersonal relationships with patients and families. Communication is one way that allows nurses to deliver and receive messages so that maintenance activities can run well. Patient dissatisfaction with communication reduces patient loyalty and patient trust in nurses and decreases patient comfort levels. The purpose of this study is to develop a nurse communication model to improve patient satisfaction. This study uses an observational analytic design, consisting of 100 respondents consisting of 5 adult inpatient rooms with sampling techniques using simple random sampling. Data were analyzed using Partial Least Square(PLS). The results of the study show that nurse factors, patient factors and good social factors can increase the interaction that occurs between nurses and patients. Increasing nurses' communication skills can be influenced by good interactions between nurses and patients in the adult inpatient Syarifah Ambami Rato Ebu hospital. Good communication skills carried out by nurses will increase patient satisfaction as users of hospital services. For further researchers to continue the research by implementing a nurse communication module to determine differences in communication skills of nurses and patient satisfaction before and after being given a nurse communication module.

Keywords: *Nurse communication, Nurse-patient Interaction and Patient Satisfaction.*

Introduction

Communication is an individual effort to maintain and retain individuals to continue to interact with others and important components in nursing practice. Therapeutic communication is an important tool for fostering therapeutic relationships and can affect the quality of nursing services. One of the goals of therapeutic communication is to form an interaction, interdependence with the capacity to give and receive. A nurse in carrying out therapeutic communication must have the ability, among others: sufficient knowledge, adequate skills and good communication techniques and attitudes. The good communication skills of nurses are one of the success factors in implementing the nursing process which includes the stages of assessment, formulation of diagnoses, planning, implementation and evaluatioz [1,2]

Nurses must improve their performance in providing nursing care, especially when communicating with patients. Nurses are one of the health workers who are often in contact with patients so that patients communicate more with nurses. Lack of communication between hospital staff and patients is one reason for the general complaints of patients in hospitals. Patients are often dissatisfied with the quality and amount of information received from health workers[1,3]

The phenomenon that occurs in the Indonesia hospital is a breakdown of the communication of nurses, namely that the communication carried out by nurses has not yet fully paid attention to the techniques and

Corresponding Author:

Stikes Ngudia Husada Madura, Indonesia
e-mail: dsuhron@yahoo.co.id

stages that are good and right, so that the client lacks the correct information, or lacks the proper service. This is supported by the results of research conducted that, four nurses' errors were identified when implementing communication namely, non verbal (eye contact, facial expression and paralanguage), verbal (active listening and incorrect choice of words) and content (poor quantity and quality of information provided); and bad attitude (lack of respect and empathy)[2]

The results of a preliminary study conducted at Indonesia hospital, 9 patients (60%) considered that nurses were more focused on treatment activities so that they lacked attention and ignored the importance of communication. A total of 10 patients (66.7%) were still dissatisfied with nurse communication. Some things that also influence nurse communication are nurse factors, patient factors and social factors. A dissatisfied patient will, in turn, produce an attitude that is not compliant with all nursing procedures and medical procedures such as refusing to insert an IV, refusing to take medication, refusing to be compressed hot or cold and so on. Eventually, the patient will leave the hospital and look for quality services elsewhere.

The solution that can be done to increase patient satisfaction starts by increasing the ability and skills. These skills must be learned and trained continuously through the ability to learn independently, refresh and training. Besides that, an increase in the understanding of nurse and patient factors is also needed to improve nurse communication[2,3]. Interaction of nurses with patients must also be considered in order to form therapeutic communication between patient nurses. Enhancing nurses' communication skills will increase patient satisfaction[1,4]

Materials and Method

This study used an observational analytic design, consisting of 100 respondents consisting of 5 adult inpatient rooms with sampling techniques using simple random sampling. Variables in this study include nurse factors, patient factors, social factors, patient-nurse interactions and nurse communication in providing nursing care. The research instrument used a questionnaire. Research data were analyzed using *Partial Least Square(PLS).*

Findings

Description of Research Variables:

Table 1: Frequency distribution of nurse factors, patient-nurse interactions and nurse communication skills in developing nurse communication models to improve patient satisfaction

Variables	Good		Fairly		Less		Total	
	F	%	F	%	F	%	F	%
Nurse factors	16	16	54	54	30	30	100	100
Nurse patient interactions	19	19	44	44	37	37	100	100
Nurse communication skills	16	16	34	34	50	50	100	100

Based on table 5.4 shows that the development of nurse communication models in inpatients at ambulances in the ambassador rato ebu hospital in the nurse-patient interaction shows almost half are in the sufficient category at 44%. On communication skills, nurses showed half of them in the category of less, namely 50%.

Analysis of the measurement model (Outer model):

Table 2: Results of convergent validity on the development of the nurse communication model to improve patient satisfaction at the Syamrabu Bangkalan Regional Hospital in 2019

Variable Name	Indicator	Loading Factor	Category Category
Nurse Factor (X1)	X1.1 Perception	0.950	Valid
	X1.2 Decision	0.942	Valid
	X1.3 Actions	0.959	Valid
Patient Nurse Interaction (Y1)	Y1.1 Interaction	0.999	Valid
	Y1.2 Communication	0.983	Valid
	Y1.3 Transaction	0.995	Valid
	Y1.4 Role of	0.995	Valid
	Y1.5 Stress	0.975	Vlid
Communication Capability of Nurse (Y2)	Y2.1 Attending skill	0.919	Valid
	Y2.2 Emphaty	0.954	Valid
	Y2.3 Respect	0.832	Valid
	Y2.4 Responsivness	0.970	Valid

Table 2 can be known Indicators with outer loading values> 0.5 indicate that these indicators in the structure have met the validity test. The conclusion of this analysis is that the indicator above validly measures its latent variables and shows the criteria of goodness of a measurement model (outer model).

Table 3: Results of Average Variance Extracted (AVE), composite reliability and Cronbach's alpha model for developing nurse communication models to improve patient satisfaction in Syamrabu Bangkalan Hospital in 2019

No.	Variable	Cronbach's Alpha	Composite Reliability	Average Variance Extracted (AVE)	Description
1	X1	0.940	0.962	0.894	Reliable
2	Y1	0995	0996	0979	Reliable
3	Y2	0941	0957	0847	Reliable

Table 3 value composite reliability and Cronbach's alpha showed> 0.7 so that it can be concluded that all the latent variables (factors nurse, nurse-patient interaction and communication skills of nurses) have met the reliability test. The next check of convergent validity is the average variance extracted (AVE) value. AVE values above 0.5 are highly recommended. Based on the table above, the AVE value for all constructs or latent variables is above 0.5.

Testing the structural model (inner model):

Table 4: Hypothesis test results of the development model of nurse communication models to improve patient satisfaction at the Syamrabu Bangkalan Hospital in 2019

No.	Variable	T-statistic	Remarks
1	Effect of nurse factors (X1) on patient-nurse interactions (Y1)	2,916	There is an influence
2	Effect of patient-nurse interaction (Y1) on nurse communication (Y2)	2.897	There is an Influence of

Table 4 Nurse factors (t statistic 2,916> 2.0), so the nurse factor has a significant influence on patient-nurse interactions. Interaction of patient nurses (t statistic 2.897> 2.0) so that it has a significant influence on the patient's nurse communication skills.

Discussion

The Influence of Nurse Factors on Patient Nurse Interactions in Adult Inpatient Rooms Syarifah Hospital Rami Eato Bangkalan

Based on the results of the study showed the influence of nurse factors on nurse interactions. T-test results obtained t value t = 2.916 greater than 2.0. Nurse factors with variable perceptions, decisions and actions influence the interaction of nurse patients with indicators of interaction, communication, transactions, roles and stress. This is consistent with King's theory that nurse factors can influence patient-nurse interactions[1,2,4]

The most determining factor for nurses is an indicator of nurses' actions in providing nursing care with the value of cross loading 0.959. Indicators on nursing actions such as nurses ask complaints that are felt by patients, nurses provide information related to patients, deliver plans of action to be taken, ask permission when taking action and ask patient complaints when taking action. Nurses are required to carry out therapeutic communication in performing nursing actions so that patients or their families know what actions will be performed on patients in a way that nurses must introduce themselves, explain the actions to be taken, make a time contract for nursing actions[5,6]. One of the goals of communication carried out by nurses is to convey ideas or information to patients. By providing information carried out by nurses and delivering action plans to be taken, this is one way to equate ideas that are in the minds of nurses and patients. If this has been done, the nurse will be able to foster a trusting relationship and will make it easier for nurses to carry out and succeed in the treatment program[7,8,9].

There are 3 main elements that interact with each other in performance namely patient (Customer), nurse officer (customer service) and management (management). One of the important things in the interaction between patient nurses is the performance of health care workers or nurses. Interaction between officers and patients is a very deep thing that patients feel when receiving service[10,11,12,13]. This process is strongly influenced by the behavior of nurses in carrying out services or carrying out nursing actions. Communication by nurses when performing actions has optimal results to increase the interaction of nurses and patients[11,13,15].

The Influence of Patient Nurse Interactions on Communication Capabilities of Nurses in Adult Inpatient Rooms Syarifah Hospital Ambami Rato Ebu Bangkalan

Based on the results of the study showed the influence between interactions nurses to nurse communication skills. T-test results obtained t value = 2,897 greater than 2.0. Nurse-patient interactions with indicators of interaction, communication, transaction, role and stress indicators influence nurses' communication skills with attending skills, respect, empathy and responsiveness indicators. This is consistent with King's theory that improving nurses' communication skills can be influenced by patient-nurse interactions[14,16,17,18]

The most decisive interaction factor is an indicator of the interaction itself namely the patient's perception of the nurse's behavior when communicating with the patient during nursing care with the value of cross loading 0.999. Indicators of nurse interaction include nurses maintaining eye contact with patients, nurses showing honest faces, nurses facing patients, nurses bowing toward patients and nurses respecting patients.

Positive interactions conducted by nurses such as visual eyes that looked at the eyes of the patient while the nurse was next to the patient, proximity with speech were nurses standing at least as far as the patient's arm when interacting with the patient. This must be done by nurses to improve their communication skills[17,18].

Maintaining proper eye contact is a powerful way to communicate respect and that nurses pay attention to patients. The eyes that are not focused on the patient give meaning as loss of interest or attention. Proper eye contact is very different from staring. Staring is insensitive and sometimes breaks up. Nurses must always have eye contact readiness when interacting with patients. In depressed patients, they will always look down. If they momentarily look up and the nurse's eye contact does not look at the patient, then the patient will lose confidence in the nurse[20,21].

Nurses are required to have good interactions with patients. Presence or attitude really exists for patients, is part of the interaction. Nurses must not look confused; instead, the patient must feel that he is the nurse's main focus during the interaction. In order for nurses to play an active and therapeutic role, nurses must analyze

themselves which include self-awareness, clarification of values, feelings and being able to become a responsible model. All behaviors and messages conveyed by nurses should be therapeutic for patients. An interactive process between patients and nurses that helps patients overcome stress while living harmoniously with others, adjusting to something that cannot be changed and overcoming psychological obstacles that hinder realization[19,23,24] .

The results showed that the communication skills of nurses who made the most decisive contribution were indicators responsiveness with cross-loading 0.970 which included nurses paying attention to and responding to complaints submitted by patients, when patients had difficulties in facing their health problems nurses offered assistance without asking, after the nurse submitted the nursing plan patients, nurses ask things that can be helped, nurses come immediately when called patients and nurses look at patients to ask and check the patient's condition without being asked.

According to Egan (1998) in his book skilled helper one of the therapeutic communication indicators is responsiveness. ability Responsiveness (responsiveness), the attitude and behavior of hospital personnel to immediately serve when needed. If this is not done well, patients will feel less appreciated so that patients feel dissatisfaction, especially in terms of nurses' responsiveness in caring for patients[13,14,24].

Conclusion

Nurse communication model has been developed in the hospital by producing nurse communication modules in providing nursing care. The nurse communication model is influenced by nurse factors by mediating patient-nurse interactions.Nurse factors which include good perceptions, good judgment and good actions by nurses will increase interaction between nurses and patients Goodinteractions between nurses and patients will improve nurses' communication skills in providing nursing care.

Relationship between Satisfaction with Nurse Work Performance in Health Services in Hospitals

Suprapto

Nursing Academy of Sandi Karsa Makassar, South Sulawesi Indonesia

Abstract

Background: Of the current era of globalization suggests that market mechanisms will be increasingly dominated by business organizations that provide services or produce superior products that have good competitiveness and take advantage of market opportunities. Providing quality service is inseparable from human resources that produce good performance and achievement. One of the factors that correlates nurses' performance or work performance is the lack of a person's satisfaction with their work.

Method: Descriptive analytic research with cross sectional approach. Information and data in this study were collected through a questionnaire on all nurses who worked at the hospital. After the data is obtained then an analysis is carried out to find whether there is a relationship between job satisfaction and the work performance of implementing nurses.

Results: Show that nurses who have good job satisfaction are 15 people (57.7%), showing good job performance. This shows that nurses who have good job satisfaction will have the desire to provide more energy and responsibility in supporting the success and welfare of the hospital. Multivariate analysis shows that the independent variables are related to the dependent variable. The results of the analysis obtained job satisfaction of 0.50 then it can be stated to have a significant relationship to work performance.

Conclusion: There is a relationship between satisfaction with nurse work performance. There is a significant relationship between job satisfaction with work performance working in a hospital treatment room. In providing good and quality health services, both in terms of service, care and also good facilities for patients. Job satisfaction is proven to provide a relatively good relationship to the improvement of work performance, it also does not rule out the possibility for companies to consider other factors that can provide convenience in the field of health services.

Keywords: *Satisfaction, Achievement, Nurse.*

Introduction

The current era of globalization suggests that market mechanisms will be increasingly dominated by business organizations that provide services or produce superior products that have good competitiveness and take advantage of market opportunities. Providing quality service is inseparable from human resources that produce good performance and achievement. Job performance is something that is done or a product or service produced by a person or group, how the quality of work, accuracy and neatness of the work, assignments and fields of work, use and maintenance of equipment, initiative and creativity, discipline and work spirit (honesty, loyalty, a sense of oneness and responsibility and interpersonal relationships[4].

Employee performance appraisal is included in one of the activities of human resource development

(Human Resources Development) in every company organization, both in service industry organizations and in the manufacturing industry. Human resources, which are also a factor of production, are never free from appreciation, either because of their ability to do any work, or because of their work achievements in the form of promotion, promotion, salary increase, incentives and so forth. Giving awards, besides rewarding for an achievement, it is also a motivation for employees who have not performed well, so that in the future, their achievements can be improved[4].

Job satisfaction can be identified as an accumulation of the results of interactions that occur continuously between the person and the work and environment where he works in a certain period of time. Therefore, job characteristics and organizational climate are factors that are very closely related to job satisfaction and commitment and will ultimately have an impact on work performance or achievement[3].

Lack of individual factors (commitment, motivation and work ethic) and organizational factors (compensation, human resource development, leadership, supervision and working conditions) will relate to nurse performance as measured by measuring RATER (Reliability; Assurance, Tangible, Emphaty, Responsiveness) which is an indicator of nurse performance that will directly relate to hospital performance[11].

Job Satisfaction: The first person provides an understanding of the concept of job satisfaction. They assume that job satisfaction can be suspected from a person's attitude towards his job. Job satisfaction depends on what a person wants from his job and what is obtained. The people who are least satisfied are those who have the most desires, but get the least. While the most satisfied are people who want a lot and get it [2 7 9].

At the most basic mind, job satisfaction is a positive emotional state from evaluating one's work experience. Dissatisfaction arises when these expectations are not met. Job satisfaction has many dimensions. In general, the observed stages are satisfaction in the work itself, salary, recognition, the relationship between supervisors and workforce and opportunities for advancement. Each dimension produces feelings that are satisfied overall with the work itself, but work also has a different definition for others [6].

Work Performance: Job performance is also called performance or in English it is called performance. In principle, there is another term that better describes achievement in English, the word "achievement". But because the word comes from the word "to achieve" which means to achieve, then in Indonesian it is often interpreted as achievement or what is achieved ". Based on the understanding of work performance is the result of one's work, we need a system of measuring work performance or what is called work performance appraisal. Almost all ways of measuring work performance take into account quantity, quality and timeliness[5].

Job performance shows the work achieved by someone. said that work performance is a result of work achieved by a person in carrying out the tasks assigned to him based on skill, experience and earnestness of time. In other words that tangible work performance in a situation achieved by employees with better results increases than before [13].

Performance appraisals are carried out to obtain information that is useful in decision making related to other human resource management (HR) activities, such as planning and career development, compensation programs, promotions, transfers, pensions and dismissals. Performance appraisal in the context of the development of human resources is very important. This reminds us that in organizational life we want to get respect and fair treatment from the leaders of the organizations concerned. In the life of an organization there are several assumptions about human behavior as human resources that underlie the importance of assessing work performance [8].

Nurse: A nurse is someone who has completed a nursing education program both domestically and abroad that is recognized by the Government of the Republic of Indonesia, is registered and given the authority to carry out nursing practice in accordance with statutory regulations [10].

Nursing is one of the professions in hospitals that plays an important role in the implementation of efforts to maintain the quality of health services in hospitals. The standard on evaluation and quality control explains that nursing services guarantee high quality nursing care by continually engaging in quality control programs in hospitals. The role of nurses is very important because as the spearhead of good or not the quality of health services provided to patients. Nurses are one of the professions in the hospital with the most dominant

number and the longest contact or contact (interact) with patients in inpatient services for 24 hours [1].

Materials and Method

The research design is analytic descriptive research with cross sectional approach. Information and data in this study were collected through a questionnaire on nurses working in hospitals. Human resources, which are also a factor of production, are never free from appreciation, either because of their ability to do any work, or because of their work achievements in the form of promotion, promotion, salary increase, incentives and so forth. The awarding, besides rewarding for an achievement, is at the same time a motivation for employees who have not performed well, so that in the future, their achievements can be improved. Job satisfaction can be identified as the accumulation of the results of interactions that occur continuously between the person with the work and the environment in which he works in a certain period of time. Job characteristics and organizational climate are factors that are very closely related to job satisfaction and will ultimately have an impact on job performance or performance [12 14].

Findings:

Table 1. Analysis of the Relationship between Job Satisfaction and Work Achievement of Nurses in the Nursing Room

Job satisfaction	Work performance				Total	
	Well		Less			
	N	%	N	%	N	%
Well	5	38.5	1	3.8	6	42.3
Less	10	19.2	10	38.5	20	57.7
Total	15	57.7	11	42.3	26	100

$\alpha = 0,05$ $p= 0,003$

Table 2. Multivariate Analysis of Job Satisfaction with Work Performance of Implementing Nurses in the Treatment Room

		B	Exp(B)
Step 1[a]	Job satisfaction	-2.996	.050
	Constant	.693	2.000

Discussion

Distribution of respondents based on job satisfaction of nurses implementing in treatment room II shows the number of respondents 15 people (57.7%) who have good work performance. This shows that nurses have loyalty and feel attracted to the values, goals and objectives of the hospital where they work. The discovery of 5 people (19.2%) of respondents had less job satisfaction. This shows that nurses and hospitals lack the same goals, values and targets or nurses do not want to involve themselves more closely with hospitals. Based on the results of bivariate analysis, it showed that nurses who had good job satisfaction 15 people (57.7%), showed good work performance. This shows that nurses who have good job satisfaction will have the desire to provide more energy and responsibility, in supporting the success and welfare of the hospital.

Nurses who have good job satisfaction will have little reason to leave the hospital for a long time. This job satisfaction will have an impact on nurse performance, where the better job satisfaction is, the better work performance. This is evident through the willingness to work beyond what is expected so that the hospital can develop. Primary data shows that most nurses feel that working at the hospital is their best choice in making decisions about the workplace. The similarity

of values and goals between nurses and the hospital allows no difficulties experienced by the implementing nurse in every decision determined. from the hospital. Executing nurses who lack job satisfaction will have underachievement because the effort or the resulting performance is not optimal due to the lack of a sense of shared interest in the hospital[15 16].

Beta value is the value indicating the independent variable associated with the dependent variable. The results of the analysis obtained job satisfaction of 0.50 then it can be stated to have a significant relationship to work performance.

Conclusion

Based on the results of research on the relationship of job satisfaction with the work performance of implementing nurses in hospital treatment rooms; There is a relationship between job satisfaction and work performance of nurses in hospital treatment rooms. There is a significant relationship between nurse job satisfaction with work performance in hospital treatment rooms. In providing good and quality health services, both in terms of service, care and also good facilities for patients, the company must maintain employee work performance.

Flashcard Play Therapy for Pre-School Age on Reduction Stress Due Hospitalization

Syiddatul Budury[1], Diah Jerita Eka Sari[2], Widiharti[3], Andikawati Fitriasari[4]

[1]Faculty of Midwifery and Nursing of Nahdlatul Ulama University, Surabaya, [2]Nursing Department of Muhammadiyah University, Gresik, [3]Nursing Department of Muhammadiyah University, Gresik, [4]Faculty of Midwifery and Nursing of Nahdlatul Ulama University, Surabaya

Abstract

Stress due hospitalization of children is the main crisis situation actually founded in children that occurs because the child must stay at the hospital for some time, so that the child experiences stress due hospitalized. This study was conducted to evaluate the effect of giving flashcard therapy for the level of stress hospitalization at children of pre-school age. This is a pre-experimental analytical method with One Group Pre-Post Test design. The population were 40 children of pre-school period, aged 3-6 years, was conducted in children hospitalized at Syarifah Ambami Rato Ebu Hospital during April - May 2018. Data were analyzed using paired t test. Stress levels are measured using Holmes and Rahe's modified stress inventory scale. The results showed that stress levels due to hospitalization before and after giving flashcard play therapy had *P* value of 0,000 ($P<0.05$). So that it can be concluded that there was a significant differences in stress levels of hospitalization, it means that there was an effect of giving flashcard play therapy to reduce in stress levels at pre-school children due hospitalization. Flashcard play therapy can reduce the stress level of hospitalization in pre-school age children who are hospitalized.

Keywords: *Flashcard, Stress, Hospitalization, Preschool, Children.*

Introduction

During the children are hospitalized, it will make them feel threatened and stressed, this happens because the child is in an unfamiliar environment, also some medical procedures performed that can trigger fussy and angry children[1)]. Besides that, the different of new environments with their home cause anxiety and stress not only for children, but also for parents[2)]. Handling children who are stressed because they have to be hospitalized must be handled properly so as not to cause trauma. Nurses must be able to provide therapy that can relieve stressful conditions for children, one of which is playing therapy.

Playing becomes an important thing for children during hospital care[3)]. Playing can reduce the level of discomfort of children[4)]. Hospitalization will cause the child to experience trauma both short and long term[5)]. The child needs to be left to play so that the child can minimize the feeling of stress[6,7)]

Material and Method

This study was pre-experimental by using one group pre post-test, the childrens was measured the level of stress before being given flashcard play therapy and then measured again the stress level after playing flashcard therapy. The number of children was 40 children who were taken using simple random sampling and that were in accordance with the criteria of the study were children with a good level of consciousness, not in an isolated room and estimated length of stay in the hospital for about 4 days. This research was conducted after

obtaining parental consent. The treatment of the first session was carried out when the second day the child entered the hospital, which was measured first using the questionnaire stress level, then performed flashcard play (shown by figure 1), the child was told to guess the picture held by the nurse, the picture was shown little by little, after the picture was guessed the nurse would tell a short story related to the image, then repeat the same thing until it reaches at least 5 open flashcard. The activity was carried out approximately 15-20 minutes, the next day the play therapy was continued, for the second session it was the turn of the child who had to tell about the picture on the flashcard. And the third session just like second session. Then after the third session the level of hospitalization stress was measured again. After the data were collected, then it's processed using IMB SPSS version and the data were analyzed using paored t test.

Figure 1: The Flaschcard

Findings: The description of the child who became the object of the study consisted of 18 boys and 22 girls with different age levels (shown by table 1) the results of the paired t test showed Mean 6.90, Standard Deviation 3,002 and P Value 0,000 (shown by table 2). So that it can be concluded that there were a significant effect of playing flashcard therapy on reducing the level of stress at preschool due hospitalization.

Table 1. Participants demographics characteristics

No.	Variables	N	%
1	Gender		
	Boys	18	45
	Girls	22	55
2	Age		
	3 year old	10	25
	4 year old	10	25
	5 year old	11	27.5
	6 year old	9	22.5

Table 2. The Analysis of level stress

No.	Stress level	N	Mean	SD
1	Pre Test	40	27.8	6.8
2	Post Test	40	20.9	5.4
	Paired T Test		P Value 0.000	

The results of the study showed that before being given flashcard therapy for stress levels due to hospitalization was quite high, this was triggered because the pre-school age was vulnerable to stress and fear while at the hospital. According to Selye's definition of stress [8]. Stress is a non-specific response of the body to any excessive environmental request. The reaction to stress is not directly related to the exposure of stressors but is facilitated by the individual emotional response. Stress is, in fact, a process embracing several components including stressors, defined as events that pose a challenge to the subject, psychosocial mediators, constructs that enable the subject to evaluate the nature of the situation and the stress response, typically a measure of the emotional reaction elicited in response to the stressor [9]. Stress related to diseases and hospitals can have a long-term effect on the development of children [10]. It's means that the principle of atraumatic care is very important to apply in to the child ward. In pre-school period children stress can be derived from nursing interventions, pain, being left alone, lack of information and instruments and equipment, separation from parents[11].

Children usually have a very good relationship with their mother, as a result of separation from the mother will leave a sense of loss in the child so that in the end will cause feelings of insecurity and anxiety. As a result of being sick and being treated in a hospital, children will lose their freedom in developing their autonomy. Children will react negatively to the experience, especially children will become angry and aggressive.

Playing in a hospital for the child being treated has several functions, one of the most basic things is that play is a pleasant recreation [12]. Play therapy is a therapy that helps overcome anxiety and conflict. Playing releases tension, allows children to overcome life's problems. Play therapy allows children to channel excess energy and release emotions that are held back and cannot be released beforehand. In therapy, play also provides an opportunity to analyze children's conflicts and how to deal with them. In a therapy session, children can feel not threatened and more likely to express their true feelings. Therapy plays also as an effort to stimulate growth and development. play as a media part to express feelings of relaxation and distraction of uncomfortable feelings. Efforts to involve children in play activities will give a sense of responsibility to children, releasing them for a moment from the passive role as recipients of constant things everything has been done for them.

Flashcard games can add insight, practice introducing new vocabulary or new information and increase imagination. Flashcard games can also give distractions to children because this game can provide comfort so that children's stress can be reduced [13].

A Nurse's role in minimizing stress due to hospitalization in children is very important, so that nurses need to know several ways to cope with stress due to hospitalization in children one of which is the nursing care approach to playing flash cards. The role of nurses in implementing flashcards is as partners and facilitators in the care of children in hospitals. Because the activeness of nurses can be positive for children who are hospitalized, inactive children can become active even accustomed to being independent. Children who are given a nursing care approach to play flashcard are involved in the process of independence of children such as children choosing to eat on their own, children managing their own sleep time. While parents accompany children 24 hours, parents also get an explanation of hospital policies, procedures and regulations.

Most children expressed happiness and joy after being given the approach to playing flascard because according to children the presence of parents in addition to children is needed by children and can improve the relationship between children and their parents. The reaction of parents to hospitalization such as feelings of fear, anxiety, guilt and sadness also greatly affects the child during treatment. Where if parents are stressed during child care, the child's stress level will increase

as well, so that while the child is undergoing treatment in the hospital the role and support of parents is very helpful in reducing the stress level of hospitalization in children [14].

Conclusion

Playing flashcard at preschool due hospitalization can reduce stress levels. Nurses and parent must be proactive to give children therapy, especially with flashcard.

Conflict of Interest: All the authors of the study expressly state no conflict of interest to be considered.

Pharmacological Activities and Chemical Constituents of Bryoniadioica L.: A Review

Thamer Mouhi Jasiem[1], Rasha Eldalawy[1], Zahraa Abdul Elah Alnaqqash[1]

[1]*Department of Pharmacognosy and Medicinal Plant, College of Pharmacy, Mustansiriyah University, Iraq*

Abstract

Bryonia is one of the genera belong the Cucurbitaceae family (gourd family). *Bryoniadioica* distribute in Western Europe, this plant flowering in May as small, greenish and three or four flowers together in small cluster the stamens and pistils are found separated therefore consider a dioecious plant–growth as separate plant into (male and female).The phytochemical constituents of Leavesare Luteolin, flavonoids (kaempferol),. alkaloids, Glycosides, phenol steroids,, Carbohydrates, anthraquinoine and terpenoids, while the part used of this plant (Roots) are Kempferol 3, 7-di-O-rhamnoside, polyphenols, sterols, triterpenes, alkaloids, heterosides-c, carbohydrates, saponins, terpenoids, flavonoids, tannins, alkaloids, quinones, reducing sugar and coumarin . The fruits containing triterpene, glucosides, calcium oxalate crystals and the flowers arePhenolic acid and flavonoids. The biological activity and pharmacological uses of all plant parts of *B.dioica* are antinociceptive effects, antimicrobial activities, antioxidant activity, hepatoprotective activity, Anticancer activity, hypercholesterolemia, diabetes and fertility disorders .

Keywords: *Bryoniadioica, phytochemical constituents, biological activity and pharmacological uses.*

Introduction

Bryonia is one of the genera belong the Cucurbitaceae family (gourd family) which is flowering plant[1,2]. The genus name Bryonia, came from the bryo word (Greek bryo), which means shoot, or appears of sprout according to the active growth of the plant stems[3]. The best-known common name is Bryony[4,5]. *B. dioica* distributed in Western Europe[6-8]. It has five-pointed leaves with different flowers like blue or white[9]. This plant flowering in May as small, greenish and three or four flowers together in small cluster the stamens and pistils are found separated therefore *B.dioica* consider a dioecious plant – growth as separate plant into (male and female) flowers with many petals (five greenish-white petals)[10]. Male flowers about 12 to 18 mm and having stalked bunches and loose. The stamens consist of one-celled and the anthers are yellow, while the female flowers about 10 to 12mm[11,12]. The fertile flowers, distinguish easily by the presence of an ovary beneath the calyx, in general without stalk (sessile) about two to five fertile flowers together. when the stem and leaves are withered, The berries, hang about the bushes, about peas size when ripe, take pale scarlet color containing six seeds in large size and filly juice[13]. The stems of *B.dioica* plant containing a long tendrils, which use for climb and its springing from the stalks of leaves and the tendrils between the shrubs and trees extend for many yards during the summer season and when the fruit is ripening the tendrils drying as vine shaped very rough with leaves and form like prick-hairs and its consider as general character for this plant[14-16]. The leaf blade is lobed, which is divided into five lobes and the middle one is longer than others, in general the leaves consider as curved stalked shape[17]. The part used of this plant is the root which collected in the autumn and used as fresh and dry state[18]. The fresh root take a dirty yellow or yellowish-white, when cutting the root obtain milky juice as a bitter and acrid taste. . The root is simple, like a carrot and some time forked into two parts.[19-20]

The medicinal uses of *B. dioica* plant for Irritative, hydragogue and cathartic. But now don't recommended used as a purgative because its cause discomfortable and irritation [21-23]. It is useful in different diseases but in small doses used in cough, influenza, bronchitis, pneumonia, pleurisy and whooping-cough . Also used for cardiac disorders caused by rheumatism and gout, also in malarial and zymotic diseases [24] .

Vernacular Names: There are many common names for *B.dioica* plant like white bryony, mandrake, ladies' seal, Tetterbury, red bryony, Wild Vine, Wild Hops, Wild Nep. Tamus and in French Navet du diable[25-28].

Scientific Classification	
Kingdom:	Plantae
Clade:	Angiosperms
Order:	Cucurbitales
Family:	Cucurbitaceae
Subfamily:	Cucurbitoideae
Genus:	Bryonia
Species	Bryoniadioica L.

Figure (1) leaves and fruits of Bryoniadioica L. plant

Table (1) Phytochemistry review

Plant Part	**Constituent Reported**
Leaves	Luteolin, flavonoids (kaempferol)[29-31]. alkaloids, Glycosides, phenol steroids,, Carbohydrates and, anthraquinoine and terpenoids [32-35].
Flowers	Phenolic acid, flavonoids [36].
Fruit	Triterpeneglucosides and calcium oxalate crystals [37].
Root	Kempferol3, 7-di-O-rhamnoside[38], polyphenols, sterols, triterpenes, alkaloids [39], heterosides-c, carbohydrates, saponins, terpenoids, flavonoids, tannins, alkaloids,quinones, reducing sugar, coumarin [40-43].

Pharmacological and Biological Activities:

1. Antinociceptive Effects:

The antinociceptive activity of the leaves extract of Bryoniadioica plant confirm by hydroalcoholic extract of leaves by used standard test of tail flick and formalin which is one of the most common test used for measured the antinociceptive activity with acetic acid used as chemical stimulationthe results were observed that dose of 300 mg/kg with $P < 0.01$[44]. and the compared between the leaves extract and indomethacin shown that no significant difference between them at dose of 300 mg/kg of leaves extract and the results determined the LD50 of the plant extract was 4200 mg/kg[45].

2. **Antimicrobial activities:** The leaves extract of Bryoniadioica plant has a referred to antibacterial activity against many of pathogenic bacteria such as E.coli, K. pneumoniea and P. valgaris. the results significant that activity against gram negative bacteria.The maximum inhibition zone (MIC)was 227.3mg ml-1 against P. valgariswhile 186 mg ml-1 against K.pneumoniea and then against E.coli was 143.9 mg ml-1[46,47].

3. **Antioxidant activity:** The phenols and flavonoids in the B.dioica plant act as antioxidant activities those active compounds found in different parts of this plant (leaves, stem and flower) and those active compounds act as radical scavenging capacity, the flowers of B.dioica consider an important part used rich in phytochemical compounds and act as antioxidant this study done by measured the scavenging activity by colorimetric assay DPPH and presented by IC50 value, the polar stem extract concentration at 28.75 µg/ml shown highest radical scavenging activity and in non polar extract at 31.27 µg/ml, while in leaves extract were 76.08 µg/ml in polar and 83.62 µg/ml in non polar and finally in flower extract were 98.35µg/ml in polar and 91.54 µg/ml in non polar [48,49].

4. **Hepatoprotective activity:** The hepatoprotective action of leaves extract of B.dioica plant was investigated by used oral dose about 250mg/kg plant leaves extract for week this study was used Rats model by histopathological effect in Rats liver which induce hepatotoxicity by used $CCl_4$and investigated the hepatoprotective activity of this extract in serum tested as the biochemical marker for hepatotoxicity AST and ALT . The leaves extract shown decrease the enzymes level by decrease the CCL_4 cause the plant extract have very important constituents like flavonoids, alkaloids, terpenoids, sterols [50].

5. **Anticancer activity:** In Algerian study which proved the local population used the extract of B. dioica roots for treatment of breast cancer used this root extract only or by mixed this extract with honey and this study reported treat cancer 26% this study attributed to presence the major active compound :Kempferol 3, 7-di-O-rhamnoside which induced cell death in cancer cell line and also the same study reported the root extract treat hypercholesterolemia (22%), diabetes (18%), fertility disorders (14%)[51].

Conclusion

B. dioicaone of the medicinal plant which widely used in traditional medicine and distribution in different countries specially in Western Europe and containing many active ingredients in all types of plant specially in root which consider as part used in this plant such as Kempferol 3, 7-di-O-rhamnoside and polyphenols which responsible for many biological activity and pharmacological uses such as antinociceptive effects, antioxidant activity, hepatoprotective activity, Anticancer activity, hypercholesterolemia, diabetes and fertility disorders .

Group-Based Education Program on Self-Care toward Reduction of Diabetic Foot Risk on Type-2 Diabetes Mellitus Patients

Tini Tini[1], Laili Rahayuwati[2], Ahmad Yamin[2]

[1]Poltekkes Kemenkes Kaltim, [2]Faculty of Nursing, Universitas Padjadjaran, Indonesia

Abstract

Diabetes mellitus patients are at risk of 15% having diabetic foot complications during their lifetime and 70% recurrence within 5 years. Studies show that educational programs can help improve self-care and reduce the risk of diabetic foot. Educational approach that is considered effective and efficient is education in groups. This study aims to determine the effect of group-based educational programs on self-care towards diabetic foot risk score in patients with type 2 diabetes mellitus. Design of quasi experiment research utilized the pre-test and post-test with control group. The intervention and control group was determined through cluster sampling on Garuda Central Healthcare Public area in Bandung City. Respondents were taken by purposive sampling as much as 68 respondents, which is intervention group (n = 33) and control group (n = 35). Data were collected using self-care questionnaires and diabetic foot risk screening. Data were analyzed by paired t test and independent t test. The result showed that there was difference of diabetic foot risk score between groups (p value 0.001). Self-care activities were also found to differ in the intervention group (p value 0.000) and control group (p value 0.001). Group-based education programs on self-care have an effect on decreasing the risk of diabetic foot. This program can be applied in public health care activities (*Perkesmas*) by improving self-care monitoring and diabetic foot risk in patients with diabetes mellitus.

Keyword: *Diabetes mellitus, group-based education, self-care, diabetic foot risk.*

Introduction

Diabetes mellitus is one of chronic diseases with increasing numbers of patients throughout the globe. The International Diabetes Federation proclaims in 2015 that 415 million adults worldwide were diagnosed with diabetes mellitus and this number will go up to 642 million in 2040[1]. Indonesia places the 7th in the world for the highest diabetes prevalence after China, India, America, Brazil, Russia and Mexico[1]. Based on the *Riskesdas* (Basic Health Research) (2013) West Java, an increase occurs from 1.4% prevalence in 2007 to 2% in 2013, along with the highest number of people (225.000) with diabetes mellitus but were left unchecked[2].

Public Health Centre (*Puskesmas*) Garuda is one of the community health centers with the highest number of diabetes mellitus patients in Bandung. This disease places the 10 most suffered disease and the highest number of deaths in Case Fatality Rate (CFR) (5.7%). The disobedience of diabetes mellitus patients in performing self-care could both worsen their conditions and trigger more complications[4]. One of the chronic complications occurs on their foot, or more commonly known as diabetic foot. It is a set of wounds on foot related to neuropathic damages and bloodstream disorder due to high glucose level[3]. Type-2 diabetes mellitus patients have a 15% risk of diabetic foot ulcer in their life and 70% risk of recurrence in 5 years[5].

The International Working Group on the Diabetic Foot claimed that 1 of 6 diabetes mellitus patients died due to this and each year 4 million people in the world are diagnosed with foot ulcer which can lead to amputation[6]. Foot screening check has come to be necessary to identify the foot risk condition[7]. A research by Reid et.al (2006) found that 82% of diabetes mellitus patients have the average of 3 foot problems for each individual[8]. Besides, Leese et.al (2006) claimed that high-risk patients have

86 times higher chances to suffer from foot ulcer while the moderate-risk ones have 6 times[9]. On the other hand, those who are in a low-risk group show 99.7% chance exempt from wounds for 2.5 years .

Previous study found that there is a relation between the patient's obedience in diet patterns, glucose level control, activity and foot treatment with diabetic ulcer phenomenon (p value = 0.000)[10]. In contrast, the disobedient patients have a 34 time higher chance to suffer from diabetic ulcer. Therefore, it is required that any prevention effort be done to reduce the risk of diabetic foot through independent self-care effort promotion[11].

A research by Kafaiae et.al (2012) found that education programs are impactful in the improvement of foot lesion (84%) and nails (62.8%)[12]. This corresponds to the result of systematic study that the health education program by foot checking, verbal and written instructions as well as discussions, prove effective in healing independent foot treatment and other pediatric problems such as neuropathy, disability, lesion, ulcer, *tineapedis* and callus[13].

The approaches used in various educational vary widely individually, group or family. Individual education requires more space and time for health workers to examine more in the patients specific needs, so this is seen as less effective and efficient[14]. Previous study found that educational interventions involving family can increase the knowledge, efficacy and behavior of patients in performing foot care (p value 0.000)[15]. But involving the family in the education process needs to pay attention to culture and family type.

Group-based education programs are an interactively designed and cost-effective strategy, through which the members of the group are allowed to discuss, communicate and exchange experiences in solving problems. Besides, each member of the group can actively participate during the process[16]. This research aims at identifying the impact of group-based education program about self-care on the risk of diabetic foot for type-2 diabetes mellitus patients in Public Health Centre of Garuda Bandung.

Material and Method

The design used in this research was that of "quasi experiment" with pre-post test with control group. The determination of intervention and control group used cluster sampling technique in Public Health Centre of Garuda Bandung. On the other hand, the respondents in each urban village were taken using purposive sampling technique. Through the numeric analytical research samples, along with Z_β 0.84; SD 1.8 and 0.9 minimum margin and 20% drop-out estimation, 37 respondents on each group were finally selected.

The variable in this research includes group-based education program and the risk of diabetic foot. The instrument used is Inlow's Screening Tools 60-Second Diabetic Foot from Canadian Association of Wound Care, as many as 5 indicators. On the other hand, the activity of self-care is measured using the Summary of Diabetes Mellitus Self Care Activities instrument[17].

The validity and reliability of Inlow's 60-second Diabetic Foot Screening Tool instrument have been tested by Murphy et.al (2012)[18]. Using *Kappa* test, the analysis result has found no different perception between tester 1 and 2 to the observed aspect (p value 0.000). For SDSCA instrument, it is obtained that r measured > r table (0.361) and the result of reliability analysis using *alpha Cronbach* is 0.76. Both results show that the instruments are valid and reliable[19]. The analysis done in this research included *t paired* and *independent test* with the trust score of 95% on the self-care scores and diabetic foot risks.

This research was done in hamlets by making educational groups consisting of 5 to 7 people each. Before intervention, each respondent is given questionnaires to be filled and screening for diabetic foot risk by 2 testers. The group-based educational intervention consists of 4 sessions each week (1 session/week). This educational program was conducted in 2 sessions for 60-90 minutes each through lectures and demonstration and using AVA and modules as the media.

At the end of each education activity, respondents are asked to set goal setting as follow up plan at home and record their self care activities on self report sheet each day. In the 3rd and 4th sessions in the interference group, sharing and discussion were also done by exchanging experiences, identifying the problems and looking for solution together. On the fifth week, an evaluation was done on self-care and diabetic foot for both groups.

Findings: From 74 chosen respondents, six of whom were not present during the research activity. Therefore, 68 respondents in total were divided into 33 people were in the intervention group and 35 in control group.

Table 1 shows the average age of intervention group of 61.85 and control group of 59.4. The majority of respondents are women in the intervention group (81.8%) and group control (82.9%). The education level are elementary school graduates in the intervention group (60.6%) and control (48.6%). Most of the respondents have suffered from diabetes mellitus for 1 – 5 years in the intervention group (48.5%) and control (45.7%). Based on the result of homogeneity test, it is obtained that all data from both groups are not significantly different in terms of statistics (p>0.05).

Table 1: Frequency Distribution of Respondents Characteristics and Result of Homogeneity Test on Intervention and Control Group (N=68)

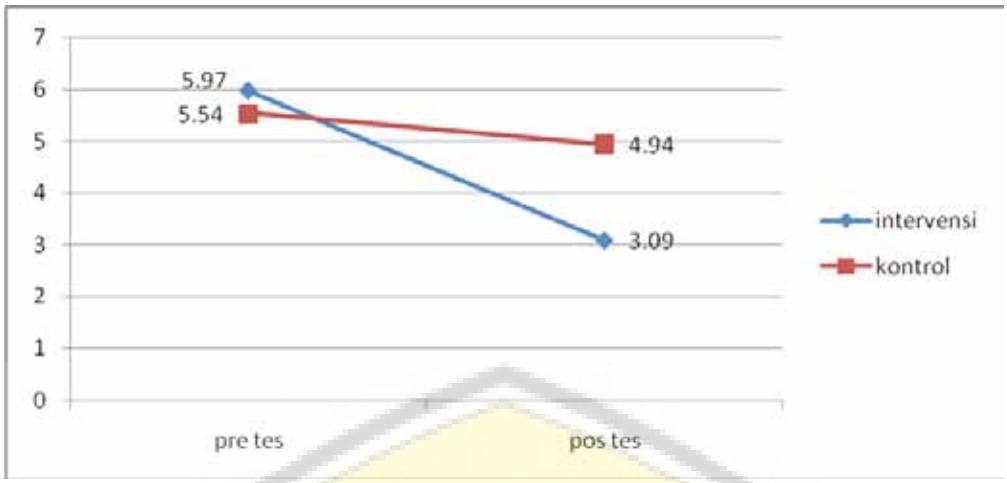
Characteristics	Intervention Group (n=33)		Control Group (n=35)		p value
	f	%	f	%	
Age	Mean 61.85 Min-Max 50-80		Mean 59.40 Min-Max 38-74		0.48a
Gender					
Male	6	18.2	6	17.1	0.56b
Female	27	81.8	29	82.9	
Education					
Elementary School	20	60.6	17	48.6	
Middle School	8	24.2	6	17.1	0.56c
High School	5	15.2	10	28.6	
University	0	0	2	5.7	
Sickness Period					
< 1 year	4	12.1	2	5.7	
1-5 year	16	48.5	16	45.7	0.99c
6-10 year	4	12.1	6	17.1	
> 10 year	9	27.3	11	31.4	

Homogeneity Test: a=Independent Test, b=*Fisher Exact*, c=*Kolomogorov Smirnov*

Table 2. Indicator Value Comparison of Pre-Test and Post-Test Self-Care Activity on Intervention and Control Group (N=68).

Activity Self-Care	Intervention Group (n=33)		Control Group (n=35)	
	Pre Test	Post Test	Pre Test	Post Test
	Mean	Mean	Mean	Mean
Eating Pattern	3.29	5.34	3.40	4.39
Physical Activity	2.59	5.26	2.19	2.47
Glucose Control	0.45	0.85	0.31	1.01
Treatment	5.52	6.21	5.80	6.09
Foot Care	1.36	5.62	0.84	1.61

Based on Table 2, we could see the average margin of eating activity from pre-test to post-test is 2.05, bigger than the control group, 0.99. In terms of physical activity, the average margin reaches 2.67 on the intervention and 0.28 on the control group. This corresponds to the foot care aspect, a significant increase occurs in the intervention group with average margin 4.26 and 0.77 in the control. Meanwhile, in terms of treatment and glucose control, a relatively similar increase applies on both groups.



Graphic 1. Score Distribution of Diabetic Foot Risk during Pre-Test and Post-Test in the Intervention and Control Group (N=68).

Based on Graphic 1, we could see that the average value for diabetic foot risk in the intervention (5.97) and control group (5.54) are relatively similar. A nosedive occurs to the average score of diabetic foot risk in the intervention group (2.88), while in control, the margin is only 0.6.

Table 3: Analysis of Average Score Difference of Diabetic Foot Risk during Pre-Test and Post-Test on the Intervention and Control Group.

Score of Diabetic Foot Risk		Pre Test (P1)	Post Test (P2)	Difference (P3)	Test	
		Mean±SD	Mean±SD	Mean±SD	t	P
Intervention Group		5.97±1.53	3.09±1.86	2.88±1.71	9.67 [a]	0.001
Control Group		5.54±1.80	4.94±2.32	0.6±1.66	2.13[a]	0.040
Uji	t	1.049[b]	3.61[b]	5.56[b]		
	P	0.290	0.001	0.001		

df (intervention)=32, df (control)=34, a=*Paired t test*, b= *Independent t Test*

Based on Table 3, the result of statistics *Independent t test* shows significant difference occurs on both group with p value 0.001. This result responds to the hypothesis saying that the impact of group-based education program exists on the average score of diabetic foot risk.

Discussion

In this research found that the group-based education program on self-care has given impacts on the decline of score for diabetic foot risk for type-2 diabetes mellitus patients in Public Health Centre of Garuda Bandung (p value 0.001). Although each group has score decline of diabetic foot risk with p value < 0.05, the decline is bigger on the group that has undergone the program, with 2.88±1.71 margin. In contrast, the control group remains on 0.6±1.66 margin. However, these facts correspond to previous researches showed that education can reduce the risk of diabetic ulcer (p value < 0.001)[11].

Diabetes mellitus patients, entail the risk to suffer from complications of diabetic foot during his life. However, this can be prevented by providing proper education[20]. This is done because education can change their behavior in undergoing independent treatment of diabetes mellitus. Supplying information for patients might be a stimulus that can improve their knowledge and raise their awareness to behave as expected. The

practice of good self-care has had relation with the glucose control and its prevention from complication, one of which is diabetic foot[21].

The group-based education program is part of the interventional strategy of the communal nurses. It aims at providing knowledge and skill, identifying setbacks and facilitating problem-solving process. This is more effective and more powerful to ensure behavioral changes for each individual[22]. Communal approaches offer forum for diabetic patients to gather and learn. Furthermore, it can also provide a conducive learning environment and create a supportive atmosphere.

The increase of the average self-care activities in the intervention and control group is in line with the decline of the average score of diabetic foot risk for both groups. The program in fact can improve the patient's knowledge and skills for independent self-care. Although insignificant, a decrease occurs on the average score of diabetic foot risk in the control group. This is because they need to submit a report every week. The self-report was not only useful to see the patient's weekly progress on the self-care activities. It could also be a grip and reminder for respondents to do the cycle in case they were off-track[16]. None the less, in the control group, the self-report was not evaluated weekly, hence the self-care activity tended to remain stagnant and progress lesser than the one on the intervention group.

Conclusion

Providing the small-group-based education program, modules, sharing and discussion, goal setting as well as good self-care monitoring and frequent foot screening, may affect the level of diabetic foot risk. Furthermore, the result of research also shows an increase of average total score on self-care activity including eating pattern, physical activity, treatment, glucose control and foot care for both groups.

Conflict of Interest Statement: The authors of this research declare that there is no conflict of interest related to this study.

Source of Funding: All funds used to support this research comes from the researchers themselves and Faculty of Nursing Universitas Padjadjaran.

Ethical Clearance: This research has obtained ethical permission from the Committee of Ethics of Research Unit Faculty of Medicine in the Teaching Hospital Universitas Padjadjaran, Eijkman College Bandung with number "462/UN6.C10/PN/2017".

Risk Factors for Neonatal Asphyxia Occurrence at General Hospital Dr. M. Soewandhie, Surabaya

Tri Adharia Sekarwati[1], Ninik Darsini[2], Dominicus Husada[3]

[1]Midwifery Programme, [2]Biomedical Department, [3]Department of Child Health, Faculty of Medicine, Universitas Airlangga, Surabaya

Abstract

Background: Neonatal mortality rates in Indonesia are still high at 15 per 1000 live births. Surabaya is one of the regions with the highest number of neonatal deaths in East Java. Neonatal asphyxia is the highest cause of neonatal death after preterm birth. Some factors that cause neonatal asphyxia include maternal factors, labor and fetal factors. This study aims to identify the risk factors that influence the incidence of neonatal asphyxia.

Method: This medical-based study using a case-control approach used neonatal medical record data that was born in the period of January 1, 2018, to December 31, 2018, in the General Hospital of dr. M. Soewandhie, Surabaya. Samples were selected based on inclusion and exclusion criteria. Sampling was done by total sampling in the case group (93 neonates) and simple random sampling in the control group (93 neonates) and matching was done based on sex and birth month. Data analysis was performed by univariate, chi-square and fisher's exact test and multivariate with multiple logistic regression.

Results: Neonates with diagnosed neonatal asphyxia were born to mothers who had low education (63.4%) and did not work (68.8%). Risk factors that significantly increased the incidence of neonatal asphyxia were: non-spontaneous labor with OR=5.56 (95%CI: 2.50-12.34), preeclampsia with OR=2.52 (95%CI: 1.15-5.54), meconium-stained amniotic fluid with OR=2.51 (95%CI: 1.17-5.38) and primiparous parity with OR=2.15 (95%CI: 1.06-4.39).

Conclusion: Non-spontaneous labor, preeclampsia, *meconium*-stained *amniotic fluid* and primiparous parity affect the incidence of neonatal asphyxia.

Keywords: *Neonatal asphyxia, non-spontaneous labor, preeclampsia, meconium-stained amniotic fluid, primiparous.*

Introduction

The number of child deaths under five years is as many as 5.4 million children with an under-five mortality rate of 39 per 1,000 live births, as much as 47% of these deaths occur in neonatal, which is 18 per 1,000 live births[1]. The neonatal mortality rate in Indonesia is 15 per 1000 live births. This figure is still quite far from the Sustainable Development Goals (SDGs) target, which is to reduce neonatal mortality to a minimum of 12 per 1,000 live births[2]. Neonatal mortality rates in East Java experienced an insignificant decrease from 2015 to 2017[3] with neonatal asphyxia as the highest cause of neonatal death after preterm birth[4].

Neonatal asphyxia is a result of intrapartum hypoxia/ischemia of the fetus and resuscitation measures which

Corresponding Author:

Phone: +62818337734
e-mail: dominicushusada@yahoo.com

can immediately restore the condition of the newborn[5]. This condition results in malfunctioning of vital organs, brain damage to death[6]. Causes of neonatal asphyxia include hypertension in pregnancy, post-term pregnancy, maternal narcotics during labor, uterine contractions (hypertonic or tetania uterine), disorders of the umbilical cord and hypovolemic shock[7]. Risk factors for neonatal asphyxia include maternal age, maternal education, parity, anemia during pregnancy, prolonged labor, premature rupture of membranes, low birth weight[8] and very low birth weight in neonates[9]. Preeclampsia in pregnancy can increase the risk of neonatal asphyxia[10]. Obesity in pregnant women also increases the incidence of severe asphyxia in neonates[11].

This study aims to identify risk factors for the incidence of neonatal asphyxia so that it is expected to be prevented and reduced.

Material and Method

This was medical-based research with a case-control approach. The population in this study were neonates born at the General Hospital of dr. M. Soewandhie, Surabaya in the period January 1, to December 31, 2018, obtained from medical records. The inclusion criteria for case samples were neonates born with neonatal asphyxia diagnoses and had complete medical record data and could be read by the author. The inclusion criteria for the control sample were neonates who were born without neonatal asphyxia and had complete medical record data and could be read by the author. The exclusion criteria in this study were neonates born with congenital abnormalities such as congenital heart defects and diaphragmatic hernias. The sampling technique was total sampling in the case group and simple random sampling in the control group and matching was done based on sex and birth month. Samples obtained were 186 neonates divided into 93 cases and 93 controls. The variables in the study consisted of the dependent variables namely neonatal asphyxia and independent variables namely parity, maternal age, prematurity, birth weight, obesity, anemia during pregnancy, preeclampsia, type of labor, premature rupture of membranes (PROM), prolonged labor and *meconium*-stained *amniotic* fluid (MSAF). Data were analyzed by univariate, Chi-Square and Fisher's Exact Test and multivariate (Backward Stepwise: Likelihood Ratio) using a statistical program (SPSS version 16).

General Hospital of dr. M. Soewandhie, Surabaya was one of the largest secondary hospitals in Surabaya. This hospital had 356 patient beds with as many patients (inpatient = 26,590, outpatient = 275,628) per year. There were 104 medical personnel and 527 paramedics.

Results

The percentage of neonatal asphyxia births was 4.4% (142/3,267). The total sample of cases was 142, as many as 93 samples stated included inclusion criteria. Case and control samples were matched based on sex and birth month of newborns. Table 1 showed that the sex in each case and control group were 52 samples (55.9%) for male and 41 samples (44.1%) for female.

Table 1: Comparability by sex in the case and control groups

Sex of newborns	Neonates	
	Cases n = 93 (%)	Controls n = 93 (%)
Male	52 (55,9%)	52 (55,9%)
Female	41 (44,1%)	41 (44,1%)

Table 2 showed that as many as 59 (63.4%) case samples and 55 (59.1%) control samples were born to mothers with low education. A total of 64 (68.8%) case samples and 57 (61.3%) control samples were born to mothers who did not work.

Table 2: Characteristics of mothers based on education and occupation in cases and controls

Characteristics	Neonates	
	Cases n = 93 (%)	Controls n = 93 (%)
Education		
Low (primary school/middle school)	59 (63,4%)	55 (59,1%)
High (high school/diploma/ bachelor)	34 (36,6%)	38 (40,9%)
Occupation		
Not working (housewife)	64 (68,8%)	57 (61,3%)
Working	29 (31,2%)	36 (38,7%)

Table 3 showed the results on each of the independent variables that are significantly related to neonatal asphyxia were parity, obesity, preeclampsia, type of labor, prolonged labor and MSAF. The highest crude odds ratio was found in non-spontaneous labor, which was 3.71 (95% CI: 1.81-7.64). As for the variables of maternal age, prematurity, birth weight, anemia and PROM were not related (p-value > α) with the incidence of neonatal asphyxia.

Table 3 the relationship of risk factors for the incidence of neonatal asphyxia

Variables	Neonates		Crude OR	95% CI	P-value*
	Cases n = 93 (%)	Controls n = 93 (%)

*Chi Square/Fisher's Exact Test

Table 4 showed the results of multivariate analysis with the Backward Stepwise method in order to obtain the final model of multiple logistic regression. Variables with p values <0.25 in the Chi-Square/Fisher's Exact Test were included in the multivariate analysis, which included eight variables. Parity, preeclampsia, type of labor and MSAF were risk factors for neonatal asphyxia.

The analysis showed that the type of labor with non-spontaneous (CS/VE/manual aid) had a risk of 5.6 times to deliver babies with neonatal asphyxia (OR = 5.56; 95% CI: 2.50-12.34) compared to spontaneous labor. The risk of neonatal asphyxia in women with preeclampsia was 2.5 times higher than in women without preeclampsia (OR = 2.52; 95% CI: 1.15-5.54).

Similar to preeclampsia, MSAF also had a 2.5-fold risk of increasing the incidence of neonatal asphyxia (OR = 2.51; 95% CI: 1.17-5.38). Compared to multiparous mothers, mothers with primiparous parity had a 2.1 risk of giving birth to infants with neonatal asphyxia (OR = 2.15; 95% CI: 1.06-4.39).

Table 4: Results of multivariate regression

Variables	B	P-value	Odds Ratio	95.0% C.I. for OR	
				Lower	Upper
Parity (1)	0,767	0,035	2,152	1,055	4,392
Preeclampsia (1)	0,924	0,022	2,519	1,146	5,540
Type of labor (1)	1,715	< 0,001	5,555	2,500	12,343
Prolonged labor (1)	20,970	0,999	1,280E9	< 0,001	.
MSAF (1)	0,919	0,018	2,507	1,170	5,376
Constant	-1,223	< 0,001	0,294		

Discussion

This study aimed to identify risk factors for neonatal asphyxia, which was by including several determinants that might be risk factors for neonatal asphyxia. Therefore, neonatal asphyxia could be prevented and inherited.

This study showed that neonatal asphyxia mostly occurred in male neonates. This study was in accordance with a study in the United States, which states that 56.2% of neonates with neonatal asphyxia were male. There was no clear theory yet, but this might be related to male vulnerability (XY chromosome) to cerebral anoxia compared to women because there was an additional X chromosome[12].

Maternal characteristics showed that the majority of neonatal asphyxia incidents were born to mothers with low education and no work. This result was in line with a study conducted in Jakarta[13], neonates with neonatal asphyxia were born to mothers with low education (90.6%) and from mothers who did not work by 77.8%. In Northern Ethiopia, the majority of neonatal asphyxia were born to mothers with low education (84.1%) and from mothers who did not work (housewives) by 53.4%[6].

Parity had a significant relationship with the incidence of neonatal asphyxia. Mothers with primiparous parity had a 2.2 times higher risk of giving birth to babies with neonatal asphyxia (OR = 2.15; 95% CI: 1.06-4.39) compared to multiparous mothers. The results of this study differed from studies conducted in Ethiopia, which showed that parity did not affect the incidence of asphyxia[14]. However, another study showed that primiparous mothers had 3.1 times higher risk of giving birth to babies with neonatal asphyxia. This might be related to primiparous mothers who often did not know their pregnancy needs and even ignored antenatal care visits[6]. In the first pregnancy, cervical muscles tended to be stiff so that labor took a long time, which could increase the risk of neonatal asphyxia[15].

Mothers with preeclampsia during pregnancy had 2.5 times the risk of giving birth to neonatal asphyxia babies (OR = 2.52; 95% CI: 1.15-5.54) compared to women who did not experience preeclampsia during pregnancy. This was in line with a study conducted in Ethiopia[6], [14], which showed that preeclampsia increases the risk of the incidence of neonatal asphyxia by 4.1 times and 2.6 times, respectively. The result might be related to changes in the cardiovascular system due to an increase in blood pressure and vascular spasm[10], resulting in placental insufficiency and fetal hypoxia[16].

The type of delivery had a significant relationship with the incidence of neonatal asphyxia. Labor with non-spontaneous (CS/VE/manual aid) had a 5.6 times higher risk of delivering a baby with neonatal asphyxia (OR = 5.56; 95% CI: 2.50-12.34) compared to spontaneous labor. These results were not consistent with a study conducted in Bali[8] but were consistent with studies in Ethiopia which stated that labor with cesarean section had a 7-fold risk of increasing the risk of neonatal asphyxia[14]. This was related to impaired perfusion and vascular resistance due to anesthesia during the

cesarean section and this action also resulted in no chest compressions in infants such as in vaginal delivery[17]. In addition, the used of medical devices such as forceps and or a vacuum extractor during labor could result in trauma and intracranial hemorrhage, which hindered the baby's circulation[16].

Meconium-stained *amniotic* fluid at delivery have a 2.5 times higher risk for neonatal asphyxia in infants (OR = 2.51; 95% CI: 1.17-5.38) compared with clear membranes. These results were consistent with studies in Ethiopia[14], which showed that MSAF had a risk of 8.6 times to occurred neonatal asphyxia. The presence of MSAF at delivery indicated that fetal distress had occurred[18]. This results in meconium aspiration syndrome, which resulted in the obstruction of the baby's respiratory tract[15].

The limitation of this study was that it used secondary data, namely medical record data, so that much of the information needed was not available. In addition, this study was only conducted in one hospital in the city of Surabaya, so the study could not be generalized to a wider population.

Conclusion

Non-spontaneous labor, preeclampsia, primiparous and MSAF are risk factors for neonatal asphyxia. Midwives as a companion for pregnant women and maternity mothers are expected to improve the quality of education and early detection of risk factors. In addition, midwives are expected to be able to carry out close monitoring during labor and identify any complications during labor. Having the right diagnosis and treatment can improve the quality of fetal output.

It is expected that further authors will conduct a more specific study on the incidence of neonatal asphyxia with the factors that influence it. In addition, it is hoped that the community can increase awareness in recognizing high risks in pregnancy and childbirth so that it can reduce morbidity and mortality rates for mothers and infants.

Conflict of Interest: This study was conducted without conflict of interest from person or organization or commercial interests such as financial relationship, personal relationship, academic competition or intellectual passion.

Source of Funding: Self-funding.

Ethical Clearance: This study has obtained an ethical clearance certificate from the Health Research Ethics Committee, Faculty of Medicine, Airlangga University, Surabaya No. 96/EC/KEPK/FKUA/2019, obtained on April 8, 2019 and from the Medical Research Ethics Committee of General Hospital of Dr. M Soewandhie, Surabaya No. 006/KE/KEPK/2019, obtained on April 24, 2019.

Acknowledgments: The authors would like to thank General Hospital of dr. M. Soewandhie, Surabaya for making this study possible by allowing us to access patient medical record data.

And the kind guidance from Mrs. Atika as a lecturer in study methodology and Mrs. Ilya Krisnana as a lecturer examiner that enables this study to be carried out well.

Abstract

Chikungunya fever (CF) is an arboviral acute febrile illness transmitted by the bite of infected Aedesmosquitoes. After a quiescence of more than three decades, CF has recently re-emerged as a major public health problem of global scale. A wide range of dermatological manifestations including morbilliform rash, hyperpigmentation, xerosis, excoriated papules, aphthous-like ulcers, vesiculobullous and lichenoid eruptions and exacerbation of pre-existing or quiescent dermatoses had been observed frequently in association with CF. Such atypical features may help in the clinical diagnosis of CF. Method: A total of 150 patients (59 males and 91 females) with cutaneous manifestations of CF were enrolled in the study Results: Out of all, 21 were children with minimum age of one month in the study. Females outnumbered males in the study. The most common cutaneous finding was generalized mobilliform rash. Localized erythema of the nose, genital ulceration and toxic epidermal necrolysis-like lesion sparing mucosae were the other interesting findings. Various types of hyperpigmentation were observed with unique nose pigmentation in a large number of patients. Vesicles and bullae were seen in few infants. There was flare up of pre existing skin lesions of psoriasis and lichen planus. Conclusion: To conclude, a plethora of mucocutaneous manifestations were noted in cases of chikungunya disease with striking nose pigmentation and genital ulcers.

Keywords: *Chikungunya, mucocutaneous manifestations.*

Introduction

'Chikungunya' (CKG) owes its origin to 'Kungunyala', a word derived from the Makonde language of Tanzania, which means "that which bends up", relating to the stooped posture adopted by these patients due to incapacitating polyarthralgia or arthritis. It is caused by an arbo virus of same name transmitted by the bite of Asian tiger mosquitoes Aedes aegypti and Aedesalbopictus. The Alpha virus genus consists of 30 species of arthropod borne viruses. [1]The first case of CKG was reported in 1952 from Tanzania. Since then, chikungunya outbreaks have been reported in various parts of Africa and Asia. Major epidemics of CKG occur cyclically and a disease free period of several years or decades may exist between the outbreaks. Here with this study, we describe the Dermatological manifestations in CKG patients treated at the outpatient departments of our allied institute.

Materials and Method

Patients attending the OPD of Medicine, Dermatology and Pediatrics of Rama Medical College and those who attended the camps organized at the suburban areas during the epidemic of CKG from August end to the mid of November 2016were included in the study. It was a prospective, descriptive study. Diagnosis of CKG was made based on the criteria put forth by the National Institute of Communicable Diseases, Directorate General Health Services, India. [2] The criteria were an acute illness characterized by the sudden onset of fever and several symptoms such as joint pain, headache, backache, photophobia and eruption during an epidemic of Chikungunya fever in the absence of confirmatory serological tests. A total of 150 cases who fulfilled the above criteria were included in the study.

Results

Out of 150 patients, females 91(60.66%) outnumbered males 59(39.33%). The youngest patient was only I month old and the oldest was 85 year old man. Maximum patients were in the 30-40 year age group, the mean age being 35.26 years. There were 21(14%) children out of which 11(7.33%) were infants. The most common skin lesion was erythematous rash in 86(57.33%) patients of which the macular rash predominated in 45(30%). Most of the skin lesions developed during the acute phase of the disease, two to three days after the onset of fever (75.22%). Skin lesions along with fever were observed in 11.23% and preceded fever in 3.5%. Various types of pigmentation were observed, the most common site being the nose. Two patients had tender, deep-seated nodules scattered over the distal part of the extremities (erythema nodosum type). Two patients had targetoid lesions over the extremities and trunk simulating an erythema multiform-like eruption. Six patients had generalized urticarial eruptions. Flare up of pre-existing rashes of psoriasis and lichen planus was noted in five and six patients respectively. Other lesions were vesicles and bullae over the extremities in 17 (11.33%). Only one infant (0.66%) had vesicles and bullae followed by peeling clinically mimicking toxic epidermal necrolysis.

Oral mucosal involvement was found in 18 (12%) patients in the form of multiple aphthous ulcers and angular cheilitis. One patient (0.66%) had penoscrotal ulcers. Mucosal lesions lasted for 7-10 days and subsided completely without any sequelae. Conjunctival suffusion was present in 9(6%).No nail findings were seen. Skin lesions subsided without any sequelae in the majority except pigmentation in 55 patients (36.66%).

Discussion

Chikungunya fever (CF) is an acute viral illness caused by an arbovirus of the same name transmitted by the bites of Aedes mosquitoes. Documented first time from an outbreak in Tanzania in 1952,[1,2] explosive outbreaks of epidemics of the disease have occurred after periods of long quiescence in different parts of the world. After an extensive outbreak during the beginning of the current millennium in the French territory of Reunion Islands in the Indian Ocean, CF has been reported from almost 40 countries from different regions of the world.[3]

India has been affected by chikungunyafever (CF) every two to three decades since the 1960s.[4]The pandemic that occurred in several parts of the globe in 2005 resulted in huge outbreaks in India leading to major public health concern in the country. [5], [6], [7]In 2010 also, India witnessed an outbreak[8] and after that CF had been in a decline; only sporadic cases been reported. However, in August 2016, another massive outbreak broke in India resulting in thousands of households being bedridden. The disease has affected millions of people and left many with crippling disabilities.

The re-emergence of CF has been attributed to a multitude of factors including mutation of the virus, absence of herd immunity, lack of efficient vector control activities and globalization and emergence of another vector, A. albopictus in addition to A. aegyptii as an efficient transmitter of Chikungunya virus.[9]

CF may affect people of all age groups with an equal gender distribution. In our study CKG was seen in a 1 month old infant uptoa 85 year old man. Vertical or materno-fetal transmission of CKG has not been observed in our study which was otherwise seen in an outbreak at La Reunion island. Females outnumbered males in our study while males predominated in other studies.[10],[11],[12],[13] Both sexes were equally affected in another study.[14] After an incubation period ranging from 3 to 12 days, there is usually an abrupt onset of high fever alongwith severe polyarthralgia, myalgia and mucocutaneous rash. Other findings usually seen are conjunctival suffusion, persistent conjunctivitis, cervical or generalized lymphadenopathy. The swollen and tender joints frequently involve the small joints of the hand, wrist and ankles but may also involve the larger joints such as knee and shoulder in some patients.[15]

Other clinical manifestations of CF may occur in the forms of photophobia, retro-orbital pain, vomiting, diarrhea and neurological affection such as meningeal syndrome and acute encephalopathy.[3] A wide array of skin and mucous membrane lesions have recently been documented during the various epidemics.[13],[14],[16],[17] We have reviewed various dermatological manifestations of CF in this article.(Table 1).

Table 1. Dermatological manifestations of Chikungunya

Mucocutaneous Manifestations	No. of patients (%)
Erythematous macules	86(57.33)
Maculopapular	45(30)
Vesicles and Bullae	17(11.33)

Mucocutaneous Manifestations	No. of patients (%)
Desquamation	2(1.33)
Ten like	1(0.66)
Papular	5(3.33)
Urticarial	6(4)
Purpuric	6(4)
Aphthous ulcer	9(6)
Angular chelitis	9(6)
Penoscrotal ulcer	1(0.66)
EM like	2(1.33)
Conjunctival suffusion	9(6)
Pigmentation of skin	82(54.66)
Erythema nodosum	2(1.33)
Edema of hands and feet	45(30)
Flare up of psoriasis	5(3.33)
Flare up of Lichen planus	6(4)
Localized erythema of nose	15(10)
Petechiae	5(3.33)

Dermatological Manifestations: The Dermatological manifestations of Chikungunya may occur in about 40-50% of all cases.[18],[19] The most common dermatological manifestation observed in Chikungunya patients is morbilliform eruption.[14,17] The appearance of rash is usually observed 3 to 5 days after the onset of fever and subsides within 3 to 4 days usually without any sequelae. The rash is asymptomatic in about 80% of the patients. Few patients may complain of mild pruritus.[14] The eruption most frequently appears on the first 2 days of onset of fever but may appear simultaneously with the fever or after defervescence.[14] The first site of appearance of the skin rash is most frequently the upper limbs followed by the face and trunk.[14] It may involve ear lobes and neck too.[15] Recurrent crops of lesions can occur as a result of intermittent viremia.[11],[20] In our study, erythematous macules were the most common presentation which developed abruptly after the first two days of fever and subsided within four-five days. Most of the patients had generalized maculopapular rash. Localized erythema of the nose was seen in 10% of cases as reported in other study also.[13] In 98.6% of the cases, skin lesions subsided without any sequelae except in 1.33% patients who developed desquamation of skin of palms and soles. Pruritus was present in 72% of our patients. These exanthems were associated with edema of hands and feet in 30% of our patients similar to the observation by others.[20],[21]

Different types of pigmentation have been reported in CKG patients including centrofacial and freckle-like, diffuse pigmentation of face, pinna and extremities, flagellate pigmentation and pigmentation of existing acne lesions.[13] The second most common presentation in our study after erythematous rash was hyperpigmentation of skin, seen in 54.66% cases unlike one study where it was the most common presentation.[13]Nose was the most common site affected, as noticed by others also.[17],[22] In our study, various patterns of pigmentation were seen including diffuse, melasma-like over the face, periorbital, flagellate patterns on the trunk, extremities and abdomen and palmar pigmentation. Mechanism of pigmentation could be post inflammatory.[11] An increased intraepidermal melanin dispersion/retention triggered by the virus has been postulated as a cause for pigmentation in previous study.[13]

Acute intertrigo-like lesions and genital ulceration are other distinctive manifestations of CF.[16] The patients usually develop these ulcers about 2-5 weeks after the onset of fever. The ulcers are usually 1-3 in number, 0.5-2 cm in size, oval or asymmetrical in shape, punched-out, deep-seated with undermined edges showing healthy granulation tissue in the floor and erythema and thickening of the surrounding skin. These lesions are self-limiting.[16] In our study, 1-2 tender, discrete and oval ulcers of 1-1.5 cm size, with irregular margins on the peno-scrotal junction was observed only in one patient. Aphthae-like erosions, ulcers and cheilitis were observed in 12% of the cases.

Flaccid vesiculobullous lesions in infants have also been reported.[11] Vesiculobullous lesions appeared around the fourth day of fever over the lower limb and spread to involve the perineum, abdomen, chest and upper limb.[11] Generalized erythema, maculopapular rash and skin peeling were among the other dermatological findings in the infants. A high incidence of peripheral cyanosis (without any hemodynamic alteration) had been observed among the infants in previous study.[11] In our study, vesicles and bullae were seen in 17 patients of which 5 were infants. Only one infant presented with vesicles and bullae followed by desquamation resembling TEN. The lesions subsided in three-four days. Peripheral cyanosis was not seen in any of the patient in our study.

Hemorrhagic manifestations have been reported in 11% of CKG cases. In one study, multiple ecchymotic patches and subungual hemorrhages were noted in six children and three adults.[13] In our study, petechiae were

noted in 5 patients as seen in previous study also. [23] Two patients had erythema multiforme-like lesions.

Exacerbation of psoriasis in remission[13],[17] unmasking of previously undiagnosed leprosy with type I reaction and accentuation of melasma,[13] and lichen planus[17] have been documented. In our study, flare up of psoriasis and lichen planus was seen in 3.33% and 4 % of the cases respectively.

Nail changes occur very rarely. Only a few cases of subungual hemorrhage have been reported in the literature. In our study, nail changes were not seen. The nail changes may be secondary to inflammation of the nail matrix, reduced adrenocortical activity secondary to infection.[16] Conjunctival suffusion was seen in 6% of the patients in our study.

Although the acute febrile illness caused by the Chikungunya virus remits spontaneously without any sequelae in most patients, the joint manifestations may persist for a prolonged period of time. Persistent joint affection has been described to occur in about 12% of patients in the forms of residual stiffness without pain and persistent painful restriction of joint movements.[24] Neurological and emotional sequelae have also been described.[3] Hyperpigmentation of skin may persist for months after the remission of CF especially nasal pigmentation. Xerosis has also been seen to have prolonged course.

As no vaccine is available for Chikungunya virus till date, prevention is the best measure to prevent transmission. Using mosquito repellants, nets, wearing full sleeves clothes minimize exposure to the mosquitoes. Maintaining environmental hygiene and sanitation by avoiding unnecessary water collection in or outside house prevent breeding places of mosquitoes. During an outbreak, spraying with 2% pyrethrum in high-risk areas is recommended.[25]

Conclusions

A wide variety of dermatological manifestations have been observed in recent epidemic of CKG. Genetic mutations in the glycoprotein envelope (E1) gene of Chikungunya virus and wider sequence diversity are postulated to be responsible for varying and newer clinical manifestations of the disease in each epidemic.[11] The abundance of Aedesalbopictus and mutations in may be the contributory factors for repeated outbreaks.[26] Nasal erythema, pigmentation over nose and genital ulceration were distinctive features in our study. The characteristic melasma like pigmentation of nose in CKG and its persistence for about three-six months after an attack of CKG helps to make a clinical and retrospective diagnosis of CKG. Hence, this may be considered as a marker of CKG.

'My Live is Meaningful and Adherence to Antiretroviral Therapy' Men Who Have Sex with Men (MSM) who Live with HIV/AIDS; Mixed Method

Yafi Sabila Rosyad[1], Hema Malini[2], Rika Sarfika[2]

[1]STIKes Yogyakarta, Daerah Istimewa Yogyakarta, Indonesia, [2]Andalas University, Padang West Sumatera, Indonesia

Abstract

Purpose: To identify the distribution of meaning in life frequency and adherence to antiretroviral therapy (ART) as well as to perceive and explore the association between meaning in life and adherence to antiretroviral therapy (ART) of HIV-seropositive within MSM in Padang City, West Sumatra, Indonesia.

Method: This research used a mixed method with an approach of exploratory sequence design, which was in quantitative stage through a cross-sectional design approach that intended to know the relationship between variables. 102 sample size. In the qualitative stage, the researchers used the conceptual content cognitive map (3CM) method as a data retrieval technique and then continued with the interview.

Results: Characteristics of MSM in West Sumatra more than half were gay with early adulthood who were mostly on ART treatment less than one year. Almost all MSM were middle and upper educated and they worked in sixteen sectors of employment in which the private sector was the largest. Most MSM had a meaningful life. More than half of MSM were discipline to go through ART treatment. There was a significant correlation between the meaning in life and the adherence of ART p (0,000) with the identification of several aspects that related to the meaning in life and ART adherence. They were spiritualism, lifestyle, psychological, life purpose, life achievement, knowledge and motivation.

Conclusion: The importance of meaning in life within HIV-seropositive MSM that might influence the ART adherence. Therefore, the researchers recommend to conduct a compliance monitoring activity and provide logotherapy for MSM whose life is not meaningful.

Keywords: *MSM, Meaning in life, ART adherence, HIV/AIDS, 3CM.*

Introduction

The use of ARV requires a high adherence rate of 90-95% in order to achieve therapy success and can prevent the emergence of drug resistance[1,2]. WHO has a target that 90% of People Living with HIV/AIDS (PLWHA) already underwent ART by 2016, but the target realization is only 53%. PLWHA who undergo antiretroviral therapy is increasing. In 2016, there are 19.5 million or about 53% of the total number of PLWHA and in mid-June 2017 the number has progressed to 20.9 million or about 56.9% of the total number of PLWHA [3]. Meanwhile, PLWHA in Indonesia who have undergone ART based on Ministry of Health report (2016), in 2015 there were 63,066 people where 2,056 of them experienced ART on the second line and by 2017, PLWHA who had accessed antiretroviral therapy were 77,780 people where 2,374 people were on ART on the

e-mail: rosyad2yafi@gmail.com

second line. From the data above, we can conclude that there are still many PLWHA who have not accessed ART, while the number of PLWHA in the second line shows improvement from year to year[4].

According to research by Audet, Wagner, & Wallston (2015), meaningfulness of life by PLWHA associated with the psychological welfare of patients[5]. There has been no research on the relation of meaning in life toward ART, but based on research conducted by Corless et al.,(2006)South Africa. OBJECTIVE: Health care provider concerns about persons with active TB defaulting on medications led to a study of adherence among persons receiving anti-tuberculosis therapy and, specifically, the relationships between meaning in life, life goals, sense of coherence, social support, symptom presence and intensity and adherence in individuals diagnosed with TB. DESIGN: A cross-sectional, descriptive design was used to gather self-reported data from TB-infected individuals who were enrolled in out-patient clinics. Data were collected from 159 Zulu and/ or English-speaking persons who agreed to participate in the study. RESULTS: A significant relationship was found between higher life goals and adherence to TB treatment (P = 0.027, about the relation of meaning in life to TB treatment adherence, it can conclude that there is a relationship between the meaning in life and the level of TB treatment adherence[6]. The meaning of life is a daily experience in life that is real [7] in both pleasant and unpleasant situations [8] and if someone can live every event to meets then his life will be happy [9]. The feeling of happiness can be achieved if someone who can achieve his life goals [10].

Researchers in preliminary study at NGOs Taratak Jiwa Hati with interview six participant find that all PLWHA are still difficult to remember to consume medicine and sometimes late to consume it and there are still MSM who feel their lives are meaningless. This study is important to undertake because it can give a description of ART adherence and the meaning in life of HIV-seropositive MSM. This study aims to identify the characteristics of HIV-seropositive Men who have sex with men (MSM), the distribution of meaning in life frequency and adherence to antiretroviral therapy (ART) as well as to perceive and explore the association between meaning in life and adherence to antiretroviral therapy (ART) of HIV-seropositive within MSM in Padang City, West Sumatra, Indonesia.

Material and Method

This research was mixed method through explanatory sequel design approach, where the qualitative data that was obtained in the research will help the explanation of the quantitative data result[13]. In quantitative phase, researchers used a cross-sectional design[13]. Total sampling use in this research with 102 Sample size MSM with HIV at NGOs Taratak Jiwa Hati West Sumatra Indonesia. Before conducting the research, the researchers tested the validity and reliability of the Meaning in Life Questionnaire (MLQ)in Indonesian version [14] and Morisky-8 Scale[15] also in Indonesian version and all question items of both questionnaires were valid and reliable[16,17]. In the qualitative phase, the researchers used The Conceptual Content Cognitive Map (3CM) method as a data retrieval technique. This method was a method developed by Kearny & Kaplan,[18]by using open-ended questions that were used to deeply understand the important concepts of informants' perceptions concerning the relationships between the meaning in life and ART adherence.

Results and Discussion

Research Sample: The characteristics of respondents including sexual orientation, age, education level, duration of ART and occupation. More than half of the MSM were gay with early adulthood, a majority of them were on ART for less than one-year treatment, almost all MSM were middle and upper educated and they worked in sixteen sectors of employment in which the private sector was the largest [19]. Based on research that the respondents who have sexual orientation as gay was 56 people and as bisexual men were 46 people. The age range of respondents was in the adulthood age between 25-45 years old, where this age range was for both early and late adulthood[4]. The education level of respondents, most of them, was in the middle and upper education with a percentage of 81.4%. Various researches indicated that the level of education was one of the factors that will interact in health status. Where, if a person had a higher educational status, it could reduce mortality and increase the income, even reduce twice as much mortality either directly or indirectly[20,21]. In terms of time span on undergoing antiretroviral treatment, more than half or 54% of respondents were categorized as a newbie because it was still under one year time.

Meaning in life of HIV-seropositive MSM: The majority of respondents (64.71%) had a meaningful life and about 35.29% felt a meaningless life. of the 102

respondents, 72.5% felt that there was no distinct purpose in life and almost all respondents (91.2%) were looking for something that made their life meaningful.Meaning in life had a different function for each individual, but according to Mackenzie & Baumeister (2014), the function of meaning in life could be divided into three function themes [22]. The meaning in life according to Starck(2014), was said to be the phase where a person reached his life goal [10]. According to Audet et al., (2015), the low meaning in life indicated non-adherence ART and provided a stimulus of management for handling the suffered disease[5].We were able to analyze that most respondents had been able to find the meaning of their lives although the meaning in life that was found was from an unpleasant experience. The need for counseling to improve the meaningfulness of life of seropositive MSM (35.9%). By doing so, MSM population especially seropositive one will get more external support or motivation and can improve their meaningfulness in life.

ART treatment adherence of HIV-seropositive MSM: From the research results obtained that 57.8% respondents were adherence to antiretroviral therapy and the rest did not comply as much as 43 respondents or 42.2%. This level of adherence was seen from the accuracy of the dosage and the frequency of time-consuming ARV. According to Bangsberg, Kroetz, & Deeks, (2007), ART adherence should be observed to discern the compliance level of the treatment, as some studies indicate that with treatment adherence of (95%) or more indicates the effectiveness of antiretroviral therapy [23], but on adherence (75%) shows a rise of viruses with retention against drugs [24]. Some patients fail to maintain ART adherence[25].Treatment and handling management of HIV are part of the management of chronic diseases, which have principles of medication adherence, prevention of drug retention and morbidity prevention management [25]. This condition becomes a challenge for health workers. Nurses can maximize counseling services particularly for HIV counselor and psychiatric nurses that can provide special therapies to turn negative behaviors into the positive. Apart from health workers, peer advocates also need to improve their role to remind the companions to take the drugs in a timely and appropriate dose given.

The relationship of meaning in life with ART adherence treatment within HIV-seropositive MSM:

Table 1: The relationship of meaning in life with ART adherence treatment within HIV-seropositive MSM

Meaning in life	ART adherence				Total		p	OR (CI95%)
	Non-adherence		Adherence					
	f	%	f	%	f	%		
Meaningless	31	86.1	5	13.9	36	100	0,000	27,90(8.98-86.82)
Meaningful	12	18.8	54	81.8	66	100		

Table 1 showed that there was a relationship between meaning in life and ART adherence. When a person whose life was meaningless will have 27.90 times risk to be non-adherence in undergoing antiretroviral therapy than a person whose life was meaningful. The exploration results obtained 23 statements which consisted of 7 categories. The category are the purpose of life, the achievement of life, knowledge, motivation, spiritualism, lifestyle and psychological.

Farber et al (2003), the meaning of the success of good treatment is directly proportional to the high expectation and inversely proportional to the level of depression [26]. There has been no research on the relation of the meaning in life to the level of ART adherence, but based on a research that conducted by Corless et al (2006), about the relation of meaning in life to TB treatment adherence, it can conclude that there is a relationship between the meaning in life and the level of TB treatment adherence.[6]

The exploration of the relationship between the meaning in life and ART adherence can occur due to the fulfillment of the basic components of the formation of meaning. According to Mackenzie & Baumeister (2014), there are four basic components that form the meaning in

life. First is the necessity for a purpose of life which can be categorized into results attainment and fulfillment of more abstract desire[22]. The exploration result from this life purpose component was that the participant had a life purpose to get married "... Although I am an LGBT, I have a plan to have a wife (P2)".

The life accomplishing of each participant was unique and different in interpreting the achievement of their life. *"...Can overcome all by thinking positively... experiencing the life...just like before HIV...(P1)"*.

The other achievement of the meaning in life was always being motivated to experience the life "*...Always keep the spirit, always optimistic and not pessimistic... (P3)"* In addition, the participants also live his life by becoming a better person *"...experiencing the life...by becoming a better person...(P4)"*.

The next necessity is trust and faith. Participant's spirituality indicated the existence of belief or faith by placing his trust in God *"...Pray regularly...ask God by tahajud prayer (Moslem's prayer near midnight), what is the crux of this problem so that it can be solved well (P3)"*. Participants believed that by counseling their life purpose can be achieved, following the participant's statement;

"*...According to the hospital, as a person with HIV, I can have a wife and have offspring without spreading the disease by doing the program (P2)"*

The last necessity is that one must have positive self-esteem. The meaning in life according to Starck (2014), by having a sensitive feeling with the experience of how to love his life[10].

"*...meet other people living with HIV..feeling no burden of thinking and ... should be motivated in undergoing this antiretroviral therapy.. there is a desire to behave better again ... optimist to maintain health ... be firm in facing this life and keep struggling do not get desperate (P3)*".

The freedom to choose what the participants did was to live a healthier life*"...enough exercise, a good diet and have a deeper understanding of what HIV is (P2)"*. Human suffering is the third concept of the meaningful theory.

"..with despairing by not taking ARV (P3) and why doing a healthy life while I've HIV and no one willing to befriend me, to approach me...(P2)".

The uniqueness of a person's meaningful life that is stimulated by various things ultimately can make someone adherence to undergoing antiretroviral therapy. However, to gain meaningfulness of life, one must be able to accept who they are and where their position now. The meaningfulness of life can be obtained not only in a pleasurable event but also be found from unpleasant events. HIV-seropositive is an unpleasant experience for everyone especially the respondents. Thus, health workers need to assist respondents in order to rediscover the purpose of their life so that they have the meaning in life as before HIV-seropositive.

Conclusion

PLWHA adherence to consume ART was influenced by the meaning in life, where, when PLWHA had a clear purpose that he wanted to accomplish in life, then that PLWHA will adherence to consuming ART. Meanwhile, PLWHA adherence was also influenced by peers, information attainment and self-motivation. This research provides important suggestions for health workers to be actively involved in enhancing the motivation of PLWHA, especially MSM to behave openly so that the quality of life monitoring can be done.

Abstract

The health-related quality of life (HRQOL) has been considered as a relevant measure of prognosis in patients undergoing palliative measures for cancer.

Aim: To assess the HRQOL after radiofrequency or TACE for patients with unresectable HCC. Method: this prospective study included 99 out of 163 patients with HCC scheduled for radiofrequency or TACE. Each patient underwent full clinical history, examination and laboratory investigations in addition to HRQOL questionnaire before and 3 months after the procedure. The SF-36 questionnaire was used to measure 8 domains of health. Results: there was an improvement of all parameters of HRQOL after 3 months. (Physical functioning ($p < 0.00$), Physical health limitation ($p < 0.005$), Emotional problem limitation ($p < 0.001$), Energy/fatigue ($p < 0.005$), Emotional wellbeing($p < 0.005$), Social functioning($p < 0.005$), Pain ($p < 0.005$), General health ($p < 0.005$) and total score ($p < 0.005$). univariate and multivariate analysis indicated that younger age was associated with improved HRQOL after successful treatment.

Conclusions: Successfully TACE or radiofrequency was associated with improved parameters of HRQOL 3 months after the procedure

Keywords: *Hepatocellular carcinoma, Radiofrequency, TACE.*

Introduction

Liver cancer is the fifth most common cancer and the second most frequent cause of cancer-related death globally, with 854,000 new cases and 810,000 deaths per year, accounting for 7% of all cancers[(1)]. Hepatocellular carcinoma (HCC) represents about 90% of primary liver cancers and constitutes a major global health problem.

e-mail: alym6690@gmail.com

The incidence of HCC increases progressively with advancing age in all populations, reaching a peak at 70 years [(2)]. The increasing incidence of chronic HCV, chronic HBV and non-alcoholic fatty liver disease (NAFLD) are important factors in increasing the incidence of HCC. There is accumulating evidence that in 2030, liver cancer will be the third leading cause of cancer related death in the USA [(3)]

Surgical resection of HCC is standard form of curative therapy; however, it is possible only in a small subgroup of patients. Liver transplantation is another treatment option, reserved for end stage patients but limited option due to lack of donors and socioeconomic causes especially in developing countries [(4)]. Therapies based on radiological intervention such as radiofrequency or transarterial chemoembolization are widely used for

unresectable HCC and considered as palliative treatment with potential positive impact on prolonging survival and improving quality of life. [5-9].

The HRQOL has been considered as a relevant measure of prognosis in patients undergoing palliative measures for cancer. Recent studies have suggested using

HRQOL as an independent prognostic factor for treatment response and progression in patients with advanced HCC.[10,11]

This study aimed at assessment of HRQOL after radiofrequency or TACE for patients with unresectable HCC.

Materials and Method

Study Design: This is a prospective non randomized study at two tertiary center (Minia university hospital and Minia oncology center). Any decision for treatment of HCC was taken by hepatoma team including hepatologst, surgeon, radiologist, pathologist and oncologist. The treatment decision was based on clinical factors, imaging, comorbidities and BCLC classifications. In general smaller tumor without PVT was treated by radiofrequency and larger multinodular lesions without PVT treated by TACE. Informed consent obtained in every case.

Patients: This study recruited 183 patients with HCC on top of hepatitis C virus or hepatitis B virus related cirrhosis at the time period June 2017 February 2019. All patients were asked for informed consent. Only 99 patients included in the study after exclusion of many patients who refused to participate, had complications or lost follow up (Figure 1). Every participant was subjected to full history taking with special emphasis on age, sex, smoking, exposure risk to viral hepatitis, history of diabetes or hypertension. Thorough clinical examination was done for every participant with special emphasis on the presence or absence of fever, jaundice, organomegaly, lower limb edema and abdominal tenderness or presence of ascites. Abdominal ultrasonography was performed by using a Hetachi machine with a 3.5 MHz linear transducer commenting on the liver, spleen, portal vein diameter, kidneys, hepatic focal lesions and comment on ascites (internal echoes or adhesions).The laboratory investigations included complete blood picture, total serum proteins level, serum albumin level, total and direct bilirubin, serum alanine transaminase, serum aspartate transaminase, alkaline phosphatase, prothrombin time and concentration, serum creatinine and blood urea.

HRQOL : was assessed by validated SF-36 questionnaire. Every participant filled out the questionnaire before and 3 months after treatment. Scores were compared before and after treatment. The SF-36 questionnaire is used internationally to measure 8 domains of health: general health, bodily pain, social functioning, role-physical, physical functioning, vitality, role-emotional and mental health. The raw scores of each questionnaire were converted to scores ranging from 0 to 100, with higher scores indicating higher levels of functioning or well-being [12].

Imaging: Abdominal MDCT before the procedure and after the procedure with one month – another technique as MRI diffusion used in some cases. The imaging with contrast was done before and 3 months after the radiofrequency or TACE.Tumor response was evaluated using the size criteria Response Evaluation Criteria in Solid Tumors (RECIST) and World Health Organization criteria.

Radiofrequency or TACE : patient was kept in the hospital one day before the procedure and three days after for follow up general condition and laboratory investigation .Then follow up all lab CBC, LFTs, AFP,CT one and 3 months after procedure .

Principles of radiofrequency: in this procedure, the puncture probe has an insulated shaft and anon-insulated tip, which is inserted into the lesion under ultrasound guidance. The radio frequency energy emitted from the needle tip induces ionic agitation and frictional heat. Thus, it is the surrounding tissue, rather than the electrode itself, that produces heat energy to destroy tumor cells. Because of it sex cell entnecrotizing effect, RFA has become a highly effective, local ablative therapy for HCC[13]. Forsmall HCC, RFA was reported to have efficacy comparable tot hat of surgical resection[14]. Moreover, RFAis an effective treatment for post-resection tumor recurrence, and can be used to“bridge” patients to liver transplantation[15].

Radio frequency has some limitations. For example, when the tumor nodule is close to major blood vessels, the radio frequency energy will be carried away by the blood flow (the“heat-sink”effect), resulting in a suboptimal treatment response. Another drawback is that if the electrode tip becomes too hot during ablation,

tissue charring may lead to increased tissue impedance and a smaller thermal-ablated area.

Transarterial chemoembolization: Hepatic artery obstruction is performed during an angiographic procedure and is known as trans-arterial, or trans-catheter arterial embolization (TAE). When TAE is combined with the prior injection into the hepatic artery of chemotherapeutic agents, usually mixed with lipiodol, the procedure is known as trans-arterial chemoembolization [16].The procedure requires the advancement of the catheter into the hepatic artery and then to lobar and segmental branches aiming to be as selective as possible so as to induce only minimal injury to the surrounding non-tumorous liver. [17]. It is usual to suspend chemotherapy in lipiodol, an oily contrast agent used for lymphographic studies. lipiodol is selectively retained within the tumor and this expands the exposure of the neoplastic cells to chemotherapy. [18].

TAE and TACE are considered for patients with nonsurgical HCC that are also ineligible for percutaneous ablation, provided there is no extra-hepatic tumor spread. The main contraindication is the lack of portal blood flow (because of portal vein thrombosis, porto-systemic anastomoses or hepatofugal flow). TACE in these patients increases the risk of ischemic necrosis of viable liver and increase the risk of treatment-related death due to liver failure[18].

Results

The study included 99 patients (figure 1) who completed the study protocol and follow up. Fifty eight patients (58.6%) underwent TACE and 41 patients (41.4%) underwent radio frequency. The basic data are shown in table 1 including the age, gender, clinical and laboratory characteristics.

The changes in laboratory profile in the included patients are shown in table (2) we found that significant increase in HB after the procedure, white blood cells also increases after the procedure, platelet had significant increase in its number after the procedure, liver enzymes and bilirubin improved after the procedure and also, serum ALB shows significant increase after the procedure, prothrombin concentration also increased after the procedure..

After analysis of questionnaires, the scores of all domains of HRQOL were recorded for all patients. The changes in HRQOL are shown in table 3. There was significant changes in all 8 domains of quality of life. The physical functioning significantly improved after the procedure (<0.05*), Physical health limitation (<0.005), Emotional problem limitation (<0.001), Energy/fatigue (<0.005), Emotional wellbeing (<0.005), Social functioning (<0.005), Pain (0.005) and General health (<0.005).

Table 1: Basic data of studied population (total number : 99 cases)

Variable

Discussion

In the present study, the QOL of HCC patients who were treated with TACE alone or with RFA was evaluated to gauge the benefit of these treatment strategies.

We found a significant decrease in AFP after the procedure with agreement of previous studies [19].Our finding of significantly reduced serum AFP indicates that TACE may have significantly reduced tumourburden. A hypervasculartumour may be successfully devascularised with a dramaticfall in AFP and change in imaging on arterial andvenous phases, but the size of the tumour may remain unchanged.

The QoL is considered to be as important as overall survival and tumor-free survival for these patients [20]; i.e., there is now a focus on not only achieving long-term survival but also patients lives' in relation to their disease and treatment . Moreover, a linear relationship was found between overall HRQoL and survival; specifically, patients reporting the highest level of overall HRQoL were found to have the longest survival time, after follow up of quality of life to our patients before the procedure and 3 month after to follow the 8 domains of life quality, we found a significant changes and increase in all domains of life quality and it is in aggrement with Poon, et al,2001 who noted that the clearance of tumors not only improves the physical well-being of patients but also enhances their social and emotional health statuses and their improved relationships with physicians reflect their satisfaction with the surgical treatment [21]

Another studies found that HRQOL scores of patients with HCC were more affected by the patients' level of liver function than by the presence of HCC.[22]

The SF-36 scales that showed significant changes in the present study include mental health, bodily pain and vitality. The improvement of mental health seen in our study was theorized to be related to decreased disease burden, perceived benefit of treatment and improved sleep patterns. According to Ware and coworkers [23], the bipolar mental health scale has been the most thoroughly studied of the eight SF-36 scales, in which a 20-point decrease in the mental health range of 60–80 represents tripling of the probability of suicidal ideation and doubling of the probability of depression.

The Institutional Ethics Committee approved this study of the School of Medicine, Minia University, Egypt and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

The Effectiveness of Health Education with Audiovisual Media on the Psychosocial Skills of Adolescents in Trouble with the Law

Yuniske Penyami[1], Sri Hartini[2], Yayi Suryo Prabandari[3]

[1]The Graduate Program of Nursing, [2]Department of Nursing, Faculty of Medicine, Public Health and Nursing, [3]Department of Health Behavior, Environment and Social Medicine, the Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada

Abstract

Objectives: To determine the effects of health education with audiovisual media on psychosocial skills and to identify the dominant factors correlating with the psychosocial skills of adolescents in trouble with the law.

Research Methodology: This study used a quasi-experimental design and was conducted in two places, namely The Social Protection and Rehabilitation Center of Adolescents (BPRSR), whose adolescents served as the intervention group and the Child Correctional Institution (LPKA), as the control group. Fifty-nine (59) adolescents of 14-19 years old who were in trouble with the law were recruited as research respondents (intervention group: 26; control group: 33). The intervention group was provided with health education using audiovisual media and booklets and the control group was given health education using booklets. The intervention was carried out in 3 sessions (social skills, thinking skills and emotional skills). Each session was carried out for 90 minutes (video screening, question and answer session, role playing, sharing experiences and evaluation). The psychosocial skills were observed by 3 sources (the adolescents themselves, close friends and officers).

Results: There are differences in the scores of psychosocial skills between the intervention and the control groups assessed by the three sources (self-assessment: $p = 0.013$; close friends: $p = 0.013$ and officers: $p = 0.038$). The most dominant factor correlating with the psychosocial skills is health education using audiovisual media and booklets.

Conclusions: Health education with audiovisual media and booklets can improve the psychosocial skills of adolescents aged 14-19 who are in trouble with the law.

Introduction

The data from the Directorate General of Corrections of the Indonesian Ministry of Law and Human Rights show that in November 2018, as many as 3,100 children had legal problems, 972 were prisoners and 2,128 were inmates. As quoted from Sindonews and Tribunnews in 2015, there were 369 child criminal cases and 135 minors were involved in legal issues. A research in Nepal shows that 17.03% of adolescents have experienced psychosocial dysfunction, 9.50% are male and 7.80% are female.[1]

Imprisonment can decrease cognitive control, lower cognitive functions associated with prosocial behavior,

Corresponding Author:
Sri Hartini
Department of Nursing, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada
e-mail: srihartini.psik@ugm.ac.id

lessen emotional self-regulation which can trigger recurring criminal actions, increase negative thought patterns and angry emotions and bring about mild to severe anxiety[2,3]. Lack of psychosocial skills is one of the risk factors for social problems among the adolescents and this has a close relationship with the attainment of the psychosocial well-being of adolescents[4,5]. Good psychosocial skills will help build good social competence regarding the behavioral, emotional and motivational subscales[6]

Studies on the intervention packages of life skills training have proven that life skills training can improve the self-efficacy of psychosocial competencies with the fastest time of 10 weeks and a maximum of 3 years[7]. Life skills' training has a positive impact on the mental health of the adolescents and these skills are recommended to be included in school curricula; skills training can improve mental health of the adolescents who are addicted to drugs[6]

Life skills-based promotion programs become useful interventions for the prevention of risky behaviors among the adolescents[9]. Self-modeling videos about social skills among the adolescents with autism can generally maintain the skills that have been taught for months after the interventions and audiovisual can increase knowledge better than handouts[10,11,12]. The focus of this study were 10 psychosocial skills taken from the book entitled Communication, Information and Education for Adolescents published by the Ministry of Health of the Republic of Indonesia[13]. The skills were social skills including self-awareness, empathy, interpersonal relationships and effective communication; thinking skills including critical thinking, creative thinking, problem solving and decision making; and emotional skills including coping with stress and emotion control.

Material and Method

This research was conducted in 2 centers for the development and rehabilitation of the adolescents carrying social problems and those who are in conflict with legal cases in Indonesia. The inclusion criteria were (a) having status as a child who has legal problems, (b) aged 12-19 and (c) not having severe depressive complaints based on the notes and recommendations of a psychologist. Then the consecutive sampling technique was carried out. The number of samples in the intervention group was 26 adolescents and 33 adolescents in the control group (2 adolescents were dropped out). The drop out happened because 1 adolescent got parole and the other one was visited during the post-test.

This research lasted for 26 days. The research team consisted of 2 teachers and 2 research assistants taking master's degree in nursing and 6 observers working in each institution. Session 1 was about social skills, session 2 was about the exposition of thinking skills and session 3 was about learning emotional skills. Each session was composed of video screenings (the duration of stage 1 was 18 minutes, stage 2 was 15 minutes and stage 3 was 10 minutes), questions and answers, role playing, sharing an experience of psychosocial and evaluation and closing. For the intervention group, the health education was delivered with audiovisual media and booklets containing material of the 10 psychosocial skills. As for the control group, it was provided only with booklets and brief explanations about the contents of the booklet.

1. **Observation sheets of psychosocial skills:** The observation sheets were made based on the 10 Psychosocial Skills (consisted of 14 favorable items). The validity score was 0.888-1 and the reliability score with ICC was 0.848 in 10 adolescents. The observation sheets were assessed by 3 sources, namely the respondents, close friends and prison officers (with the same instrument). The option of not doing was given a score of 1, doing with help was given a score of 2 and doing independently was given a score of 3.

2. **Questionnaires of the knowledge of psychosocial skills:** The questionnaires of knowledge contained 25 statements that had 'true' and 'false' options. The validity and reliability tests were conducted by the researchers on 90 adolescents aged 12-19 ($r = 0.216$-0.448; r table: 0.2072; cronbach alpha consistency value: 0.705). The content validity test was conducted by 3 experts with CVI (content validity index) value of 0.789-1.

3. **Questionnaires of self-efficacy in conducting psychosocial skills:** The questionnaires contained 25 items of 3 domains (magnitude, generality and strength). The favorable items were given a score of 3 if the answer was 'corresponding', a score of 2 if the answer was 'neutral' and a score of 1 if the answer was 'not corresponding'. The validity and reliability tests of the self-efficacy were performed by Dimyati (2012) with validity values of 0.306 to 0.605 and a reliability value of 0.900.

Results

The independent sample t-test shows that there is a significant difference in the scores of the skills given by close friends between the intervention and control groups (2.04 ± 4.377 and -0.88 ± 4.321, mean difference = 2.917, CI = 1.177 – 6.068, p = 0.013). The Mann Whitney test shows that there is a significant difference in the scores of the skills according to the self-assessment in the two groups (p = 0.013, median = 1.00 and 0.00). The skills, according to the officers, are significantly different in the intervention and the control group (p values = 0.038, median = 0.50 and 0.00). According to the assessment from 3 sources (self-assessment, close friends and officers), health education is the dominant factor influencing psychosocial skills.

Discussion

Audiovisual can be combined with other method in order to achieve maximum learning goals. In this research, role playing activities help the adolescents to direct their behavior and train them to apply what has been learned from their various life problems. This is consonant with Dale Cone's learning theory stating that individuals are able to remember 50-70% of the information received after seeing, hearing and practicing[14,15]. Although the space between the intervention and the post-test was only 1 week (without follow-up), a significant effect is observed because the education is not just about delivering the materials. Nursing approaches, such as empathy and motivation were also practiced along with the health education. In the control group, there is no significant difference found in the scores of the skills before and after the booklets were distributed. The research team only explained (10 minutes) about the contents of the booklets briefly. This study also shows that booklets do not have a significant influence on the psychosocial skills of the adolescents. The research team is not sure whether the respondents read the booklets. The unstable mental condition of the adolescents in prison can also be one of the triggers for the low interest in reading among them. Coping strategies and the stressors are closely related to the emergence of mental problems and can become the predictors of crime in the future[16]. Therefore, a personal approach is urgently needed to support learning among adolescents in prisons such as motivational interviews as what has been done in the intervention group[17].

The domains of human behavior, namely cognitive, affective and psychomotor according to Bloom's theory have horizontal integration and vertical progression correlations when the learning objectives are determined by the cognitive, affective and psychomotor domains[18,19]. Increasing knowledge, perception and self-efficacy is potential to give positive influences on the adolescents in practicing the activities that have been taught[20]. Good knowledge forms good affective skills and it shapes the skills of adolescents. In this study, the affective aspect assessed is self-efficacy, which is a belief in his/her ability to succeed in doing something. Improving psychosocial competence is important because adolescents will know alternative strategies to express strong emotions, communicate strong opinions and build social image[21]. A high level of self-efficacy has also proven to be significant to lower the probability of recidivism[22]. The process and results of this study that can be recommended to be further carried out are as follows. Video can be provided if the facilities in the prison support it. The weakness of this study is that there was no follow-up and there was only one post-test. As a result, the duration of skills maintenance cannot be identified. Further research can investiagate how long the adolescents can maintain psychosocial skills. The researchers also recommend a qualitative research to illustrate the challenges and expectations of the adolescents in practicing psychosocial skills in prison.

Conclusions

Based on the assessments from the 3 sources, health education can increase the psychosocial skills of the adolescents of 14-19 years old who are in trouble with the law. The dominant factors correlating with the psychosocial skills of the adolescents is health education.

Acknowledgments: We would like to express our deepest gratitude to all the respondents who have sincerely been willing to serve as the subjects of this study. We would also thank to UGM for supporting the funding of study.

Ethical Clearance: This research was conducted after obtaining ethical approval from the Ethics Committee of the Faculty of Medicine, Public Health and Nursing (FKKMK) of Gadjah Mada University (number; KE/FK/0330/EC/2019).

Conflict of Interest: No conflict of interest has been declared by the authors.

Women's Involvement in Decision Making and Unmet Need for Contraception in Indonesia

Yunita Amraeni[1,2], Sudijanto Kamso[3], Sabarinah B. Prasetyo[3]

[1]Higher Education Institution of Health Mandala Waluya, Kendari, [2]Doctorate Student, Faculty of Public Health, Universitas Indonesia, [3]Department of Biostatistics and Population Studies, Faculty of Public Health, Universitas Indonesia

Abstract

Background: The issue of gender inequality in reproductive health has a role in determining contraceptive use in women. Gender issues related to inequality in decision making are the main context in family planning interventions. The purpose of this study is to assess women's participation in decision making and its relation to unmet need.

Method: A cross-sectional study was conducted using IDHS data in 2012. The study involved 1516 women of childbearing age (15-49 years) with married categories in areas with high unmet need (West Papua) and the lowest unmet need area (Bangka Belitung)

Results: Married women in the Bangka Belitung region have more power in decision making than married women in West Papua. Involvement in economic matters and the decision to use contraception as the most dominant factor and involvement in the household have a significant relationship with the occurrence of unmet need, as well as education, wealth and experience in using contraception related to unmet need. while age, fertility preference, husband's desire to have children and involvement in health and mobility were not directly related to unmet need.

Conclusions: Better participation in decision making is higher for women in the Bangka Belitung region than in Papua. Empowerment of women in terms of the economy and the use of contraception needs to be improved so that they have power in decision making.

Keywords: *Unmet Need, Modern Contraception, Decision Making, Involvement.*

Introduction

Contraceptive use is one of the government's policies to reduce the total fertility rate. Decline in TFR was not followed by a decrease in unmet need. Based on the 2012 IDHS data, the unmet need figure is still stagnant at 11%. Unmet need disparities still occur in every province in Indonesia. The highest unmet need reached 23.7% in the West Papua region while the lowest unmet need was in Bangka Belitung with a figure of 5,6% [6]. This is thought to have social and cultural influences that influence decisions in family planning.

Unmet need is associated with client needs that have not been fulfilled regarding the expectation of being able to delay pregnancy or the desire to be able to limit pregnancy. The desire to fulfill these needs is based on the desire/unwillingness to have children, determine the ideal number of children and use contraception[21]. Related to the existence of gender issues, it shows the occurrence of inequality in terms of equality of reproductive rights. This can be seen in the differences in the desire/ unwillingness to have children, the determination of the ideal number of children and contraceptive use between men and women as couples who should have a joint decision on this matter [14,15].

Based on the desire to have children, almost 50% of married women say they do not want to have more children (including those who have been sterilized). But around 15% of women show the fact of pregnancy

when they don't/don't want children [6]. The desire to have children and determine the ideal number of children greatly affects the subject of contraceptive use. To achieve this desire, men and women must have a decision to use contraception or not to use [11].

Indonesia is one of the developing countries that is still influenced by social and culture which places women in a position below men [14]. This affects women's participation in making decisions in all aspects. Indonesia is a patriarchal society that believes that women are inferior to men [23].

This is supported by The Conference on Population and Development (ICPD) in Cairo 1994, a testament to the commitment of the international community on issues of gender, population and development with a new perspective.Decisions in contraceptive use and fertility are thought to be the influence of gender inequality especially in patriarchal societies [1]. Studies in Ethiopia show male dominance of women leads to an increase in the number of children[20]. Studies in sub-Saharan Africa also illustrate that there are indications of decision-making problems that affect contraceptive use by women without their partners knowing [3].

The disparity in the number of unmet need may be caused by the existence of a strong patriarchal system in several regions. Therefore, the aim of this study is to assess women's participation in decision making and its relation to unmet need in regions with high and low unmet need in Indonesia.

Method

Study area and setting: The cross-sectional study was conducted using IDHS data in 2012. Data measurements were carried out in two regions, namely Bangka Belitung as the area with the lowest unmet need numbers and West Papua as the highest unmet need number.

Sampling: This study involved 1516 women of childbearing age (15-49 years) with married categories. Using data from the Indonesian Demographic and Health Survey (IDHS) in 2012, the research design used was cross sectional.

Measurement: Participation in decisions is an independent variable measured using the autonomy index obtained based on the literature[4,9,12,22]. Questions related to participation followed the questionnaire in the Indonesian IDHS survey which included women's participation in decision making in terms of economy, household, mobility and health. Questions related to decision making are categorized as having high autonomy in decisions if women are involved in all aspects of decision making. Moderate autonomy if there is ≤ 2 decision aspect involvement and does not have autonomy in the decision if there is ≤ 1 decision aspect involvement. Contraceptive use is a dependent variable with unmet need categories and not unmet need. Unmet need is indicated if women have the desire to postpone pregnancy or do not want to have more children, but do not use any contraception to prevent pregnancy. Other variables that are indirectly related to women's decision participation will also be measured such as age, employment, education, resident, fertility preference and wealth.

Statistic Analysis: Data was processed using Statistical Package for the Social Sciences (SPSS) software version 15.0. Univariable, bivariable and multivariable analysis was carried out. Chi square will be useto see the closeness of the relationship between variables and logistic regression test to identify the most significant of variable.

Result

Sosio demographic characteristics: Most of the respondents in the two regions were in the age group 25-29. The majority of married women have education at the primary and secondary levels in both regions. But in West Papua more women with higher education than in Bangka Belitung. While the economic level in West Papua is lower than Bangka Belitung (see table 1).

Reproductive Health Characteristic: Regarding contraceptive use, it turned out that the dominant women used traditional method to delay pregnancy in both groups. About 27.2% of women in Bangka no longer want children, while 22.8% still plan to become pregnant. In contrast, in West Papua, there are fewer women who do not want children (17%) compared to women who still want to add children (20.1%). For more details can be seen in table 1.

Table 1. Socio demographic variabels of married women (N= 1516)

Don’t know	90(6,3)	220(15,4)	310(21,7)

Decision making power in both area: Overall, the power of decision making in the West Papua region is lower than Bangka Belitung. There were no significant differences in decision making in the aspects of health services, household and mobility in both groups. But in the economic aspect, the involvement of women in West Papua was lower (39.6%) compared to Babel (48.1%). Likewise with the decision in contraception, as many as 27.8% of women in West Papua and 19.7% of women in Babylon were not involved in the decision.

Unmet need and decision making: Involvement in health service, household and mobility aspects in both groups showed that women without cases of unmet need had better involvement than unmet need groups. Similar to the low number of women's involvement in these three aspects, there were more women who did not experience unmet need. There are 13.9% of women in the group without unmet need involved in economic matters while in the unmet need group only around 9%. And as much as 7.5% of women without unmet need have better involvement in contraception compared to 5.2% of the unmet need group.

Discussion

The results in this study to prove the assumption of participation or involvement of women in decision making in all aspects are closely related to the incidence of unmet need.

Table 4. Logistic regression analysis: dependent variable-unmet need

	Significance	Odds ratio (95% confidence interval)

The results of this study indicate that the dominant factor affecting the unmet need is the involvement of women in decisions in the economy and contraception. This is consistent with the research conducted by another researchthat Decision-making was found to be positively associated with contraceptive use and not having unmet need for contraception[5,18].

Decisions in terms of economics influence decisions in contraceptive use, allegedly because finance affects authority. This is consistent with the study of Palamulenithat employment status factors influence contraceptive use in women[19]. This research is also found that there were no significant differences between the two regions in terms of decision making in health services and mobility. This is presumably because the government has been maximal in its efforts to equalize health both in terms of facilities and officers. While for decisions in terms of mobility, now it may have become a thing that is not rigid and taboo to do, so that cases of mobility related to visits to relatives and friends are not the dominant thing to discuss.

This study also found that low involvement in household-related decision making, economy and contraception was more dominant in the West Papua region. This is allegedly related to economic growth. This study found that the middle to upper class people based on wealth index were more dominant in the Bangka Belitung region.The situation of economic growth affects the economic level of the family. Possibly in the West Papua region, the status of work is more for men than women[15]. So that women in the region depend on their husband/partner's livelihood. This is also affects household decisions and contraceptive use.

Contraceptive use can be influenced by external factors related to the position of women in social life [9,10]. The assessment of women's position has been assessed by gender differences that place women and men in accordance with their functions and their respective roles [2]. Problems arise when there are gender inequalities that limit each other's rights [13]. Gender-based power inequalities can limit open communication between partners about reproductive health decisions and women's access to reproductive health services, which contributing to poor health outcomes The importance of partner communication is often emphasized in family planning and research programs, this is the first step in making rational fertility decision processes [17]. In developing countries some women have low bargaining positions. In fact, women who are either under collective decision making with their partners or completely dependent on the decisions of male partners on the issue affect their reproductive lives[8].

Conclusion

The findings indicate that creating conditions for women who can improve their financial status by increasing women's empowerment in terms of economy can increase autonomy in maintaining the right to reproductive health itself. This research is limited by data available to measure women's empowerment. Other limitations of this study are uses cross sectional which cannot determine the temporal relationship between two variables.

Abstract

In Indonesia, the problem of low nutritional status proportion is still a problem, despite it decline of 37.2% in 2013 and 30.8% in 2018. Southeast Sulawesi is the Province with prevalence of stunting of 27.5 % in 2018 while Kendari City with the prevalence of 28.6% of children under five included in the stunting category. In 2014 to 2015 there was a 2.2% increase in stunting children in the working area of Puuwatu Public Health Center. The purpose of this study was to determine the factors associated with the incidence of stunting among children aged 24-59 months. The type of study was quantitative with a cross sectional study approach. The sampling technique was accidental sampling, with the number of respondents was 88 toddlers. The results of statistical tests using chi square test with confidence level of 95%. The result of study obtained p value of protein intake = 0.001, p value of mother's education = 0.040, p value of father's occupation= 0.003 and p value of economic status = 0.054. That means a significant relationship with the incidence of stunting. Whereas p value of energy intake = 0,932, p value of exclusive breastfeeding = 0,116, p value of number of children = 0,840, p value of father education = 0,083 and p value mother's occupation = 0,154, thus there was no significant relationship with the incidence of stunting. Conclusion: Mothers play a significant role in toddlers's nutritional intake.

Keywords: *Stunting, Nutrition, Children, Exclusive Breastfeeding, Education, Occupation, Economic.*

Introduction

Stunting toddler includes chronic nutritional problems caused by many factors such as socioeconomic conditions, maternal nutrition during pregnancy, morbidity in infants and lack of nutrition in infants. Stunting toddlers in the future will experience difficulties in achieving optimal physical and cognitive development[1]. The percentage of short toddlers in Indonesia is still high and it is a health problem that must be addressed. Global Nutrition Report in 2014 showed that Indonesia was included in 17 countries among 117 countries which have three nutritional problems, namely stunting, wasting and overweight among toddlers[2].

In Indonesia, children malnutrition and stunting are a serious public health problem. of the 24.5 million children under 5 years, around 9.2 million (37%) experience stunting (Riskesdas, 2018)[3]. The highest number of cases is in rural areas from the national average, including West Kalimantan (39.7%), Central Kalimantan (39.6%), South Sumatera (38.9%) and the rest can be found in Sulawesi. In Indonesia, the high stunting levels are associated with a combination of complex factors including nutrition, hygiene, parenting, diet, low maternal education, inadequate maternal nutrition, low family income, low birth weight, birth distance, poor exclusive breastfeeding, hygiene inadequate and household food security[1].

The results of the Nutrition Status Monitoring (PSG) 2015 showed 23.1% of Indonesian toddlers, including the short category, with the highest percentage in the provinces of East Nusa Tenggara and West Sumatera. Southeast Sulawesi Province was 31.4%included in the stunting category in 2018 and it decreased to 27.5% compared to the previous year[4]. While in Kendari City, 28.6% of children under five is included into the category of stunting[5].

According to toddler nutrition monitoring in 2016, the very short category nutritional status of toddlers was 8.6%, short category was 20.0% and normal was 71.4%[6]. Data from the Kendari City Health Office on the prevalence of stunting in 2010 to 2014 increased from 421 per 10,000 of toddlers and increased by 2,162 per 10,000 of toddlers[5].

The Puuwatu Public Health Center data in 2014 showed 7 there were 6% of stunting toddlers, then in 2015 there were 9.7% stunting toddlers. in 2017 there were toddlers in Under the Red Line (URL) of 0.5%, low birth weight of 2.0% and poor nutrition of 0.1% [7].

In order to achieve the global stunting target for 2025, countries should begin with a situation analysis to determine how many children aged under 5 years are stunted and assess the determinants of stunting in specific geographical and social contexts, so that actions are tailored to address contextual needs. A deliberate equity driver policy targeting the most vulnerable populations is an effective strategy for reducing national stunting averages [8].

Materials and Method

The type of studywas quantitative method with cross sectional study approach. It aims to find out what factors are related to the incidence of stunting in infants aged 24-59 months in the Working Area of Puuwatu Health Center of Kendari City in 2018.

Data was obtained by measuring heighof children using microtoise, interviewing and filling in questionnaires with mothers. The results of heigh measurements then processed to obtain the nutritional status of children using the WHOstandard -2005, namely Z-score index Heigh/Age. Data on the level of energy and protein intake was obtained by filling semi-quantitative *Food Frequency Questionnaire* (FFQ), then processed with Nutri Survey 2007.

Result

Table 1. Determinants of Stunting incidence among Toddlers Aged 24-59 Months in the Puuwatu Public Health Center Working Area

Variable	Stunting incident		p value
	Stunting (n)	Non Stunting (n)	
Energy intake			
- Less	9 (42,9%)	12 (57,1%)	0,932
- Sufficient	26 (35,6%)	33 (64,4%)	
Total	35 (43,8%)	45 (56,2%)	
Protein intake

Total	35 (43,8%)	45 (56,2%)	

Primary data 2018

Discussion

Energy Intake: Energy intake is one of the variables in this study to assess the consumption of toddler food. In this study, the toddler's energy intake was divided into two namely less energy intake (<100% Daily Values) and sufficient (≥100% Daily Values)[9].

In the Puuwatu area with the majority of low-educated mothers one of the causes of stunting was mothers did not pay attention to the nutritional intake of children and these factors were supported by a low family economy. It is needed the increase of knowledge about the importance of balanced nutritional needs both in formal and informal ways and pay more attention to children's nutritional intake so that the nutritional needs of both micronutrients and macro nutrients can be adequat[10].

Protein Intake: In toddlers, protein is needed for tissue maintenance, changes in body composition and for new tissue synthesis[11]. Protein intake is one of the causes of stunting among toddlers. Protein intake can be obtained from mother's milk, but if children do not breastfeed again, protein intake is obtained from the food they eat.

Some of the fathers in Puuwatu work as traders and drivers so as to make the family economy unstable. The consequence that the mothers only fulfilling basic needs without considering nutrition intake for children due to economic constraints. This is also supported by behavior of mother who only provide unhealthy snacks, so that the children become lazy to eat healthy food. This is in line with previous study that factors such as energy intake, protein intake and parenting are related to the incidence of stunting among toddlers[12]. Research conducted by Anindita (2012) showed that there was a positive relationship between the level of protein adequacy and stunting (short children) in infants aged 6-35 months[10].

Exclusive Breastfeeding: Breast milk can meet three quarters of the protein needs of infants aged 6 - 12 months, besides breast milk also contains all essential amino acids needed by babies[11].

In Puuwatu almost all mothers did not give exclusive breastfeeding to their children, only a small proportion give exclusive breastfeeding due to breastfeeding to mothers who come out a little, some did not leave at all and family factors suggest that mothers provide additional food and busy working mothers.The results of studythat conducted by Fikadu, et al (2014) showed that duration of exclusive breastfeeding and complementary feeding method are independently associated with stunting. Thus, public health interventions has role to improve children's nutrition and must consider these determinants[13].

Number of Children: Fikadu, *et al* (2014) stated that children living in households with eight to ten [Adjusted Odds Ratio (AOR) = 4.44, 95% CI: 1.65, 11.95] and fiveto seven [AOR = 2.97, 95% CI: 1.41, 6.29] family members were more likely to be stunted than those living in householdswith two to four family members. Similarly, children living in households with three under-five children [AOR = 3.77, 95%CI: 1.33, 10.74] were more likely to develop stunting than those living in households with one under-five child[13]. Beside that other study showed that toddlers with multiple parities have a risk of 4.08 times stunting compared with toddlers who have little parity[14]

In this study included toddlers with a large number of children but not stunting. It was caused by other factors that influence the incidence of stunting, one of which was economic status. A good family economic status will affect the quality and quantity of food that will be consumed by the family.

Fathers' Education: Father's education does not directly influence to the child's nutritional intake, butt mother's knowledge is play role. This is related to how routine the visit to the posyandu to participate in counseling about child growth and nutrition needed by the child, which will increase the level of knowledge of the mother about nutrition. Mothers who have a good level of knowledge will present a food menu that suits their needs according to their age.

The study that conducted by Sarma, et. al (2017) in Multiple Logistic Regressions Assessing the low of fathers' education level has the risk of having a child with stunting of 1.03 timesonin Bangladesh[15]

The father who acts as the head of the house focuses more on how to get money rather than taking care of household needs, the lack of a father's role in contributing to helping mothers in providing nutritional intake to children is still lacking. In the Puuwatu region, some fathers are well educated but due to a lack of awareness from the father to help and remind mothers to provide good nutrition for the family. The environment that does not support the father to better understand the importance of good nutrition for the family is one of the triggers because the father does not get socialization or knowledge for family nutrition.

Mothers' Education: Mother's education is strong predictor of stunting among toddlers. The education level of mothers with mental development of toddlers has a meaningful relationship. Most of the mothers in the Puuwatu area have a low level of education which causes mothers not understand about nutritional intake and good parenting for children. The result of this study is in line with the study of Ibrahim & Faramita (2015) who stated that there was a significant relationship between mother's education level and stunting incidence among toddlers aged 24-59 months in the Barombong Public Health Center work area[16].

The lack of knowledge about stunting and misconceptions related to the impact of stunting create significant challenges to behavior change and efforts to prevent stunting in Indonesia. Knowledge and perception about vulnerability and severity of stunting are almost none among Indonesian mothers. Mothers who are aware of stunting, the majority see it as a genetic or hereditary condition and are not related to suboptimal cognitive future achievement, health and productivity [17]. Thus, increasing maternal education, knowledge of stunting and knowledge of nutrition may improve dietary diversity[18]

Father's occupation, Mother's Occupation and Economic status: In this study the work of fathers is categorized based on income, so that there are three categories, namely Services, Entrepreneurs, Civil Servants. Father's occupation is closely related to economic status. The occupation of father in the service sector tends to have an irregular income, so that the economic status is related to the ability to fulffill the family needs especially in nutritional needs.

In the study of guidance (2011) stated the same thing with the results of this study. There was a tendency for stunting toddlers to be higher in mothers who do not work compared to working mothers [19].Mothers who work outside the home can cause children to be

neglected, because toddlers are very dependent on their care or other family members. But on the other hand mothers who work can help with family income, because occupation is an important factor in determining food quality and quantity.

Kusuma and Nuryanto (2013) in their study results of multivariate analysis showed that the risk factors for stunting among children aged 2-3 years are low family economic status (p = 0.032; OR = 4.13) in East Semarang District. It concluded that low family economic status is a significant risk factor for the incidence of stunting among children aged 2-3 years[20].

Conclusion

There was a significant relationship between the level of protein intake, mother's education, father's occupation and family income level with the incidence of stunting among toddlers aged 24-59 months in the working area of Puuwatu Public Health Center of Kendari City. There was no significant relationship between energy intake, exclusive breastfeeding, the number of children, father's education and mothers occupation with the incidence of stunting among toddlers aged 24-59 months in the working area of Puuwatu Public Health Center of Kendari City.

Surface texture of modified Polyetheretherketone Compared to Lithium Disilicate Crowns in Anterior Aesthetic Zone (Randomized Controlled Clinical Trial)

Ahmed Hussin Naguib[1], Gihan El-Naggar[2], Nora Helmy Hassanen[3]

[1]Professor of Fixed Prosthodontics Faculty of Dentistry, Cairo University and Future University, Egypt, [2]Professor of Fixed Prosthodontics Faculty of Dentistry, Cairo University, Egypt, [3]B.D.S, 2006, MSc, 2012, Faculty of Dentistry, Cairo University

Abstract

Background: Crown surface texture affect final esthetic outcome upon restoring single anterior tooth which poses the greatest esthetic challenge for the clinician.

Objectives: The aim was to compare surface texture of modified polyetheretherketone (PEEK) polymer and lithium disilicateceramic crowns in anterior esthetic zone with follow up one year.

Materials and Method: Twenty-four Patients were divided randomly into two groups (group=12), each patient received either modified PEEK or lithium disilicate crown. Both materials were fabricated according to the manufacturer's instructions. Surface texture was evaluated at cementation time and after 3, 6, 9 and 12 months follow up periods by five blinded assessors to ass surface texture change using modified United State of Public Health and Service (USPHS) scores.

Results: Chi-square test was used to compare between different tested Groups. There was no statistically significant difference among time between the two groups (P-value = 1.00) regarding the surface texture of the lithium disilicateceramic and modified PEEK polymer restorations.

Conclusion: IPS e.max and modified PEEK crowns revealed excellent surface texture after one year follow up and the modified PEEK polymers can be successfully used in aesthetic anterior restorations.

Keyword: *Surface texture, modified USPHS, modified PEEK, Lithium disilicate.*

Introduction

The appearance of teeth is a complex phenomenon, affected by many factors such as lighting conditions, translucency, opacity, light scattering, surface texture, gloss and the human eye and brain influencing the overall perception of tooth color. To achieve esthetics, four basic determinants are required in sequence; viz., position, contour, texture and color. This knowledge is essential for achieving good esthetics[1].

Surface texture and luster are the most important factors affecting how light interplays with the tooth surface. A roughened surface texture will not yield as well defined an image and will scatter the light and the individual wavelengths will all bend differently yielding a substantially different spectrum returning to the eye[2].

Dental ceramics allow regular and diffuse transmission, as well as diffuse and specular reflectance

of light and therefore have the potential to reproduce the depth of translucency, depth of color and texture of natural teeth. In addition, dental ceramics have a relative good resistance to degradation[3].

Since there are no studies comparing surface texture between ceramics and new ceramic reinforced polymer, we have selected this study to compare surface texture of modified PEEK polymer versus lithium disilicate ceramic crowns in anterior esthetic zone with follow up one year.

The aim of this study: The aim of this study was to compare the surface texture of modified PEEK polymer with lithium disilicate ceramic with one year follow up.

Materials and Method

Study Design: Randomized controlled clinical trial.

Study Location: This was a teaching hospital based study done in Department of fixed prosthodontics clinic, at Faculty of Dentistry, Cairo University, Cairo, Egypt.

Study Duration: October 2018 to November 2019.

Sample size calculation: The sample size was estimated based on paper by Batson et al., 2014 [1] the clinical performance within each subject group was normally distributed with standard deviation 38.2. If the true difference in the experimental and control means is 45.3 mm, we were needed to study 12 patients in each group to be able to reject the null hypothesis that the population means of the experimental and control groups are equal with probability (power) 0.8. The Type I error probability associated with this test of this null hypothesis is 0.05. The sample size was calculated by PS program.

Subjects & selection method: Patients were divided into two groups (each group had 12 patients) according to material used as follows:

Group I (N=12 patients): Pressed E-max coping veneered with E-max veneering system (IvoclarVivadent, Liechtenstein).

Group II (N=12 patients): Modified PEEK Pressed (Bio HPP: Bioactive High Performance Polymer) coping veneered with Visio.lign (Bredent, Germany).

Procedure Methodology: Written informed consent was obtained from all patientsunder the supervision of Research Ethics Committee, Faculty of Oral and Dental Medicine, Cairo University.

Intra oral examination, photographs, diagnostic casts and scaling and polishingwere performed for each patient before shade selection. The color of the tooth was recorded visually using VITA 3D-Master shade guide system accordance to the contra-lateral/adjacent tooth under different light conditions: natural day light and color corrected light with the help of five prosthodontists (3 females and 2 males) that performed Ishihara's test to determine color deficiency. Their results showed no color blindness. Shade was also confirmed with Vita Easy shade V spectrophotometer. Shade mapping was performed to ensure correct placement of different shade effects and characterizations. Also preoperative photographs were sent to the ceramist to ensure mimicking matched surface texture and luster.

All ceramic anterior tooth preparations were introduced to ideal preparation parameters with deep chamfer finish line. It was created 1.0 mm diameter supra-gingivally along the free gingival margin using a tapered diamond stone with a round end. The shade of the prepared abutment tooth was recorded visually using the IPS Natural Die Material shade guide (Ivoclar Vivadent, Liechtenstein)under natural day light and color corrected light (Flexipalette, Smile line, Switzerland) in order to fabricate a die mimicking the oral situation for optimum desired final esthetic results. Final impression was taken using vinylpolysiloxane addition silicon (Express PVS impression, 3M ESPE, Germany) in plastic stock trays.

Lithium Disilicate and Bio HPP crowns were fabricated into tooth shape supporting framework by pressing technology then veneered with theveneering system for each of appropriate shade according to manufacturer's instruction.

Esthetic try-in of unglazed lithium disilicate crowns was performed using a water-soluble gel (clear glycerin) under natural day-light and color corrected light then confirmed with the Vita Easy-shade V spectrophotometer. Stain and glaze firing were performed after verification and adjustments (if needed) in the ceramic furnace.

Both lithium disilicate and Bio HPP fitting surfaces were treated according to manufacturer's instruction. Then, isolation was granted through the use of rubber dam.Bonding procedures were done using self adhesive translucent luting resin cement according to manufacturer's instruction. All clinical steps were performed for Group II: Bio HPP crowns in the same

manner as previously mentioned for Group I: E-max crowns.

Assessment of surface texture: Five evaluators assessed the outcomes of each group.

Surface texture was evaluated in scores by sharp explorer and visual mean according to the modified USPHS:

Alpha: Surface is smooth as the surrounding,

Beta: Surface is rough than the surrounding,

Charlie: Surface is very rough avoiding avoid movement of the explorer,

Delta: New restoration is needed.

Scores of the patients were recorded immediately after crown cementation, 3, 6, 9 & 12 months after review for aesthetics.

Findings: Data were presented as frequencies and percentage values. Chi-square test was used to compare between different tested Groups.

The significance level was set at $P \leq 0.05$. Statistical analysis was performed with IBM® SPSS® (SPSS Inc., IBM Corporation, NY, USA) Statistics Version 23 for Windows.

Demographic Data: The present study was conducted on 24 patients, 15 Females and 9 males. The mean and standard deviation values for age were 30 with a minimum of 25 and a maximum of 40.

According to the USPHS scores, results of comparison between the two groups for The Frequency (N) and Percentage (%) for surface texture`s assessment are presented in table (1) and figure (1).

At T0 (at base line): Both all restorations of E- max Group and Bio HPP Group showed (100%) Alfa score with no statistically significant difference at base time between the two groups (P-value =1.00).

At T3 (after 3 month): Eleven restorations of Bio HPP Group showed (91.7 %) Alfa score while one restoration showed (8.3 %) Beta score. All restorations of E- max Group showed (100%) Alfa score.

There was no statistically significant difference among time between the two groups (P-value =1.00).

At T6 (after 6 month): Eleven restorations of Bio HPP Group showed (91.7 %) Alfa score while one restoration showed (8.3 %) Charlie score. All restorations of E- max Group showed (100%) Alfa score.

There was no statistically significant difference among time between the two groups (P-value =1.00).

At T9 (after 9 month): Eleven restorations of Bio HPP Group showed (91.7 %) Alfa score while one restoration showed (8.3 %) Charlie score. All restorations of E- max Group showed (100%) Alfa score.

There was no statistically significant difference among time between the two groups (P-value =1.00). Restorations in E- max Group showed the highest prevalence of Alfa score followed by Bio HPP Group. Restorations in Bio HPP Group were the only restorations that had Charlie score. All group showed a no prevalence of Beta score.

At T12 (after 12 month): Eleven restorations of Bio HPP Group showed (91.7 %) Alfa score while one restoration showed (8.3 %) Charlie score. All restorations of E- max Group showed (100%) Alfa score.

There was no statistically significant difference among time between the two groups (P-value =1.00).

Discussion

The increasing esthetic expectations in daily life directly affect the color, texture, techniques, materials and treatment procedures in dentistry, in order to achieve an esthetic successful restoration with perfect appearance.

In this study full coverage restorations were fabricated from two different materials: IPS e.max Press coping veneered by IPS e-max Ceram (lithium disilicate crystals embedded in a glassy matrix) ceramic material[4] and Bio HPP (Bioactive High Performance Polymer based on polyether-ether-ketone (PEEK) polymer with

20 % ceramic filler veneered by Visio.lgin composite (50% opalescent ceramic fillers embedded in high strength oligomer matrix))[5].

IPS e.maxPress is biocompatible lithium disilicate glass-ceramic ingots a patented material manufactured by IvoclarVivadent[4]. They offer the fit, form and function which is expected from pressed ceramics[6].

A modified PEEK-based polymer with 20% ceramic fillers (Bio HPP; Bredent GmbH) has been recently introduced in dentistry (the grain size of 0.3 to 0.5 μm) for better polishing of the restorations[7,8]. Because of their micro size, homogeneity is achieved in the macrostructure of the polymer[9]. The high degree of polishability of the material results in a lack of plaque retention and color stability over time[10].

Bio HPP (Bioactive High Performance Polymer) provides excellent biocompatibility, high temperature resistance, chemical stability, wear resistance and low plaque affinity[11]. Bio HPP is particularly suitable for patients with allergies because the solubility of the polymer in water is very low <0.3 mg/mm3[12]. Extremely low weight is shown by the finished Bio HPP restorations, which is considered as an advantage by the patients. Bio HPP can be an alternative to chromium-cobalt dental alloys (Cr-Co) because it is lighter and does not cause corrosion[13].

The evaluation of the outcome was performed by experienced evaluators who were blinded and did not know the crowns belonged to which group also the statisticians as well as the patients were blinded. Explaining the results of the E-max Group might be due to followed restricted glazing protocol (esthetic try in and adjustments was performed before glazing) for glass ceramic according to manufacture instructions which allow smooth glazed surface of restoration and this was performed prior to the luting procedure and involves reheating the ceramics according to Pinar karsolglu et al., 2014[2].

Concerning IPS e.max results,Mazen et al., 2017[14]found the excellent surface texture with the use of layered lithium disilicate restorations

This is come in accordance to Motroand Kursoglu, 2012[15] who found that ceramic staining was related to surface texture changes after different surface treatments. There was an 83% positively significant relationship between surface roughness (Ra) and ΔE values. Values were the lowest for glazed and reglazed group. Rough surfaces stained more after coffee immersion than did smooth surfaces. He concluded that surface treatments affected surface roughness and color stability and smooth surfaces showed better color stability after discoloration.

Also Yunlong Zhang, et al 2004[17] who found in his vitro study, total porosity of specimens prepared using 4 different veneering porcelain systems, was sensitive to powder/liquid ratio; whereas translucency was found to be insensitive to powder/liquid ratio.

AlsoRusu et al., 2018[17] found that Lithium disilicate veneers showed similar stability (regarding surface texture) regardless the processing method after 6 month.

This was contradicting to Karla et al., 2015[18] who found the difference in translucency parameter (TP) values among colors was evident in the IPS e.max Ceram Dentin material, both before and after exposure to acid and in the IPS e.max Press material. CAD/CAD specimens showed uniform TP values. They concluded that different types of glass-ceramics showed significant difference in TP values both with respect to the fabrication technique and color. Exposure to a corrosive medium did not result in a statistically significant change of TP values.

Explaining the results of the Bio HPP Group, this is might be due to the followed restricted polishing laboratory protocol for the veneering composite according to manufacturer instruction. Alsothe staining resistance may be explained by the amount and dimension of the filler particles (Visio.lign has 50% ceramic nanofillers) and nature of the resin matrix.

Our results was in accordance to Anja Liebermann et al., 2016[19] who found PEEK showed the lowest solubility and water absorption with subsequent degradation that affect color stability compared to other polymers.

Contradicting to our results was Matteo Ceci et al., 2017[20] found that the staining beverages caused significant discolorations for all the tested composite materials. The first exposure to Cola enhanced the subsequent staining with coffee or red wine. Nanohybrid composites reported the lowest color variations.

Studies evaluating the optical properties of Bio HPP material are limited.

Conclusions

Within limitations of this clinical study, the following conclusions could be drawn as follows:

Bio HPP and IPS e.max full coverage restorations revealed excellent surface textureafter one year follow up and the modified PEEK polymer can be successfully used in aesthetic anterior restorations.

Fracture Strength of Two Types of Posterior Occlusal Veneers Made of Hybrid Ceramics with Different Thicknesses

Ahmed S. Abd El Shakour[1], Cherif A. Mohsen[2], Magda I. Ramzy[3]

[1]Assistant Research, Fixed and Removable Prosthodontic Department, National Research Center, [2]Professor, Vice Dean & Chairman of Fixed Prosthodontic department, Faculty of Dentistry, Minia University, [3]Professor, Fixed and Removable Prosthodontic Department, National Research Center

Abstract

Objective: The purpose of this study was to investigate fracture strength of two types of hybrid ceramic posterior occlusal veneers with different thicknesses.

Materials and Method: Eighty natural maxillary molars of comparable size. Standardization of the teeth preparations was accomplished using a diamond saw; teeth were sectioned horizontally, removing all coronal tooth structure 4 mm occlusal to the CEJs leaving exposed dentin centrally and peripheral enamel. Samples were randomly divided into two groups (n=40) based on restorative materials that will be used: computer-milled hybrid ceramic (ENAMIC) and Resin Nano Ceramic (LAVA ULTIMATE). Each group was divided into two subgroups according to the type of preparation (conventional and experimental). The experimental preparation had an additional preparation feature. Within each subgroup, specimens were subdivided into two classes based on restoration thickness (0.3, 0.6 mm). Each class was divided into 2 subclasses for testing the fracture resistance and the microleakage. Specimens were stored in distilled water 37ºC for 7 days. Restorations were adhesively bonded to their respective teeth for measuring fracture.

Result: The fracture strengths (mean ± standard deviation) were 2416 ± 676 and 1777 ± 697, N for Lava Ultimate and Vita Enamic, respectively. Lava Ultimate had significantly higher fracture strength than the Vita Enamic ($p < 0.05$); . No correlation between fracture strengths and failure modes was found within each material. Most specimens (48 out of 60) fractured in the restoration without involving tooth structures.

Conclusions: The fracture strength of ultrathin occlusal veneers made from the novel ceramic hybrid matched the strength of CAD/CAM composite. The highest strength was found with the resin nanoceramic material.

Keywords: *Occlusal Veneers, Lava Ultimate, Vita Enamic.*

Introduction

In the past two years Lava-Ultimate and VITA Enamic were introduced. Physical properties of each material as well as its advantages and disadvantages should be taken into consideration when determining which material is best for a particular tooth[(1)].

Furthermore, the concepts of CAD/CAM systems and conservative tooth preparation seem to be converging[(2)].

New composite and ceramic hybrid materials have been introduced, which can be milled at relatively thin thicknesses to accommodate conservative tooth preparations [(3)]. The CAD/CAM composite is manufactured from a restorative composite material (Z100, 3M ESPE) under optimized process conditions to obtain a high degree of cross-linking[(4)]. Thin occlusal veneers fabricated from composite resin blocks have been shown to have higher fatigue resistance than reinforced ceramics[(5)]. A study showed that the thickness of occlusal veneers made with CAD/CAM composite or resin nanoceramic can be decreased to 0.3 mm without affecting the fracture strength[(6)]. A new CAD/

CAM ceramic hybrid material has been developed by infiltration of a polymer into a porous ceramic network (Vita Enamic). The majority volume of the VITA Enamic block is made of feldspar. The remaining volume of the block is made up of resin[7].

Bond strength is obtained from the load at failure divided by the cross-sectional area of the bonded interface and is referred to as the "nominal" or "average" bond strength values.[8]

Material and Method

Tooth Preparation: Eighty extracted human maxillary molars were collected from out patient hospital of National Research Center and Hospital of Minia University. Teeth were selected so that the mean measurement of the bucco-palatal width between the teeth varied by no more than 2.5%. [9]. Standardized tooth preparations replicating a worn occlusal table were accomplished using a diamond saw (Fig.1). Using a digital caliber to measure 4mm [9] occlusal to CEJ the remaining entire coronal structure was removed perpendicular to the long axis of the tooth. Indexing notches were created on the mesial and distal finish lines with diamond rotary bur*.

Fig 1: Extracted tooth specimen mounted in acrylic base.

Factorial Design: The prepared teeth were then randomly assigned to two groups based on the two restorative materials to be tested:

I. Vita Enamic (Vident, Brea, CA). (VE)

II. 3M Lava Ultimate (3M ESPE). (LU)

Each group was divided into 2 subgroups (n=20) according to the type of preparation either conventional and represent as subgroup 1 or experimental which represent as subgroup 2. The experimental preparation will have an additional preparation feature. Within each subgroup, specimens were subdivided into two classes (n=10) based on restoration thickness (class I 0.3mm thickness) while class II 0.6 mm thickness and stand for it letter (A) & (B) respectively. All teeth were subjected to fracture resistance test.

40 of the selected teeth were randomly chosen and mounted in a custom made gypsum cast made with a centralized hole. The surveying platform of a dental surveyor is used to adjust the parallism of the custom made gypsum cast. A high speed contra angel was attached to the surveying arm with certain angle 70° to create the same finish line (bevel) for all the chosen experimental teeth and a protractor was used to determine this angel.

Scanning of the prepared samples: A standardized occlusal form was created by trimming the cervical structure from an anatomic ready made denture tooth to within 0.3 or 0.6 mm of the central fossa measured by caliber (Fig.2).

Which were positioned on the prepared tooth specimens during the ''occlusion'' scans (Fig.3) using Sirona Inlab MCX5 milling machine (5 axis).

Fig 2: Measuring the central fossa by caliber

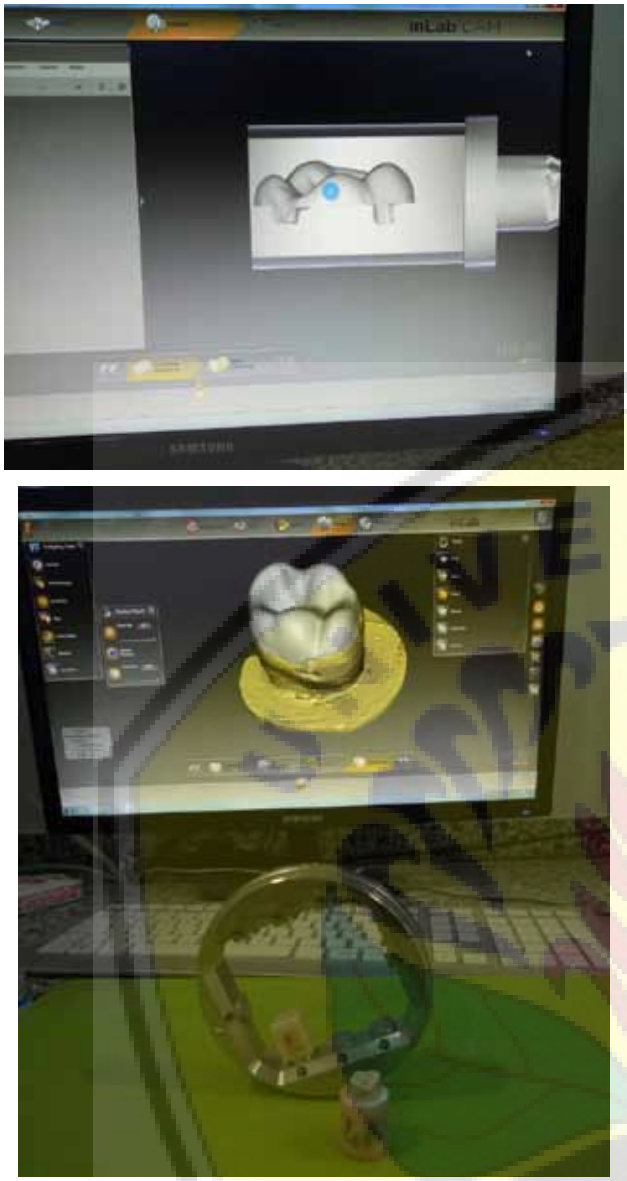

Fig 3: Scans of prepared specimen with and without occlusal form

Restoration Fabrication: Using the virtual design tools within the software. Standard groups of 0.3 mm thickness were constructed from Vita Enamic blocks (VE1A) and Lava Ultimate blocks (LU1A) with a minimal thickness of 0.3 mm, while groups of VE (VE1B) and LU (LU1B) were also designed of 0.6 mm minimal thickness. Groups of VE blocks (VE2A) and LU blocks (LU2B) were designed with modified bevel with minimal thickness of 0.3 mm and groups VE (VE2A) and LU (LU2B) were designed also with modified bevel of 0.6 mm minimal

Finishing and polishing: VE was finished and polished using VITA ENAMIC polishing set technical SofLex polishing discs using the pink polishers of the VITA ENAMIC polishing set at (7,000 – 10,000 rpm) while using water as a coolant. High-gloss polishing with the grey diamond-coated polishers of the VITA ENAMIC Polishing Set (5,000 - 8,000 rpm) with slight pressure was exerted. LU occlusal veneers were finished and polished using Sof-Lex™ discs and diamond polishing paste with silicone impregnated rubber cup.

Cementation: Before the occlusal veneers were cemented, the inner surfaces were air-abraded per manufacturer specifications using 50µm of aluminum oxide at 1.8 bar of pressure, cleaned with alcohol and dried with oil-free pressurized air. The enamel and dentin were etched with 37.5%phosphoric acid for 15sec. The prepared teeth were rinsed and blot-dried. The occlusal veneers were cemented with self-adhesive dual-cure resin cement. A uniform vertical seating pressure of 6 N was applied using a custom-fabricated seating device. All surfaces were light-polymerized for 20sec.The restored teeth were stored in distilled water at room temperature for 7 days prior to testing.

Fracture Strength Testing: All samples were individually mounted on a computer controlled materials testing machine (Model 3345; Instron Industrial Products, Norwood, MA, USA) with a load cell of 5 KN and data were recorded using computer software (Instron® Bluehill Lite Software). Fracture test was done by compressive mode of load applied occlusally using a metallic rod with round tip (5.6 mm diameter) attached to the upper movable compartment of testing machine traveling at cross-head speed of 1mm/min. with tin foil sheet in-between to achieve homogenous stress distribution. The load at failure manifested by an audible crack and confirmed by a sharp drop at load-deflection curve.

Statistical analysis: One-way analysis of variance (ANOVA) followed by Scheffe's post hoc test was used to statistically analyze the difference in failure load among the two materials groups.

After fracture, the specimens were examined under a stereomicroscope with a charge-coupled device (CCD) camera. Statistical analysis will be performed using SPSS® version 20 (Statistical Package for Social Sciences version 20, SPSS Inc, Chicago, IL, USA).

Results

Failure Mode: The mode of failure was categorized as the following:

Mode I, fracture in the restoration only; Mode II, fracture of the restoration and enamel; or Mode III, fracture of the restoration, enamel and dentin. The correlation between the fracture load and mode of failure within each material was tested using Spearman's rank-order correlation.

The fracture strengths were significantly different between the two groups (one-way ANOVA, $p < 0.002$). The LU (resin nanoceramic composite material) occlusal veneer showed significantly higher fracture strengths than the restorations made with VE (Scheffe's post hoc test, significance level 0.05).

Statistical significant difference in fracture strengths was found in occlusal veneers made VE and LU. (Fig.4) shows the three modes of failure. The numbers of specimens for each failure mode and material type are shown in Table (1).

In the 80 specimens, 58 fractured in the veneer material (Mode I) and 8 of these 58 had a complete delamination of the fractured restoration. 12 specimens fractured in the restoration and enamel (Mode II). 10 specimens fractured in the restoration, enamel and dentin (Mode III). Spearman's rank-order correlation coefficient for the bivariate set of data did not show significant correlation between fracture strength and failure modes within each material.

Table 1

Vita Enamic		
	Specimen label	**Maximum Load (N)**
1	Vita Enamic 0.3 E'out preparation	770.69
2	Vita Enamic 0.3 With	890.36
3	Vita Enamic 0.6 E'out preparation	773.57

4	Lava Ultimate 0.6 With	458.32

Fig. 4: Mode I, failure of Restoration; Mode II, failure of Restoration and Enamel; and Mode III, failure of Restoration, Enamel and Dentin.

Initially, descriptive statistics for each group results. One-way ANOVA followed by pair-wise Tukey's post-hoc tests were performed to detect significance between all groups. Student t-test was done between subgroups. Statistical analysis was performed using Graph-Pad InStat statistics software for Windows. P values ≤ 0.05 are statistically significant in all tests.

Ceramic groups as function of preparation designs and thickness after mechanical cyclic loading are summarized in table (2).

Table (2): Fracture resistance (Mean±SD) for both ceramic groups.

Variables		Preparation design			
		Conventional		Experimental	
		0.3 mm	0.6 mm	0.3 mm	0.6 mm
Ceramic group	Vita Enamic	770.69±36.79	773.57±36.93	890.36±42.51	899.55±42.94
	Lava Ultimate	958.2±45.75	1035.67±49.45	1252.68±59.81	458.32±21.88
t-test	P value	0.0006*	<0.0001*	<0.0001*	<0.0001*

Discussion

Preservation of tooth structure is a driving force in restorative dentistry. It is clearly beneficial to keep the pulp alive and prevent endodontic treatment and the need for posts and cores. [9]

As quantified by Edelhoff [2] preparations with deep shoulders and chamfers, as required for complete coverage crowns have been associated with an increase in microleakage and pulpal complications comparing to bonded restorations.

Partial coverage preparations with reduced macro retentive geometry have been reported to remove half the amount of tooth structure compared to a complete coverage. As a result, their range of indications has been increased, including treatment of advanced erosion and stabilization of teeth with cracked tooth syndrome.[10]

The benefits of decreasing retentive features of tooth preparations could be increased by the translational application of principles used in treatment with anterior porcelain laminate veneers, hence the proposal for posterior "occlusal veneers".[11]

Molars of comparable crown size and root dimensions were used, allowing similar dimensions of crowns constructed with CAD/CAM technology and a similar clinical modulus of elasticity.[12]

For samples standardization, a bio generic reference mode in the Cerec software 4.3.1 was used, so that each artificial crown is designed and milled as an exact replica of the unprepared anatomy.

Several factors influence the fracture resistance of all-ceramic restorations, such as microstructure and fatigue of the ceramic material, fabrication technique, the final preparation design and the luting method. [10-12] Tooth preparation was performed according to preparation guidelines stated in the literature. [8]

To imitate rehabilitation in case of severe occlusal abrasion the preparation design was chosen within dentin with a finish line within enamel. [8] Finish line design was a straight beveled finish line to evaluate a possible influence of the marginal preparation design on the fracture resistance.

CAD/CAM technology was chosen due to its ability to control thickness and anatomy of restorations during the fabrication process. It also allowed the standardization of the internal fit of the restoration as well as the mechanical properties of the restorative materials.[6, 9]

In complex multilayered restorations, such as cemented ceramic restorations, several factors contribute to the mechanical behavior of the restoration/tooth system. The intrinsic strength of each component of the system (i.e., tooth, adhesive system, luting cement layer and restoration), the thickness of the restorative material, the ratios of elastic moduli between the restoration material, the luting cement and dentin and finally the quality of the adhesive interface between these layers in terms of bond strength and presence of micro or nano-leakage are all factors that play a role in the behavior of such restorations.[12]

Vita Enamic has resin infiltrated into a sintered ceramic structure. The sintered ceramic structure is porous with a composition similar to feldspar ceramic enriched with aluminum oxide. In our study, neither type of material design ensured superior fracture properties.[13]

LU CAD/CAM Restorative was used because of their modulus of elasticity (12.77 GPa) [13] similar to

that of dentin (approximately 18.5GPa)[14] and they have short laboratory steps. Fatigue resistance was chosen in this study as they are among the critical factors that determine the success and longevity of a restoration [8].

Despite of their many advantages ceramics are brittle materials. Subcritical crack propagation can lead to catastrophic failure [15]. However, it can only show the strength of a restoration immediately after bonding and most likely it shows values of fracture resistance that are not indicative of the long-term success of the restoration. [13] All ceramic restorations can be subjected to fatigue testing from 10,000 cycles to 1,200,000 cycles.[7]

The fact that as the bevel finish line approaches parallelism with the path of insertion of the restoration, the thickness of the space between the bevel finish line and the restoration approaches to minimum value, also bevel finish line helps to reduce the inherent defects in the cementation allowing for better escape of excess cement.

The occlusal veneers made with the novel ceramic hybrid were lower in fracture strength under vertical loading with a resin nanoceramic composite material. The LU is a highly cross-linked particle-reinforced composite, while the VE has resin infiltrated into a sintered ceramic structure [8, 16, 17]. In our study, neither type of material design ensured superior fracture properties.

Within the limitations of this study, the following conclusions were found:

1. Occlusal veneers were found to be a successful mean of restoring erosive posterior teeth.
2. All tested occlusal veneers designs proved to withstand normal and parafunctional masticatory forces.

Ethical Clearance: Study was done in vitro study on samples.

Coping Strategy in Differentianting Levels of Post-Traumatic Growth on Housewives Living With Breast Cancer

Zuardin[1,2],Amran Razak[3], M. Alimin Maidin[4], Muhammad Tamar[5], Ahmad Yani[6]

[1]Public Health Doctoral Student at Hasanuddin University, Makassar, Indonesia, [2]Faculty of Psychology and Health Science, UIN Sunan Ampel Surabaya, Indonesia, [3]Department of Administration and Health Policy, Faculty of Public Health, Hasanuddin University, [4]Department of Hospital Management, Faculty of Public Health, Hasanuddin University, [5]Department of Psychology, Faculty of Medicine, Hasanuddin University, [6]Faculty of Public Health Universitas Muhammadiyah Palu, Indonesia

Abstract

Background: The psychological state of a person will be affected when they are diagnosed with cancer and this condition will actually worsen the physical condition of the patient. However, many breast cancer sufferers are able to face this stressful situation positively and they experience post-traumatic growth. They did a series of coping strategy when they had cancer and some of these strategies were able to influence their post-traumatic growth.

Objective: The current study aims to investigate and to understand how different coping strategy can affect the level of post-traumatic growth of housewives with cancer.

Materials and Method: This study used a descriptive-explorative qualitative approach with eight women with breast cancer completed surveys using the Posttraumatic Growth Inventory (Tedeschi & Calhoun). The coping strategy was obtained using an interview.

Results: The results of the present study indicate that sufferers performed different coping strategies and this affects their level of post-traumatic growth. Respondents with high post-traumatic growth exercise a problem-focused coping i.e. positive reappraisal and emotion-focused coping strategy, i.e. seeking social support when they first learned about the condition of their disease. Respondents who had low post-traumatic growth, on the other hand, did emotional-focused coping strategies, which is avoidance and distancing when they first learned about the condition of their illness. This study also found several factors that influence patients' strategy.

Conclusions: There are differences in the Coping pattern Strategy used by housewives with breast cancer in terms of differences in levels of post-traumatic growth it has. The pattern of coping strategy that is carried out for the first time by housewives with breast cancer could lead them to be in a variety of post-traumatic growth conditions.

Keywords: *Coping Strategy, Post-Traumatic Growth, Breast Cancer.*

Introduction

Cancer is the leading cause of death worldwide in both developed and developing countries(1). However, the burden of cancer is more prevalent in developing countries(2). Research conducted in Malaysian's urban areas on breast cancer patients showed that patients experienced anxiety as much as 31.7% and depression as much as 22.0%. Patients who did not experience adequate financial support usually tend to experience depression(3). Shont explained that a person would automatically experience shock when he found out he

was suffering from a serious health problem, such as when someone diagnosed with breast cancer[4]. This condition is then called as a stressful event[5].

The current study aims to investigate and to understand how different coping strategy can affect the level of post-traumatic growth of housewives with cancer.

Materials and Method

This study used qualitative method with descriptive-explorative design. The design was considered in accordance with this study which aims not only to describe the form of coping strategy used by housewives with breast cancer with different levels of post-traumatic growth, but also to explore what factors cause these differences.

There aretwo types of analysis unit used, those arecoping strategy and post-traumatic growth. a) Post-Traumatic Growth is a condition where housewives with breast cancer become more appreciative of the life lived, more recognizes one's ability to be more familiar with people in their environment, more diligent in worshiping and other religious activities and living their life in new ways, after knowing their status of breast cancer is obtained using the Post-Traumatic Growth Scale from Tedeschi and Calhoun [6]. Coping strategy is an effort made by housewives with breast cancer after being diagnosed with breast cancer in order to reduce the pressure experienced [7].

The population in this study was housewives with breast cancer who underwent treatment at the Hasanuddin University Teaching Hospital Makassar. The sample was selected using a purposive sampling technique with certain considerations. The characteristics of the sample are as follows: 1) Residing in the city of Makassar, 2) Following treatment at Hasanuddin University Teaching Hospital Makassar, 3) Willing to be interviewed.

The data in this study were collected through scaling and interviewing the subject. First, the researcher measured the levels of post-traumatic growth by using the Post Traumatic Growth Inventory (PTGI) from Tedeschi and Calhoun [6]. This scale has previously been translated into Indonesian and by testing the content validity of three experts and the readability test. After obtaining post-traumatic growth level data, interviews then were conducted on the subject in the form of semi-structured. In this interview, the researcher prepared an interview guide based on the Coping Strategy theory of Lazarus and Folkman [8].

Results

This study involved 8 respondents of housewives with breast cancer, two people aged 31 years old, two people aged 35 years old, two people aged 36 years old, one person aged 38 years old and one person aged 39 years old.

Based on the background of their tribes, it can be seen that the respondents of this study consisted of 4 people from Bugis tribe and 4 people from Makassar tribe. In terms oftheir religious profiles, all respondents embraced Islam. As for the first year diagnosed with breast cancer as many as two respondents experienced it in 2007, while 6 others each experienced it in 2008, 2010, 2011, 2013, 2016 and 2018. For more details, an explanation regarding the personal profiles of all respondents can be seen in table 1.

Table 1: General Characteristics of Respondents

No	Name	Age	Occupation	Religion	Tribe	Year Diagnosed
1	VR	31	Housewife	Islam	Makassar	2007
2	ER	31	Housewife	Islam	Makassar	2007
3	YS	35	Housewife	Islam	Makassar	2008
4	PR	35	Housewife	Islam	Makassar	2010
5	LM	36	Housewife	Islam	Bugis	2011
6	UM	36	Housewife	Islam	Bugis	2013
7	AR	38	Housewife	Islam	Bugis	2016
8	YL	39	Housewife	Islam	Bugis	2018

This study required groups of respondents with varying levels of post-traumatic growth through purposive sampling technique using the assistance of the scale of post-traumatic growth from Tadeschi and Calhoun given to each respondent. From this, the categories of High (H) and Low (L) with N = 2 were obtained for each of these categories, then further interviews will be carried out in order to collect qualitative data in accordance with the formulation of the problems of this study. So that, for the next discussion, the sample in this qualitative study were 4 people. More details can be seen in table 2

Table 2: Charateristics of Respondents based on Post-Traumatic Growth Levels

Category	Code of Respondent	Score of Post Traumatic Growth
High	HA	105
	HB	98
Low	LA	63
	LB	67

Results Description of Respondents HA and HB

Coming from a family background of the police, she explained that since childhood she had been taught to be a strong and not whiny person [9]. This can be seen from the statement as follows:

"Perhaps, basically if there is a problem, I will not prolong it because I am used to it since my childhood, I am used to being trained from my previous family and my father, my mother had died when I was child…" (153-155, HA)

"It might be because I am from police family, my father is policeman, my elder brothers were policemen, the three are policemen, so that perhaps I am educated not to be whiny…" (192-194, HA)

When HA was diagnosed with breast cancer, trying to do self control,it madeher did not get panic when she got diagnosed. In fact, she tried to find a drug that must be consumed at that time. The effort she made was then called planful problem solving [10, 22], as stated in the following:

"I am not surprised, just let it flow (while laughing). He was surprised, maybe he waited how my response, I rampaged or cried but I did nothing," just response like that'. "so, how about it, Sir?" (1011-1014 HB)

".....oh yes, Sir, I still call you with Sir …, yes, Sir. So, what should I do next for the treatment?" (62-64 HB).

HA explained what she understood at the time to her biological family, she also tried to give understanding to her family so there would be no misunderstanding about her condition at that time. Even this can be called an attempt to seek social support coping which is one type of emotional focused coping where individuals seek social support for themselves who are in a stressful condition so as to relieve the burden they have [11], as stated in the following HA:

"At what time… I beg for permission, uh, with my family, with my parents-in-law especially, what information I have received I also tell them so they know too….."*(173-175, HA)*

"I ask with my friends here to give the explanation with my family, please to tell them that this disease is not contagious," (368-371, HA).

Results Description of Respondent LA and LB: When LB was first diagnosed, she felt very sad, disappointed in herself and did avoidance and anger at God for the fate she received from cancer [12, 18]. But she cannot do anything. This can be seen from the following quote:

"*At first I felt it, I must be angry with God, why did God give my fate this disease....." (331-332 LB)"*

She was afraid to undergo treatment that must be received for life, making her prefer to use efforts to distance by thinking first or in other words delaying treatment [13, 19, 21]. This can be seen in the following quote:

"At the time, I have had the disease, I was advised to take medicine, or chemotherapy, but I had not done chemotherapy yet. Yeah because I heard it has a lot of the side effects, so I was scared."(1024-1026 LA).

Discussion

Based on the results that have been obtained by comparing groups of high and low levels of post-traumatic growth, then it is known that groups of respondents who are at a high level of post-traumatic growth are more likely to develop problem focused coping efforts. In addition, high groups are also known to develop emotional-focused coping efforts in the form of seeking social support and positive reappraisal. These findings

are in line with the research conducted by Ramos and Leal [14]who stated that the problem focused coping and emotional-focused coping strategies both have positive correlations to the high levels of post-traumatic growth a person has. It is also found that coping strategies are positive, in this case positive reappraisal coping and seeking social suppport coping are also significant predictors in influencing post-traumatic growth levels.

In the high group, it can also be seen that the two respondents from the high group were kind to God with the fate given to them, because they had the presumption that they were being given time by God to better improve themselves in order to become a better person. The strategy carried out by these high respondent groups can be categorized as a form of religious coping in the form of a wise assessment of God. Research conducted by Chan and Rhodes [15] found the contribution of religious coping in order to increase the level of a person's post-Traumatic Growth. So it is not surprising to see HA and HB at high levels of post-traumatic growth.

Avoidance strategies that tend to be carried out by groups of respondents with low levels of post-traumatic growth are supported by research from Sahin, Z. A et al (16)who stated that the form of coping strategy that is highly correlated with low levels of Post-Traumatic Growth is a form of avoidance. Avoidance Coping as a form of someone's rejection of her condition is indeed inversely proportional to the concept of Post-Traumatic Growth.

This is seen in what happened to the Low Post Traumatic Growth group. It is known that the respondents were very closed to the status of the disease because they were worried that they would get rejection from family and society [17, 20]. When it is compared to the respondents from the high Post-Traumatic group, there was no apparent internalization of the cancer stigma in them. Even though both of them had felt discrimination over their status as cancer sufferers, they did not internalize this matter and instead preferred to deny the stigma circulating in the society with confidence to appear in front of many people to socialize it.

Limitations: Respondents for this study, although in terms of population in large numbers, but many breast cancer survivors are not willing to conduct in-depth interviews due to the status of their illness.Therefore, there are not many respondents involved. This study used a qualitative approach, so that it cannot be known about the correlation or influence of each form of coping strategy or the factors that influence it to the levels of post-traumatic growth and aspects of PTG on housewives with breast cancer.

Conclusions

There are differences in the Coping pattern Strategy used by housewives with breast cancer in terms of differences in levels of post-traumatic growth it has. The pattern of coping strategy that is carried out for the first time by housewives with breast cancer could lead themto be in a variety of post-traumatic growth conditions.

The group of housewives with breast cancer that apply the problem focused coping effort for the first time in facing her condition as an individual diagnosed with breast cancer was found to be better able to deliver it to a high post-traumatic growth condition. In addition, the form of positive reappraisal coping and seeking social support coping that has been developed by housewives with breast cancer can lead her to make peace with herself so that she has high post-traumatic growth after being diagnosed with breast cancer.

The group of housewives with breast cancer are more likely to apply emotional focused coping strategies, especially in the form of avoidance and distancing coping when they first find out their condition as cancer sufferers, it seems more difficult to deliver themselves to post-traumatic growth conditions, so they are still at post Low -traumatic growth.

Competing Interests: The author(s) declared no potential conflict of interests concerning the research, authorship and publication of this article.

Prevalence and Factors Associated with Waterpipe Smoking among Private University Students in Erbil City

Parzheen M. Ratha[1], Samir M. Othman[2], Nazar A. Mahmood[3], Namir G. Al-Tawil[2], Tariq Salman Al-Hadithi[2]

[1]Erbil Directorate of Health, KBMS in Community Medicine, [2]Department of Community Medicine, College of Medicine, Hawler Medical University-Erbil, [3]Department of Community Health, College of Nursing, Kirkuk University, Iraq

Abstract

Background and Aims: Waterpipe tobacco smoking is increasing in popularity and becoming more prevalent among university students in the last decade. The main objective of this study was to find out the prevalence of waterpipe smoking among students of two private universities. Next to find out the association between waterpipe smoking with various socio-demographic characteristics of the study sample, and to detect a possible association of waterpipe smoking with various risk factors.

Method: A cross-sectional study was carried out from the 1st of Jan. 2016 to the 31st of Dec. 2016, involving 2000 students from two private universities(Ishik and Cihan) in Erbil city- Kurdistan Region, selected by multistage cluster sampling technique. A modified self-administered questionnaire was used for the collection of information. The statistical package for social sciences (SPSS) version 21 was used for data entry and analysis.

Results: The overall prevalence of ever waterpipe smoking and current waterpipe smoking was 38.9% and 26.9% respectively. The prevalence of current waterpipe smoking was significantly higher among males (42.3%) than females (8.6%), and 56.0% of smokers started smoking waterpipe at age more than 18 years old. Residency, marital status, house ownership, and monthly family income had no significant effect on the prevalence of waterpipe smoking. Binary logistic regression analysis revealed that male gender, parents smoking, siblings smoking, friend smoking waterpipe was positively associated with waterpipe smoking.

Conclusion: The prevalence of waterpipe smoking was relatively high among university students, especially among male gender. The prevalence of waterpipe smoking is higher when a family member or a friend is a waterpipe smoker; the rate is also increasing with the presence of cigarette smoking habit.

Introduction

Tobacco smoking continues to be the number one preventable cause of morbidity and mortality, contributing to over five million deaths every year[1].The World Health Organization (WHO) estimates that by the year 2030, more than 8 million deaths will be attributable to tobacco smoking, with the added burden of tobacco-specific morbidities targeting the cardiovascular and pulmonary systems. In the last two decades, the global epidemiological gradient of tobacco smoking began to change with new and alarming trends in waterpipe tobacco smoking[2].

Waterpipe smoking is a growing phenomenon associated with substantial toxicant exposure, numerous health risks, and development of dependence in a considerable proportion of users[3].Worldwide data about waterpipe use were collected, and the trends were quite alarming[4],especially in the Eastern Mediterranean Region (which includes Middle Eastern and North African countries) which has the highest prevalence of waterpipe use in the world[5].

In the Middle East, waterpipe smoking has quickly replaced cigarettes as the most popular method of tobacco use among youth, and in several other parts of

the world, it is becoming second only to cigarettes. A multi-country study involving representative samples of 13-15years old school children in several countries in the Arabian Peninsula (Bahrain, Oman, Qatar, United Arab Emirates, Kuwait, Saudi Arabia, and Yemen) showed a prevalence of waterpipe smoking from 9% to 15%[4].

According to the researchers' observation, waterpipe tobacco smoking is now increasing in popularity especially among young adults in Iraq including the Kurdistan Region. This spread could be related to limited knowledge of the negative health effects of waterpipe smoking, and to a large number of coffee shops and restaurants serving waterpipe. Furthermore, there is little published data about this subject in the Kurdistan region. This provided the impetus for the researchers to carry out a study on the prevalence, association between socio-demographic characteristics and other epidemiological variables with waterpipe smoking and awareness about waterpipe smoking and its effect on the health among private university (Ishik and Cihan) students in Erbil city.

Method

Design and sampling technique: A descriptive cross-sectional study was carried out from the 12th of January 2016 to the 12th of April 2016, involving two private university students of Iraqi nationality.

Out of a total of six private universities in Erbil city[6],two universities (Ishic and Cihan universities) had been chosen randomly by using simple random sampling method, for theacademic year 2015-2016. The total number of students in Ishikand Cihan universities was 2635 and 6339 respectively.

The EPI info (version 7) computer program (a free program created by the Centers for Disease Control, USA) was used to calculate the sample size. The following information was entered into the program:

Expected population size: 10000, the estimated prevalence of waterpipe: 20%[7], absoluteprecisions: 2.5%, Confidence level: 95%, Design effect: 2, accordingly, the estimated sample size was 1790 students; however, 2000 students have been included in the study, considering nonresponse rate. Cluster sampling technique was used to select the students. The number of students of each sample (cluster) was proportional to the size of the total number of students of each faculty. One to two classes from each department were randomly selected and invited to participatein the study in order to collect are presentative sample of students.

Instrumentation: Data were collected by using a modified, self-administered questionnaire that was designed by the researchers[8, 9]. The questionnaire was translated into Kurdish and Arabic languages by the researchers, knowing that the mother tongue of two of the researchers is Arabic, and it was Kurdish for the other two. It is worth to mention that the teaching language of the medical schools in Iraq is English and all the researchers had studied in the Iraqi universities. The questionnaire was composed of three parts. The first part included socio-demographic characteristics of the participants, such as gender, marital status, living place, residency, socio-economic status, etc….

The second part included other epidemiological variables that are associated with waterpipe smoking and pattern of smoking; and the third part included questions related to knowledge and awareness about waterpipe smoking and its effect on the health (composed of 15 questions which were answered by yes, no or do not know). The content validity of the questionnaire was assessed by a group of experts in the community medicine department at the college of medicine / Hawler Medical University.

At each class, the participants were invited to complete the questionnaire at the end of the session after explaining the purpose of the study for them. Permission was obtained from the participants to take 20-25 minutes to complete the questionnaire. Participants were also informed not to discuss the questions with each other. If they had any queries, they were encouraged to ask the researcher.

Anyone who had ever tried waterpipe, regardless of the current smoking status, was defined as 'ever waterpipe smoker'[10]. Current waterpipe smoker was defined as anyone who smokes waterpipe currently or during the last 30 days, 'Occasional smokers' were defined as those using waterpipe less than or equal to once a month, and 'frequent smokers'were defined as those using waterpipe more than once a month[10, 11].

The crowding index was measured by dividing the number of persons in the family by number of rooms, except the kitchen and bathroom.

A 15 units scoring system (scale) was used to assess the level of knowledge. Then the 15 units' scale was

divided into three equal categories as follows: 0-5 as poor knowledge, 6-10 as moderate knowledge and 11-15 as good knowledge.

Prior to the start of the (main) study, 22 students of the preliminary stage of Ishik University were included in a pilot study in order to finalize the questionnaire and to assess its clarity, in addition to identifying any problem in the process of data collection, and calculating the time needed. Those students were not included in the main study.

Data Analysis: The Statistical Package for Social Sciences (SPSS) version 21 was used for data entry and data analysis. Both descriptive and analytic approaches were used for analysis. Frequencies (and proportions) were calculated in order to summarize the categorical variables, and the means± SDs were calculated in order to summarize continuous variables. Chi-square test was used to determine the association between categorical variables. Factors found to be significantly associated (by Chi-square test) with waterpipe smoking had been entered into a binary logistic regression model in order to show the independent effect of each factor on the waterpipe smoking. A p-value of ≤ 0.05 was regarded as statistically significant.

Results

Socio-demographic characteristics of participants: Two thousand students participated in the study, and none of them refused to participate, but because of the extensive missing of data, 20 questionnaires had been discarded. Accordingly, the analysis was done on 1980 questionnaires.

The mean age ± SD of the study sample was 23.19 ± 4.5 years. Nearly half (45.7%) of the sample aged 20-24 years, 27.4% aged less than 20 years, and only 3.3% aged ≥35 years (Table 1). The table shows that 54.2% of the sample were males, and the male: female ratio was 1.18:1. It shows also that 84.4% of participants were singles, 87.2% were Kurds,and 87.1% were living at home with their parents while 12.9% were living in the dormitory. Regarding the monthly family income, 58% mentioned that it was enough. Details of socio-demographic characteristics are shown in Table 1.

Prevalence of waterpipe smoking by socio-demographic characteristics of participants: Table 2 shows that the overall prevalence of current waterpipe smoking among the study sample was 26.9% (532 out of 1980), while the prevalence rate of ever waterpipe smoking was 38.9% (772 out of 1980). The prevalence of current waterpipe smoking was significantly four times higher among males 42.3% than females 8.6% ($p < 0.001$). Regarding the age groups,the prevalence of waterpipe smoking was highest among students aged 25-29 years old and lowest among those aged more than 35 years ($P<0.001$).

The table shows that the prevalence of waterpipe smoking was slightly higher among those living in the dormitory (28.9%) than those living in the parental home (26.6%), with no significant association($P=0.431$). This study also revealed no significant association between waterpipe smoking and several factors like residency ($P=0.990$), marital status ($P=0.886$),ethnicity ($P=0.533$), crowding index ($P=0.511$) and monthly family income ($P=0.312$) (Table 2).

Pattern and behavior of waterpipe smoking: Table 3 shows that more than half of the smokers (56.0%) started smoking waterpipe at age > 18 years. The majority of the smokers (90.6%) had been smoking waterpipe for years while 1.5% of them had been smoking for weeks. The frequent waterpipe smokers represent 81.2%of the sample, and about 56.9%of them smoked weekly and only 18.8% of the smokers smoked occasionally. More than three-quarters of them were smoking with their friends and 4.7%used to smoke alone. 69.4% of them smoke at cafés and 7.1% of them smoke at home. More than half of the participants (58.9%) thought that they were smoking waterpipe just for pleasure and 6.2% of them thought that the cause of smoking is that it is fashionable while the cause of smoking waterpipe in 4.1% of smokers was an imitation.

Association between certain risk factors and current waterpipe smoking: Table 4 shows that there is a statistically significant association between individuals smokingwaterpipe with a smoking history of father, mother, sibling, and friends. A statistically significant association was also found between waterpipe smoking and cigarette smoking (currently or ex-smoker) ($p < 0.001$).

Association between knowledge score with waterpipe smoking

Table 5 presents the knowledge levels of participants toward the harmful effects of waterpipe on human health. It shows that 42.7% of the non-smokers had moderate knowledge, and 34.4% had good knowledge, compared

with 39.9% and 31.0% respectively among the current smokers (p = 0.013).

Association between knowledge score with gender: Table 6 shows no significant association between gender and the level of knowledge (p = 0.484).

Factors related to waterpipe smoking by using binary logistic regression analyses: Binary logistic regression analysis of variables associated with waterpipe smoking revealed that male gender, age (< 35 years), a smoking father, a smoking mother,smoking siblings, friends smoking waterpipe, current smoking of cigarettes, ex-smoking, and poor knowledge, are regarded as predictive factors of waterpipe smoking (Table 7).

Discussion

This is the first study that had been carried out among university students in Erbil city, to find out the prevalence of waterpipe smoking and to study the factors that are associated with smoking.

Prevalence of waterpipe smoking: The current study revealed that the overall prevalence of ever waterpipe smoking and the prevalence of current waterpipe smoking among both private universities were 38.9% and 26.9% respectively. The finding of the current prevalence of waterpipe smoking is nearly similar to waterpipe smoking prevalence among university students in Lebanon (28%) [7], and to reported prevalence in monitoring the future (MTF) study in the US (25.7%)[12]. While less than that reported in studies done in Turkey[13] and Iran[10] (32.7% and 40.3% respectively).

On the other hand, the prevalence rate of waterpipe smoking in our study is higher than that reported in a study done among Malaysian university students(20%)[8], and higher than what was reported in the North Carolinastudy of the USA (17%)[14].

This high prevalence of waterpipe smoking in our study might be due to the sudden increase in numbers of cafés serving waterpipe in Erbil city and to the presence of a large number of tourists, refugees, and foreigners in our region coming from countries that waterpipe

smoking is already an established cultural habit.

Association between socio-demographic characteristics and waterpipesmoking

Gender and waterpipe smoking: The prevalence of waterpipe smoking was significantly higher among males (42.3%) than females (8.6%). This finding is in agreement with studies done in Turkey[13] (41.6% in male students versus 20.2% in female students) and in Iran[15](28.7% in males versus 11.5% in females). On the other hand, a study done in Jordan showed a higher prevalence rate of waterpipe smoking among females(88.6%) than among males (36.6%)[9]. This finding is due to the fact that in most of the Eastern Mediterranean countries, waterpipe has been used traditionally for centuries, and among women, it is accepted as a less shameful event compared to cigarette smoking[13, 16].

While in Kurdistan region this difference in gender might be due to culture,and religion where boys have more freedom than girls to spend their time outside homes and to go to cafés, hence became more liable to be affected by this social behavior.

Age and waterpipe smoking: The study showed that the highest prevalence of waterpipe smoking was in the age group 25-29 years. Similarly, the prevalence of waterpipe smoking was highest among this age group of students at Mount Kenya University, Kigali city Rwanda[17]. In the USA, waterpipe smoking peaks among 19-21 years old compared to other age groups[18,19]. This might be due to the effect of the social culture of neighboring countries,but the highest prevalence in our study was in (25-29) age group, this might be to in this ages youth were not employed by governorate after completing studying in universities and most of them spending their time by going to cafes accompanied their friends.

Socio-economic state/monthly family income and waterpipe smoking: The prevalence of waterpipe smoking has no significant association with family income, although it was higher among the high-income families. This is in agreement with a study done in Turkey in which the economic status of the family has no significant effect on the prevalence rate of waterpipe smoking[13]. In contrast to studies done in Pakistan[20], Great Britain[5] and USA[21], the highest percentage of waterpipe smoking occurred among the high socioeconomic status persons. In Erbil city, there is a big discrepancy in the cost of a waterpipe session, which is cheap if smoked at home, and costly if smoked in a prestigious café. This might explain the mentioned non-significant association.

Residency and waterpipe smoking: The study revealed that residency (living in the home vs. dormitory/ residing in the ruralvs. urban area)was not associated with the prevalence of waterpipe smoking. This is in agreement with a study done in Turkey that residencies of students have no significant effect on the prevalence rate[13].

Behaviors of waterpipe smoking

Age of starting and duration of waterpipe smoking: The study revealed that most of the smokers had been smoking for years. Also the study showed that more than half of the smokers started smoking waterpipe at age more than 18 years old while in Iran,a study revealed thatthe smokers have started waterpipe smoking in their mid-teens[10], this might be due to that our youth after the age of 18 years become more independent in making decisions about their social behaviors that might be affected by mixing with friends in the universities and cafes inside Iraq, or affected by the culture of the nearby countries where smoking waterpipe is a normal habit.

The pattern of waterpipe smoking: The study showed that 32.4% of participants were daily waterpipe smokers and 56.9% were weekly smokers. In contrast to a study done in Bahrain, in which 61% of the participants smoked waterpipe daily, with a further 29% using it weekly[22]. Also, the study revealed that about half of the weekly smokers used to smoke waterpipe once / week which is slightly more than that reported in Jordan where 46.7% smoked waterpipe once/week[9], but much more than that of a Turkey study which shows that only 18.5% smoked once/week[13]. Also,the study revealed that 81.2% were frequent smokers and 18.8% were occasional smokers. In Iran, 44.7% were frequent smokers and 55.3% were occasional smokers[10].

With whom smokes waterpipe: The study revealed that more than two thirds(77.7%) of smokers smoked waterpipe with their friends, this is in agreement with a study done in Turkey in which most of the students were smoking waterpipe with their friends, and collective use was common[13]. Also in other studies,many waterpipe smokers practice the habit in the company of friends and family and treat it as a central element of social and family gatherings[23]. The reason behind that might be attributed to the fact that the new smokers are affected by their friends who had been already smoking a waterpipe.

Effect of family members and friends on initiating waterpipe smoking: The study showed that there was a significant relationship between the effect of family members and friends on smoking waterpipe. The presence of a family member who smokes waterpipe increases the probability of smoking by 3.9 times, and the presence of a friend who smokes waterpipe increases the probability by 7.6 times. In Turkey, this value was found to be approximately five times for family members and three times for friends[20],and also in a study performed in the USA, it was found that the presence of a family member smoking waterpipe increases the smoking probability in other individuals by 6.3 times[24]. This might be due to the fact that; when a family member smokes waterpipe, he/she.

Reasons for waterpipe smoking: Will encourage the other members to smoke, and hence it will become a socially accepted behavior.

Place of waterpipe smoking: The study showed that more than two thirds (69.4%) of waterpipe smokers preferred smoking in cafés;this is in agreement to studies done in Erbil city, Iraq[25, 26] and Turkey[11] in which the preferred places to smoke were cafés. This is because cafes are the place of gathering friends and sharing of waterpipe among themselves.

The study showed that more than half of the smokers' smoke waterpipe for pleasure, this is in agreement to a study in Turkey where 72.4% of smoking waterpipe was for enjoyment[13].In Iran, the majority (75.5%)of the current waterpipe smokers indicated that the fun and social aspect of waterpipe use was the main motivating factors for them to continue smoking[10]. While in Bahrain, 58% of participants justified the increase in waterpipe smoking to the boredom[22].

Association between waterpipe and cigarette smoking: The most identified associated behavior for waterpipe smoking is cigarette smoking. Many studies from around the world have documented the salience of cigarette smoking among waterpipe smokers, and cigarette smoking has been shown to be a major predictor of waterpipe smoking among youth[4, 27]The same finding was obtained in the current study which showed that 65.2% and 39.9% of current waterpipe smokers significantly associated with current cigarette and Ex-cigarette smokers respectively. This is in agreement withthe finding of another study in which the prevalence of waterpipe smoking was nine times greater in students with the habit of cigarette smoking[13]. A following up study in Jordan revealed that current cigarette smokers at baseline were twice as likely to become waterpipe smokers after 2 years compared to non-smokers, however, the reverse also was true[28].A study of the USA (Monitoring the Future survey) showed that waterpipe use among high school seniors was associated with current and former cigarettes smoking[4]. By these results, we can say that cigarette smoking is a gateway for waterpipe smoking and the reverse is true.

Awareness and knowledge of students about waterpipe smoking and its effect on health: This study revealed that 32.0% of waterpipe smokers had poor knowledge about the harmful effect of waterpipe on health which is less than what was reported in studies done in Erbil city (56%)[25], Iran[10], Jordan[9],and Malaysia[8] where the majority of the participants believed that waterpipe smoking is harmful to health. On the other hand, a study from Egypt revealed that 74% of female students believed that waterpipe smoking is less harmful than cigarette smoking[29]. Although in general, university students' awareness washigher but relatively low regarding the negative consequences of waterpipe smoking that might be the cause of high prevalence among students.

Gender comparison in Ishik and Cihan universities for waterpipe smoking: The study revealed that the prevalence of waterpipe smoking among males was higher than females in both Ishik and Cihan universities (43.7% vs 8.9% and 41.7% vs 8.5% respectively). On the other hand, waterpipe smoking was significantly associated with male gender in both universities; except for the faculty of education.

Conclusion

The prevalence of waterpipe smoking is relatively high among university students, especially among male gender. The prevalence rate of waterpipe smoking is increasing when a family member or a friend is a waterpipe smoker; the rate is also increasing with the presence of cigarette smoking habit. Awareness and knowledge about consequences of waterpipe smoking on health among waterpipe smokers are relatively poor.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: The study protocol was approved by the research ethics committee of the Kurdistan Board of Medical Specialties, written permission was obtained from the Deans of both private universities. The verbal informed consent was obtained from each participant and the anonymity of the participants' names was ensured. All selected participants were cooperative and agreed to participate in the study.

Four Screening Methods to Determine *Pediococcus Acidilactici* Efficacy Against Two Biofilm-Producing Pathogenic Bacteria

Zainab Owaid Shatti[1], Basam Basim Mohammed[1], Yusra M.B. Mohsin[1], Wissam Adnan Dari[1]

[1]*Department of Biology, College of Science, Mustansiriyah University, Baghdad, Iraq*

Abstract

A biofilm is a thin layer of microbial slime & related to many infections so is considered the main virulence factors and *Pediococcus acidilactici*has a well-known positive effect on pathogenic bacteria. Therefore this study aimed at applying the antibacterial and antibiofilm effects of *Pediococcus acidilactici* (Cell-Free Supernatant and culture) against the growth of two common pathogens *Staphylococcus aureus* (skin infections source) and *Serratia marcescens* (Urinary tract infection source) by four method Co- culture, plug & disk method andMicrotiter plate assay, the CFS & culture of *Pediococcus acidilactici* showed a good antibacterial activity against both pathogens. disk method was the least effective among them. Both pathogens were screened for biofilm production by using Congo-Red agarmethod and the results were both pathogens had the abilityto produce biofilm, but this ability decreased obviously when treated with CFS concentrated (CFSc) and CFS not concentrated (CFSnc) but CFSc displayed higher inhibition ratio recorded by system reader in optical density (OD) ELISA system. This work indicate that the use of this*Pediococcus acidilactici*could contribute to impair both pathogens in growth and biofilm formation.

Keywords: *Pediococcus acidilactici, concentrated cell-free supernatant, Co-culture method, Plug method, disk method & ELISA system.*

Introduction

Lactic acid bacteria (LAB)are reported to produce antimicrobial substances ; including many of generaarea group of Gram- positive, anaerobic bacteria[1]. The general description of bacteria included in the group is cocci or rods, no spore forming and the acids are a major end products for fermentation of carbohydrates[2]. *Pediococcus* is a genus of LAB is usually homofermentative anaerobic or microerophilic, it is typically chemoorganotrophic [3] and recognized as probiotics (probiotics are live microorganisms that improving the intestinal microbial balance) [(4,5)]. Is one of this genus that is well known to have a good effect on the improvement of human health [6].Biofilm is made of bacteria, according to[(7,8)] defined as a sticky, polysaccharides produced from bacterial cells that attachment on surfaces such as on aqueous environments by communities[(7,8)]. *Serratia marcescensis* an opportunistic human pathogen causing many infections by secreting several of virulence factors capable of damaging human cells and tissues like enzymes productions [9], or biofilm maturation [7]. *Staphylococcus aureus* also is an opportunistic pathogen responsible for significant health problems in humans [10]. *S. aureus* survival in the environment is at least in part due to its production of biofilm . Biofilm formation is regulated by expression of polysaccharide intra cellular adhesion (PIA), which mediates cell to cell adhesion[11]. Because of the importance of LAB application against many types of pathogenic bacteria [(12,13,14, 15,16)], and biofilm production by these bacteria, this study was objected to determine the effectiveness of *pediococcus acidilactici* against the growth of two pathogenic bacteria and inhibit their biofilm production, So this *pediococcus acidilactici* if prove its benefit, would be able to use it as antibiotic alternative agent (natural agent).

Materials and Method

1. **Pediococcus acidilactici isolate:** *Pediococcus acidilactici* that isolated from cow milk was obtained from Biology department/Science College/ Mustansiriyia University/Baghdad/Iraq. This isolate was identified again with VITEK®2 GP ID card.

2. **Cell Free Supernatant of Pediococcus acidilactici (CFS) preparation:** CFS of *P. acidilactici* used in this study was prepared according to [17] as follows: *P. acidilactici* was incubated in MRS (Man-Rogosa-Sharp) broth and incubated for 72 hrs under anaerobic condition at temperature 37°C., the broth then centrifuged for 10 min at 10.000 rpm. The supernatants were sterilized by filtration through (0.22 µm) Millipore filter paper. CFS was used for determination the inhibitory activity of *P. acidilactici* against growth of pathogenic bacteria.

3. **Concentrate the Cell Free Supernatant:** To get high activity of inhibition, CFS was concentrated by drying it in oven for (4-8) hrs. until reach to required concentration to obtain once concentration and used for following test [1].

4. **Staphylococcus aureus and Serratia isolates:** Isolates of *S. aureus* isolated from skin infections and *Serratia* isolated from urinary tract infections, submitted to biochemical reactions and identified according to[18].

5. **Biofilm production ability test of pathogenic bacteria:** Biofilm production ability was tested by Congo red agar method [19], that composed of brain heart infusion agar 37 (w/v), Congo red dye supplemented with 0.8 (w/v), and sucrose 5 (w/v). Congo red medium was autoclaved for 15 minutes at 121◦C. Then plates were inoculated with test organism and incubated at 37◦C for 24 to 48 hours. The biofilm producer bacteria isolates formed black or brown colonies.

6. **Determination of the antibacterial activity of Pediococcus acidilactici against pathogenic bacteria growth was investigated by the following method:**

   (A) Co-culture method: In Co-culture method, *P. acidilactici* culture MRS was grown in nutrient broth to prepare CFS, then added CFS to nutrient broth with different ratio **(1:1, 1.5:0.5, 1.75:0.25)** *P. acidilactici* culture (Nutrient broth : CFS of culture), Co-cultures and control (MRS broth without CFS) after that each of them were incubated with 50 µm (1×10^8) cell/ml from test bacteria (*Staphylococcus* and *Serratia*)separately, then incubated at 37˚C for 24 h., diluted **(10^1- 10^{10}),** last dilution cultured on solid nutrient agar to count and evaluate the inhibition activity by the following equation:

   R (%) = [(A-B) / A] × 100

   R : Inhibition rate.

   A: Control medium colonies number.

   B: Colonies number from treated with CFS.

   This method was done according to[20].

   (B) Plug method: In this method, *P. acidilactici* cultured on MRS agar for three days, in every day an agar-plot is cut aseptically with a sterile cork borer and deposited on nutrient agar plates cultured with pathogenic bacteria separately. Antibacterial activity of *P. acidilactici* culture was measured by measure the inhibition zone around the agar-plot by mm [21].

   (C) Disk method: Disks from filter paper (0.22) µm were prepared, sterilized and submerged with *P. acidilactici* broth culture for 10-15 min, then lift with sterile forceps and put on nutrient agar plated cultured with pathogenic bacteria separately, incubated at 37˚C for (24-48) hrs. The inhibition activity was measured by measure inhibition zone around the disk by mm. This method was detailed in [22].

7. **A quantitative estimate of Pediococcus acidilactici effect against biofilm-producing pathogenic bacteria by OD:** Antibacterial activity of *P. acidilactici* CFS included concentrated CFS and non-concentrated against biofilm production of test bacteria was studied by using flat bottomed micro titration plates, the wells were filled as following:

   1. The first well was filled with (180) µl (brain heart infusion broth) included 2 % sucrose and (20) µl test bacteria culture separately, this was considered control treatment for test.
   2. Second well was filled with (100) µl of not concentrated (CFS) and (100) µl brain heart infusion broth added 2% sucrose and included test bacteria culture separately.
   3. Thired well was filled with (100) µl of concentrated CFS and (100) µl of brain heart infusion added (2%) sucrose that inoculated with test bacteria separately.

The plate was covered with Para film, incubated with 37 ˚C for 24 hrs. After that all plate contents were neglected and washed with distilled water left to dry in

room temperature for (15) min. (200) µl from crystal violate dye to wells, left for (20) min. Wells were washed more than once with distilled water, also left to dry in room temperature for (15) min. (200) µl of ethyl alcohol with (95%) concentration was added for each well. The optical density was read with 630 n. using ELISA Reader systems. The inhibition ratio was tested and calculated as equation described in following [23,24].

% inhibition of biofilm formation =

[(O.D control – O.D treatment) / O.D control] × 100

Results And Discussion

In this study showed the ability of *Staphylococcus aureus* and *Serratia marcescens* to biofilm formation;also the results showed the antibacterial activity of CFS and culture of *P. acidilactici* in Four method, in Co-culture method, the inhibition ratio was very good of CFS and higher ratio was when the treatment was (1:1) (medium : CFS), it was reach to 76% against *Staphylococcus aureus* and 80% against *Serratia marcescens*, this ratio was reduced when treatment was (medium 1.5 : CFS 0.5), it was 69% against *S. aureus* and 72% against *Serratia marcescens*. The lower ratio was 62 and 63 % against *Serratia marcescens* and *S. aureus* respectively when the treatment was (medium 1.75 : 0.25 CFS) – Table (1).This antibacterial activity of *P. acidilactici* against pathogenic bacteria may be explained by secreting *P. acidilactici* to many compounds including bacitracin, lactic acid, hydrogen peroxide and bio surfactant that exhibiting the activity as all probiotic [25].

Table (1): Inhibition ratio of *P. acidilactici* CFS against pathogenic bacteria by Co-culture method.

Treatment (medium : CFS)	Growth Inhibition ratio %	
	S. aureus	Serratia Marcescens
(1 : 1)	76	80
(1.5: 0.5)	69	72
(1.75:0.25)	62	63

Antagonistic activity of *P. acidilactici* culture against pathogenic bacteria by plug method is illustrated in Table (2). The higher diameter of inhibition zone 8 mm in third day against *Serratia marcescens*, whereas the lower diameter of inhibition zone 9 mm in first day against *S. aureus*.

Table (2): Antibacterial activity of *P. acidilactici* culture against pathogenic bacteria by Plug-method.

Culture of *pediococcus acidilactici* / Hours	Inhibition Zone (mm)	
	S. aureus	Serratia marcescens
24	9	11
48	11	15
72	15	18

This method allowed to the substances to diffuse from the plug to the agar medium, so the active substances of *P. acidilactici* will be contact with pathogenic bacteria cell and because of the spread of growth, when the lactic acid bacteria that cultured in MRS medium and incubated an aerobically for 48 to 73 hours at 28-30 C^{o} lead to increase concentration the inhibitory substances in MRS media. it can compete with the pathogenic bacteria on the nutrient in the medium and grow more quick than them, so it causes the inhibition the growth. This idea agrees with many of researchers that showed all probiotics have this mechanisms [18,26]. Also in the current study, the *P. acidilactici* culture improved the antibacterial activity against pathogenic bacteria by disk diffusion method the decrease in inhibition was very obvious comparative with Co-culture and plug method, when we see Table (3) we found *P. acidilactici* could inhibit the pathogenic bacteria just in (10) mm and (7) mm to *S. aureus* and *Serratia marcescens* respectively.

Table (3): Antibacterial activity of *P. acidilactici* culture against pathogenic bacteria by Disk method.

P. acidilactici culture	Inhibition zone (mm)	
	S. aureus	Serratia marcescens
Paper disks	10	7

Paper disk did not saturated with the active components of *P. acidilactici* because it is very thin and could not keep these components, for this reason, this method gave lower inhibition zone comparative with the two others method [27]. According to the results, the *P. acidilactici* CFS gave the best and larger inhibition zone against the pathogenic bacteria, so we choose it for following test after concentrated once just.

Table (4): Inhibition ratio of *P. acidilactici* CFS concentrated and non against biofilm production of pathogenic bacteria by ELISA system.

Pathogen Bacteria	O.D Reader of bioflim			The percentage of inhibition of biofilm production	
	Control	Treatment with			
		CFS nc	CFS c	CFS nc	CFSc
S. aureus	0.596	0.253	0.155	57.55	73.48
S. marcescens	0.667	0.278	0.143	58.32	77.68

*Control: (tested bacteria + medium without CFS)., *CFSc : CFS concentrated, *CFSnc : CFS not concentrated.

The efficiency of CFSc was larger than CFSnc because of aggregate the components in less quantity of CFS, this components can interference with the growth of bacteria and its virulence properties, these results are nearly similar to the results of another study since they found decrease in the production of biofilm after mixing with CFS [27], another source showed that effects of all *Pediococcus sp.* are sustained mainly by producing a group of organic acids like: succinic acids, lactic, propionic,acetic,...etc. That has the lethal effect on bacterial cell, these compounds are found in cell free supernatant of probiotics[1,28], in the same time, *Pediococcus sp.* especially *Pediococcus sp.* can live in different conation and resist the acidity in the medium, it is also able to utilize a variety of carbon sources for growth.[3]

Conclusion

This *study* was carried out to screen for *antimicrobial* activity that producing from the *P. acidilactici* (CFS and culture) against growth of pathogenic bacteria (*S. aureus* and *Serratia marcescens*) by (Co-culture, Plug and Disk method) and against biofilm formation by microtiter plate assay (OD/ELISA system). The principle of Co-culture assay & microtiter plate assay depends on dilutions technique, while plug & disk test depends on diffusion technique . The CFS and culture of *P. acidilactici* showed inhibitory activity against growth *S. aureus* and *Serratia marcescens* and their biofilm formation by quantitative analysis. The *P. acidilactici* need more experiments to confirm the inhibition ability on other pathogenic bacteria or microorganisms from different environments or other virulence factors.

Abstract

Background: Schizophrenia is a psychotic mental disorder that affects the activities of daily life, one of which is oral hygiene.These symptoms affect the ability of schizophrenic patients to clean their teeth and mouth, thus manifesting into the oral cavity. Teeth that are not cleaned give rise to plaque and its severity can be assessed by plaque index.

Objective: This study aims to determine the effectiveness of education and training teeth brushing on the knowledge, attitudes, and index of plaque.

Materials and Method: Quasi-experimental was conducted among schizophrenic (n= 104), with experimental group (n=52), and control group (n=52). The questionnaire distributed to 104 outpatients, to know the patient's level of knowledge and attitudes toward oral health, measurement of plaque index using TQHI (Turesky Modification of The Quigley-Hein Index). Education and training of teeth brushing are given to the experimental group with one-week intervals.

Results: Mann Whitney U test on the experimental-control group showed significant results with $p < 0.05$. Increased knowledge and attitudes are also showed by experimental groups with $p < 0.05$. The results showed there was a decrease in the plaque index in the experimental group compared to the control group.

Conclusion: Dental education is needed to improve the oral health of schizophrenic patients. In the future, it is expected that there will be an education and training program for scheduled toothbrushing outpatients for schizophrenia to improve oral health.

Keywords: *Dental education, schizophrenia, knowledge, attitude, plaque index.*

Introduction

Schizophrenia is a psychotic mental disorder characterized by major disorders in the mind, emotions,behaviors, various thoughts not logically interconnected, erroneous perception, flat or inappropriate aspects, and various disorders of motor activity bizarre. The symptoms of schizophrenia are shown to affect the activity of daily life, such as avolition. These symptoms indicate a lack of energy and an absence of interest to perform daily routine activities. Patients are not interested in dressing up and doing self-hygiene, such as uncombed hair, dirty nails, unbrushed teeth, messy clothes.[1]

Avolition symptoms affect the ability of schizophrenic patients to perform oral hygiene, thereby manifesting to the oral cavity. Uncleaned teeth cause plaque and severity can be assessed by the plaque index.[2] Plaque or biofilms are a collection of non-

mineral microorganisms organized in the organic matrix of mucopolysaccharides as the main etiological factor in the formation of dental caries and periodontal disease.[3] Dental caries and periodontal disease provide effects related to eating, nutrition, speaking, and quality of life.[4] It takes the role of a healthcare worker in a team involving medical and paramedics to provide dental education. Dental education is educational dental health to increase knowledge to change the attitude of the patient from not brushing teeth and eventually want to brush their teeth. The tooth brushing action reduces plaque, so caries and periodontal disease can be prevented. The oral health problems in schizophrenia are the accumulation of schizophrenia symptoms, lack of knowledge, lack of motivation, feelings of fear in dental examinations, side effects of psychotic drugs to oral health.[5]

Dental caries and periodontal disease are the most common diseases in schizophrenia patients. Some studies have shown high Decay Missing Filling Teeth (DMFT) figures than the general public, as well as periodontal disease. Periodontal disease caused by plaque resulted in damage to periodontal tissue so that the tooth regardless of the socket, therefore many patients schizophrenia lose teeth.[6,7] Dental health and mouth are also getting worse with the habit of poor schizophrenia patients such as smoking and lack of tooth brushing frequencies as well as consuming karyogenic foods. Side effects of medications consumed by the patient during treatment also affect the decreased flow of saliva in the oral cavity.[8]

Dental education is very necessary for the improvement of knowledge, attitudes, and a decrease in the plaque index of schizophrenia patients. Dental education may be administered in schizophrenia patients in circumstances where symptoms are shown to be controlled, cooperative, not in acute/aggressive attacks, not in the treatment of epilepsy and cerebrovascular problems. The role of family and people who care for patient schizophrenia is very important to maintain the health of his mouth.[9] This study aims to conducted to assess the effectiveness of education and training teeth brushing on the knowledge, attitudes, and index of plaque in schizophrenic patients.

Method

Subjects are carried out by data on the outpatient diagnosed with schizophrenia. Sample study (n=104) divided into 2 groups, 1 experiment (n=52) given education and others as a control (n=52). Criteria for inclusion of respondents in the following studies is an outpatient who regularly takes the drug 1 week once in Mental Hospital Soeprapto Propinsi Bengkulu (MHSPB) with a diagnosis of schizophrenia. The patient's condition is stable and has been treated with psychotic drugs. The patient can be independent, age 18-55 years, can read and write, can communicate verbally well, cooperative, willing to be a respondent. Patients with limited motor movements. Patients in unstable conditions (rowdy), edentulous, in toothache conditions were excluded. The study was approved by Institutional Ethical Committee the faculty Dentistry University of Gadjah Mada.

Demographic data and information on medical were obtained from institutional electronic records. These included age, gender, level of education, duration of disease, history of smoking. Informed consent was taken from the study participants and their attendants. The validity and reliability of the questionnaire were 30 respondents. Education 2 times with a distance of 1 week, how to brush the tooth modified Bass in the dental model as well as training teeth brushing by the patient. The study was conducted using the first observation (pretest), interview patients, a questionnaire filled, then assessed the plaque index. After 1 week of second dental education. Post test and plaque index assessments were implemented after 1 week of second dental education. The control group performs pretest, post test and plaque index assessments. Assessment of plaque Index of study responders in the dental room is conducted by 2 calibrated dentists, Cohen's kappa coefficient was 0.88.

Assessment of dental hygiene with Turesky modification of the Quigley-Hein Index (TQHI) method. For the assessment of plaque on the surface of the teeth, the teeth were stained with a plaque dye (GC Tri Plaque ID Gel), then assessed whether the precipitate was painted on the surface of the labial teeth after administration of the material.The individual plaque score is obtained from the total amount of the obtained value divided by the number of inspected surfaces, the valuation range from 0 to 5.

The data were analyzed using SPSS version 24. The normality test was carried out using Kolmogorov Smirnov,test homogeneity using Levene's and Mann Whitney U test with the significance level was set at $p < 0.05$

Result

Table 1 have showed the frequency distribution of 104 patients, the results that most male-sex patients as 77.9%, the rest of the sex women as 22.1%. The majority

of respondents were 31-35 years old by 27.9%, and at least 46-50 years old and 51-55 each year as much as 4.8%.

The last education of the majority of junior high school graduates is 30.8%, at least not as much as 1.9%. Smoking status of schizophrenia patients is mostly smoked as much as 74.0%, and the rest do not smoke as much as 26.0%. Furthermore, patients who rarely eat sweet as much as 51.9%, and often eat sweet as much as 48.1%. In addition to sweet foods also most of the patients often drink sweet as much as 79.8% and the rest rarely drink sweet as much as 20.2%. The results of p sig values all above 0.05 mean there is no significant difference in the respondent's characteristics based on the experiment and control group.

Table 3 showed the average value and the default deviation of the knowledge variable, attitude, and plaque index. This shows increased knowledge, the attitude of schizophrenia patients and significantly decreased plaque index value in the experimental group.

Table 3. Descriptive average and standard deviation of knowledge, attitude, plaque index in groups experiment and control

Treatment	Time	N	Experiment	Control
Pre test	Knowledge	52	10.48 + 1.49	10.35 + 1.70
	Attitude	52	51.25 + 2.35	51.98+ 2.91
	Plaque Index	52	2.92 + 2.83	2.82 + 0.73
Post test	Knowledge	52	14.79 + 0.96	10.62 + 1.66
	Attitude	52	55.83 + 4.21	52.19+ 2.91
	Plaque Index	52	1.31 + 0.65	2.78 + 0.68

The MannWhitney U test to determine whether there is a significant difference between the experimental treatment and control group, it showed on table 4. MannWhitney U test results showed that all post-test variables of knowledge, attitudes, plaque index based on the Experiment - control group had a p value of significance of 0.000 ($p < 0.05$).

Table 4. Mann Whitney U test of knowledge, attitudes, plaque index

Treatment	Variable	Mann Whitney U		Description
		Z value	Significance level (P)	
Pre test	Knowledge	0.477	0.634	Not significant
	Attitude	1.149	0.251	Not significant
	Plaque Index	0.759	0.448	Not significant
Post test	Knowledge	8.583	0.000	Significant
	Attitude	4.364	0.000	Significant
	Plaque Index	7.588	0.000	Significant

Discussion

Schizophrenia is a chronic mental illness that causes impaired thought processes, distortion of reality, disorganization, reduction of psychomotor, difficulty distinguishing between reality and the content of self-thought.[10] Some study depicts the gender of men more schizophrenia than women.[4,6] The results of the frequency distribution showed that the majority of male-sex patients were 77.9%, the rest of the female gender was 22.1%. The majority of respondents were 31-35 years old as much as 27.9% with a status not working as much as 63.5%.

Characteristics of schizophrenia patients also affect the health of their teeth and mouth. The characteristic in question is gender, age, occupation, education, smoking habit, consumption of food and sweet drinks between the hours of eating and the duration of schizophrenia. This study also describes the characteristics of the respondents who have schizophrenia patients as described above. Patients who rarely eat sweet by 51.9%, and often eat sweet as much as 48.1%. In addition to sweet foods also most of the patients often drink sweet as much as 79.8% and the rest rarely drink sweet as much as 20.2%.

Dental education can be given in several method such as lectures, dialogue, panel discussion, brainstorming, demonstration, group discussion, workshops, seminars, symposiums, field exercises, system modules, socio drama and others.[11] Study on dental education in schizophrenia patients is very rare because of the many things associated with the condition of schizophrenia patients, such as symptoms that arise as well as the side effects of drugs consumed by patients Schizophrenia.[10] Previously study has reported thateducational program given in mental disorders patients there are 5 causes of tooth loss, perforated tooth, periodontal disease, dental hygiene, routine visiting dental health facilities.[12,13] The results are the same as the studies conducted where there was an increase in knowledge and attitudes in patients after dental education.

Schizophrenic respondents at this study have value of significance ($p < 0.05$), meaning that the plaque index post test data shows a significant difference between experiment-control.Plaque index posttest scores of the two groups had different mean values, meaning that the posttest plaque index of the experimental group was 1.31 better (lower) than the post-control plaque index of 2.78 with a mean of 1.47. It can be concluded that brushing education and training can reduce the plaque index of schizophrenic respondents. Brushing teeth well can remove plaque that sticks to the surface of the teeth, either ordinary toothbrushes or electric toothbrushes.[14]

Conclusion

Schizophrenia is a psychotic disorder with negative symptoms make teeth is not clean, causing a build-up of plaque on the tooth surface. The dental hygiene level is assessed by the plaque index by looking at the number of plaque on the tooth surface that has been given a disclosing solution. Plaque is a collection of bacteria as a major factor in the occurrence of caries and periodontal disease. Poor dental and oral health is associated with eating disorders, nutrients, speech, quality of life. Overcoming these schizophrenia patients should be given the education to increase knowledge and change his attitude so that there is a decrease in plaque index.

Conflict of Interest: None

Source of Funding: Research funding assistance from Ministry of Health of the Republic of Indonesia 2019.

Ethical Approval: Ethical clearance was obtained from Institutional Ethical Committee (No. 00342/KKEP/

FKG-UGM/EC/2020) the faculty Dentistry University of Gadjah Mada.

Abstract

This study was to determine the influence of environmental factors and social-cultural toward the incidence of diarrhoea. The methodology used in this study is a quantitative method by applying an analytical survey with a cross-sectional approach. The population of this research was all mothers who have babies in the Lueng Keube Jagat Health Center in Working Area Tripa Makmur Subdistrict, Nagan Raya Regency, as many as 1.792 mothers. Further, the sample is taken by implementing a simple random sampling technique, as many as 95 mothers. Data analysisused in this study is univariate, bivariate and multivariate analysis. The results showed that there was a significant influence between the environmental factors (p value <0,05, RP = 15,9) and socio-culture factors (p value <0,05, RP. 14,0) with the incidence of diarrhoea in infants.

Keywords: *Environmental factor, Social Culture, Diarrhea, and Toddlers.*

Introduction

Diarrhoea is a condition in which the faeces excreted abnormally. The abnormality occurs increasing of volume of faeces a liquid and the frequency of the excretion either with or without bloody mucus, which is three times or more a day[1]. A person is said to suffer diarrhoea when he/she excretes more mucous faeces, or defecates three times or more, or excretes mucus faeces without blood within 24 hours.[1]

There are some right and practical actions that can prevent diarrheal disease, generally by living a healthy life. Some practices can do the prevention of diarrhoea in children. There are a fully breastfeeding the baby for six months, providing complementary feeding to get used to adult food gradually, disposing baby's faeces correctly, and giving measles immunization immediately after they are nine months old. Another activity that can prevent the occurrence of diarrhoea is by creating a healthy environment, consisting of providing clean water, waste management, and wastewater disposal[2]. Clinically, the causes of diarrhoea grouped into six factors, which are infection (bacteria, viruses, parasites), allergies to foods such as spicy food, etc., poisoning, immunodeficiency, and other causes.[2]

Human behaviours or activities are someone's responses to stimuli associated with illness and disease. These behaviours include improving and maintaining health, preventing illness, seeking treatment, and caring for health care, food, and environment systems. Also, it contains behaviours towards the environment. Moreover, health behaviour is also necessary since it relates to someone's actions in maintaining and improving health, including efforts to prevent disease, maintain personal hygiene, choose food, and take care of sanitation. According to WHO and UNICEF, there are around 2 billion cases of diarrhoea occurring every year worldwide. Of all deaths of children under five due to diarrheal disease, 78% occur in the African and Southeast Asia.[3]

The number of diarrhoea cases in Indonesia in 2012 was 1,654 cases and resulted in the death of 34 people. Whereas in 2013, the number of diarrhoea cases was as many as 646 cases with seven fatalities.[4] The number of evidence in Indonesia in 2014 was estimated at 8,713,537 cases, while the cases handled were 8,490,976 cases.[5] In 2015, the name of the cases estimated at 5,405,235 cases and the cases handled were only 4,017,851 cases.[4]

In Aceh Province, the number of diarrhoea cases in 2013 was estimated at 196,948 cases, of which 98,525 (50.03%) were experienced by men and 98,423 (49.97%) experienced by women. The number of cases handled was limited to 107,582, of which 51,343 cases (52.1%) in men and 56,239 cases (57.1%) in women[4]. In 2015, the cases estimated at 101,368 cases and the number of diarrhoea cases handled was only 64,589 cases.[4]

Specifically, in Nagan Raya Regency, the number of diarrhoea cases in 2014 was estimated at 2,521 cases (2.10%), and the number of cases handled was 2,438 cases (93.13%). Meanwhile, in 2015, the cases were estimated at 3,517 cases (3.20%), and the cases handled were 3,286 cases (93.4%). In 2016, the cases estimated at 3,496 cases (2.25%) and those handled were 3,329 cases.[6]

Based on observations in the field, it is seen that many infants experience diarrhoea in the work area of the Health Center of Lueng Keubeu Jagat because of the less clean environment and unhealthy behaviours of the family.[7] This statement based on the results of the interviews with twelve mothers who have 0-1-year-old babies. From the interview, there were nine mothers whose babies had experienced diarrhoea and some even vomiting with diarrhoea. Three mothers stated that this happened because their children had been fed with stale milk, while the other two claimed their carelessness caused the diarrhoea for good supplementary food given to the children. The mothers followed their parents' advice to abstain from certain foods during childbirth which had been a tradition or culture for generations, but they do not know that these are the cause of diarrhoea in infants. The other four mothers said that their children had diarrhoea because their children were eating not suitable food, e.g. not proper porridge.

Method

This study is a survey with a cross-sectional approach, where the free and bound variables studied at the same time. This study aims to find out the effect of environmental and social culture on the occurrence of diarrhoea in infants the Health Center of *Lueng Keubeu Jagat*, *Nagan Raya* Regency, Indonesia. The study carried out from November 16, 2017, to February 8, 2018. The population of this study was 1,792 mothers who had babies 0-59 months in the *Lueng Keube Jagat*. The sample used in this study was 95 mothers who had babies from 0 to 59 months, who were selected by simple random sampling.

Results

Respondents' Characteristics: Concerning the Distribution of Respondents about Environmental Factor on Diarrhea Occurrence, the following information obtained through univariate analysis. It obtained from the questionnaire that mothers who used clean water every day are only 34 mothers out of 95 (32%). Then, those who use the health-standard toilet, whose house has a good garbage dump, who have good sewage site, who always cover their babies' food and equipment, and who use boiled water for baby's milk are only 37 out of 95 respondents (37%), equally. While the other 58 mothers do not conduct all these practices. Concerning environmental and socio-cultural factors, it obtained that mothers coming from a good environment are 41 mothers (43.2%) while those coming from the poor environment are 54 mothers (56.8%). Then, those coming from the supportive social culture are 38 mothers and who do not are 57 mothers.

Regarding the socio-culture factor, the information is as in the following. In regards to socio-cultural support, there are only 31 mothers who give ORS when their babies are experiencing diarrhoea. The rest do not. And 29 of them carry the baby herbs to cure his/her diarrhoea instead of taking him/her to the health centre. However, 66 mothers do not do this. Next, 37 mothers believe that they should avoid particular food after giving birth. Later, 31 of them stated that newborns should only be breastfed, while only 37 agreed that they should be fed on bananas or other complementary food. However, 66 mothers believe that diarrhea in babies is not common, while the rest think it is common because they still eat a little amount of food. Furthermore, there are only 41 mothers who informed that their babies have three bowels movement a day, while the rest do not. And on average, there are 44 mothers whose children have experience diarrhoea as infants.

Bivariate and Multivariate Analysis: Later, concerning the results of the bivariate analysis, the information is as shown in the tables below.

Table 1. The Influence of Environmental Factors on the Diarrhoea Occurrence

Environment	The Occurrence of Diarrhea				Total		p-Value	RP
	Yes		No					
	f	%	f	%	f	%		CI 95%
Good	2	4.9	39	95.1	41	100	0.000	15.944
Poor	42	77.8	12	22.2	54	100		(4,096-62,071)

Based on the result of the chi-square test, it obtained the-value is 0,000 <α = 0.05 so that there is an influence of environmental factor on the occurrence of diarrhoea in the area where this research conducted. Further, the results of RP = 15.944 shows that the poor environment has a risk of 15,944 times for the occurrence of diarrhoea in infants in the area.

Table 2. The Influence of Social and Cultural Factor on Diarrhoea Occurrence

Socio-culture	The Occurrence of Diarrhoea				Total		p-Value	RP
	Yes		No					
	f	%	f	%	f	%		CI 95%
Supportive	2	5.3	36	94.7	38	100	0.002	14.000
Unsupportive	42	73.7	15	26.3	57	100		(3.601-54.429)

The p-value = 0,002 <α = 0.05 proves that there is an influence of social and cultural factor on the occurrence of diarrhoea and the results of RP = 14.000 shows that the unsupportive social and cultural environment has a risk of 14,000 times for the occurrence of diarrhoea.

Table 3. The correlation between Environmental and socio-cultural variable on infant diarrhoea occurrence

Variable	Category	p-value	95% CI
Environment	Good Poor	0,000	4,634 - 341,243
Social and Culture	Supportive Unsupportive	0,002	2,445 – 232,325

The logistic regression test results with p <0.05 (95% CI: 4,634 - 341,243), this shows that there is a powerful influence between the environment on the incidence of diarrhoea in infants. Likewise, socio-cultural variables show that the value of p <0.05 (2,445 – 232,325), proves that there is a strong influence between social culture on the incidence of diarrhoea in infants.

Discussions

Environmental Impacts: First, below is described the results concerning the environment impact on diarrhoea occurrence in infants. Despite the fact of living in a clean environment, the mothers whose children encountering diarrhoea caused by the mothers' negligent behaviour of not minding the cleanliness of their babies. Contrarily, the mothers who lived in a clean environment and did not have infants encountering diarrhoea was because the children's hands regularly washed, and their food was always covered. Hence, it can be claimed that flies are one of the factors causing diarrhoea in infants.[8]

Besides uncovered food, those living in an unclean domain and had their children encountering diarrhoea was because there was a lot of food waste smelling extremely horrible and, again, invites flies. This condition is exceptionally perilous for children's health.[9] Likewise, the kitchen utensils were also not covered.[10] This finding is following the consequences of different studies expressing that mothers' behaviour affects diarrhoea occurrence in infants.[11]

As indicated by Mwambete and Joseph, there are a few factors that extend the danger of babies encountering diarrhoea, for example, ecological elements that incorporate waste arrangement, sewage and water sources. Inappropriate handling of waste and sewage can also cause diarrhoea. This condition caused because the flies that have landed on garbage will later land on food. Moreover, diarrhoea can happen through polluted water, either from its source or from the storing place at home.

Another factor is housing and settlements. Settlements are a piece of the environment that may be out of individual control both in urban and remote areas. It works as neighbourhoods/individual situations and where the activities to help the livelihoods done. Housing and settlements are two things that cannot be isolated and firmly identified with monetary action issues, industrialization and local development.[12] This result is in line with Marlina's study (2015) expressing that there was a massive impact of environmental cleanliness on the diarrhoea occurrence in the family unit setting in KedaungWetan Tangerang region[13]and the relationship between the incidence of healthbehavior based on environmental sanitation aspects.[14]

Muliati (2017) found that the level of children under five years old who suffered from diarrhoea in the last 3 months was 89.1%, while those who lived in a clean environment was only 4.2%. The p-values of was precisely 0.000> α 0.05, so it deciphered that there was a connection between environment and diarrhoea occurrences in the Mangkang Health Center[15]. Moreover, Megasari (2015) further obtained that those living in poor environmental sanitation was 0.265 occasions higher to experience diarrhoea compared to those living in great natural sanitation in Barito Kuala. Godana and Mengiste(2013) suggest that the absence of ecological sanitation will expand the occurrence of diarrhoea.[16-17]

Socio-cultural Impacts: Second, the description of the results concerning the social and cultural impact is as follows. The researchers found that those living in a steady and social condition and having diarrhoea children, was because they lived in n their relatives' homes. For example, the baby was allowed to play in muddy puddles. Besides, the mothers choose to give breast milk directly, not using bottles. This practice can minimize the risk of diarrhoea.[16] Respondents who lived in an unsupportive social and cultural condition and had a child encountering diarrhoea spurred by the behaviour of the moms who did not exactly think about one another, and there was no frequent collaboration. The infants were permitted to play uninhibitedly as long as it was not risky. However, this circumstance made the infant experience diarrhoea.[17]

Culture is a way or frame of the human mind in managing nature and environment which incorporates the results of imagination, taste, goal, and work either physically, mentally, colloquially, or spiritually.[18] Culture regards all parts of human life, both material and non-material. Most specialists see that culture will create from a straightforward stage to an increasingly perplexing stage.[19] The study uncovered the impact of waste arrangement on the diarrhoea occurrence in children in Pallangga Public Health Center, Gowa (p-value 0.02820).[20] The study additionally found the effects of social and culture on the diarrhoea occurrence in children under five years old in Aceh Baroh Pasie Town, which situated in Meureubo, West Aceh.

This examination is in accordance with Ogbo, Aina, and Aderemi (2014), in regards to the connection between ecological sanitation and social variables and diarrhoea occurrence.[21] Children and environmental cleanliness impact both on children's physical and psychological entity.[22] Children living in poor conditions maintain intestinal worms and diarrhoea. Thus, sufficient educational supervision to generate a clean environment for children's growth and development is profoundly necessary.[23]

Conclusions

There is an influence of environmental and social and cultural factors on the occurrence of diarrhoea in infants (p-value <0.05), but the environmental factor has a more significant impact on the appearance of diarrhoea in infants. Further research is needed to see the possibility of other factors that influence the occurrence of diarrhoea in infants.

Abstract

Background: Sinapic acid is one of the phenolic acids that widely distributed in edible plants such as cereals, nuts, oil seeds and berries. Sinapic acid shows antioxidant, antimicrobial, anti-inflammatory, anticancer, and anxiolytic activity.

Material and Method: The present study was conducted based on monitoring of in vitro cytotoxicity using MTT assay. Nano-capsulation was performed using Tween-80, and biochemical changes concerning reactive oxygen species (ROS) profile.

Findings: Data recorded revealed that the inhibitory concentration (IC_{50}) of free and Nano-capsulated sinapic acid was 646.4 µM/ml and 84.74 µM/ ml post treatment respectively. Also, cytotoxicity was concentration dependent with significant difference between free and Nano-capsulated one. Also, ROS as a biomarker was elevated in a significant way than in case of Nano-capsulated sinapic acid. In the meantime the biochemical marker (ROS) was changed post cell treatment with both formulae of sinapic acid.

Conclusion: Nano-capsulated sinapic acid is more effective as cancer chemopreventive agent with much lower concentration than free sinapic acid on HEp-2 cell line.

Keywords: *HEp-2 cells, apoptosis, Sinapic acid, Nano-capsulated Sinapic acid, ROS.*

Introduction

Cancer remains one of the highest causes of death globally. Various types of chemotherapies fail due to adverse reactions, drug resistance, and target specificity of some types of drugs. There is now emerging interest in developing drugs that overcome the problems stated above by using natural compounds, which may affect multiple targets with reduced side effects and which are effective against several cancer types[1]. Head and neck squamous cell carcinoma (HNSCC) is one of the most common cancers worldwide and account for more than half million new cases and 380,000 deaths per year[2] HNSCC, one of the most common cancers with high morbidity and mortality rates worldwide, has a poor prognosis. HNSCC ranks eighth in mortality among all cancers[3]. Chemoprevention is a strategy to inhibit, delay or reverse carcinogenesis in humans, using natural or synthetic chemical agents. Medicinal plant and its

derivatives act as anticancer agents against different type of cancers. Two-third of the human cancers can be eliminated by lifestyle modifications including dietary changes. Consumption of foods rich in natural phytochemicals can reduce the risk of several types of cancers. Despite the significant amount of research, a clear understanding of the individual component in the plants that can prevent cancer is not comprehensive[4].

Despite significant progress in the fields of cancer diagnosis and chemotherapy, cancer remains one of the greatest causes of death worldwide. Novel approaches to cancer management often fail due to frequent genetic alterations and mutations in cancer genomes. Because of the high frequency of side effects caused by chemotherapy, metastatic cancers still need new, more effective chemotherapeutics. There is emerging interest in developing drugs to tackle these problems by using natural compounds. Natural compounds from various sources including plants, animals, and microorganisms offer a great opportunity for discovery of novel therapeutic candidates for the treatment of cancer [1]. Natural products are important sources of bioactive molecules, due to the structural diversity of their constituents. The discovery of effective anti-cancer drugs from natural products plays an important role in cancer chemotherapy [5]. Phenolic compounds are a group of key plant metabolites found abundantly in fruit and vegetables. Because of their antioxidant properties, they play an important role in preventing various disorders or diseases related to oxidative damage [6].

Phenolic compounds exhibit a wide range of physiological properties, such as antioxidants, antiallergic, anti-inflammatory, anticancer, antihypertensive and antimicrobial agents[7]. Nanotechnology has the power to radically change the way cancer is diagnosed, imaged and treated. Currently, there is a lot of research going on to design novel nanodevices capable of detecting cancer at its earliest stages, pinpointing its location within the body and delivering anticancer drugs specifically to malignant cells[8].

Sinapic acid is a small naturally occurring hydroxycinnamic acid derivative. It is a phenolic compound and a member of the phenylpropanoid family, the member that is assumed as therapeutically beneficial and generally not toxic. Sinapic acid is widespread in the plant kingdom (fruits, vegetables, cereal grains, oilseed crops and medicinal plants) and is common in human diet. Derivatives of sinapic acid are characteristic compounds of the *Brassicaceae* family. Sinapic acid shows antioxidant, antimicrobial, anti-inflammatory, anticancer, and anxiolytic activity. 4- vinylsyringol (a decarboxylation product of sinapic acid) is a potent antioxidative and antimutagenic agent, which suppresses carcinogenesis and the induction of inflammatory cytokines. Sinapine (sinapoyl choline) is considered to be an acetylcholinesterase inhibitor which might have therapeutic applications in various disease treatments [9]. The present study aimed to evaluate cytotoxicity of free and Nano-sinapic acid on HEp-2 cell line monitoring relatively to the reactive oxygen species as anticancer biomarkers.

Material and Method

Sinapic acid (3, 5-dimethoxy-4-hydroxycinnamic acid) with molecular weight of 224.21 g/mol was supplied from (Sigma Aldrich- USA), Nano-sinapic acid was prepared using bio surfactant (tween 80) (Nano-Tech Egypt for Photo-Electronics) and Human squamous cell carcinoma cell line (HEp-2) used in the present study was supplied from Cell Culture Department-VACSERA-EGYPT.

Cytotoxicity Assay (MTT assay): In the present study, Methyl Thiazol Tetrazolium (MTT) assay is a quantitative colorimetric method to determine cell proliferation. It utilizes yellow tetrazolium salt (3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide) which is a water soluble salt reduced to an insoluble purple formazan complex by cleavage of the tetrazolium ring by lactate dehydrogenase within the mitochondria. The cell membrane is impermeable to the formazan product and therefore it accumulates in healthy cells. The resulting intracellular purple formazan crystals can be solubilized and quantified by spectrophotometric means. This reduction takes place only when mitochondrial reductase enzymes are active, and therefore conversion can be directly related to the number of viable (living) cells. The MTT cell proliferation assay measures the cell proliferation rate and conversely, when metabolic events lead to apoptosis or necrosis, there is reduction in cell viability. For each cell type, there is a linear relationship between cell number and signal produced, thus allowing an accurate quantification of changes in the rate of cell proliferation[10].

The viability of HEp-2 post treatment with either free and Nano-sinapic acid was determined 24 hours.

For MTT assay, HEp-2 cells were seeded in 96-well culture plates and treated with 10 uM/ml sinapic acid for 24 hours. MTT as 50µL of 0.5mg/ml stock solution were dispensed to the treated wells and incubated at 37°C for 4 hours. Thereafter, the treatment medium was gently removed from the wells, cells were washed using PBS and 50µL of Dimethyl sulfoxide were added to each well to dissolve the purple formazan crystals. The absorbance was conducted at 570nm using the Dynatech MR5000 spectrophotometer. The absorbance values at 570nm were relative to the number of residual viable cells.

Determination of Reactive Oxygen Species: This immunoassay kit allows in vitro quantitative determination of Rat reactive oxygen species, ROS concentrations in serum, tissue homogenates and other biological fluids.The microtiter plate provided in this kit has been pre-coated with an antibody specific to ROS. Standards or samples were added to the appropriate microtiter plate wells with a biotin-conjugated polyclonal antibody preparation specific for ROS and Avidin conjugated to Horseradish Peroxidase was added to each microplate well and incubated. Tetramethylbenzidine substrate solution was added to each well. Only those wells contain ROS, biotin-conjugated antibody and enzyme-conjugated Avidin exhibited a change in color. The enzyme-substrate reaction was terminated by the addition of a sulphuric acid solution used as 2% and the color change was measured spectrophotometrically at a wavelength of 450 nm. The concentration of ROS in the samples was determined by comparing the optical density of the samples to the standard curve.

Results

Cytotoxicity Assay: Regarding the cytotoxic effect of free and Nano-sinapic acid on HEp-2 cells, viability was employed using MTT assay. Data recorded revealed that the mean viability percentage of Sinapic acid and Nano-capsulated Sinapic acid treated cells was concentration dependent [Fig. 1]. The IC_{50} values determined were 646.4 µM/ml and 84.74 µM/ ml for free and Nano- capsulated sinapic acid respectively indicating a significant difference [Fig. 2].

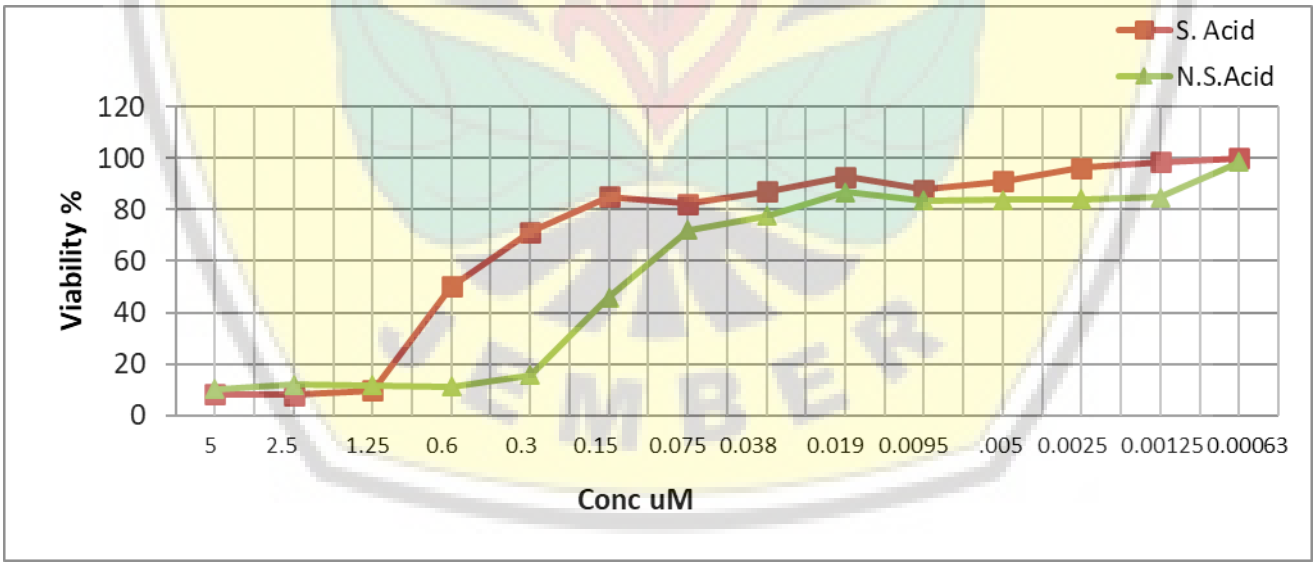

Figure (1): Evaluation of cell viability post treatment with both free and Nano-capsulated Sinapic acid using MTT assay

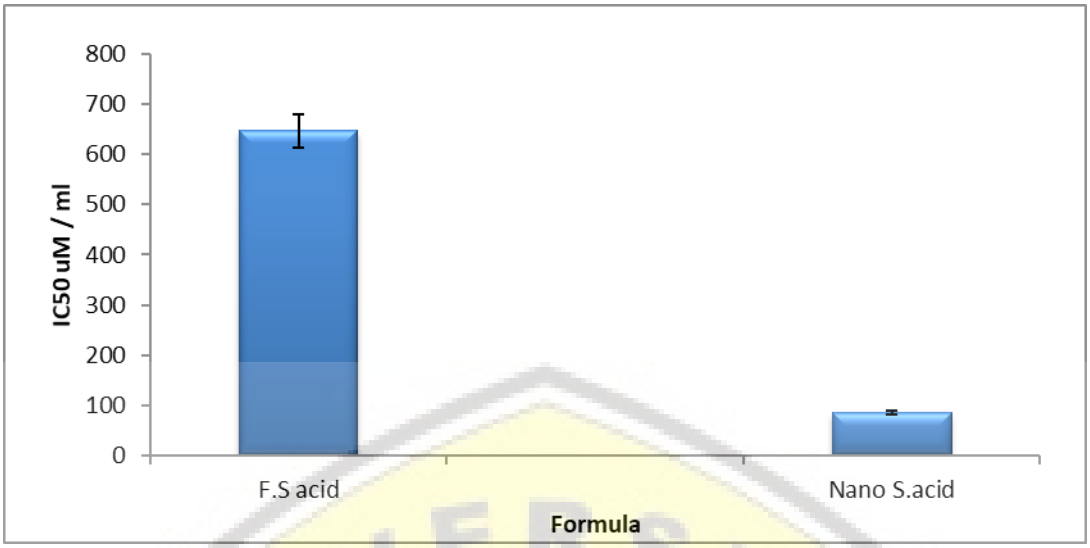

Figure (2): Evaluation of inhibitory concentration (IC_{50}) post HEp-2 cell treatment with free and Nano-sinapic acid.

Determination of Reactive Oxygen Species: The intracellular ROS level was increased in Sinapic acid and Nano-capsulated sinapic acid treated cells as compared to the untreated cells but Nano-capsulated sinapic acid cause significant increase in the intracellular ROS level than in case of free Sinapic acid treated cells [Fig.3].

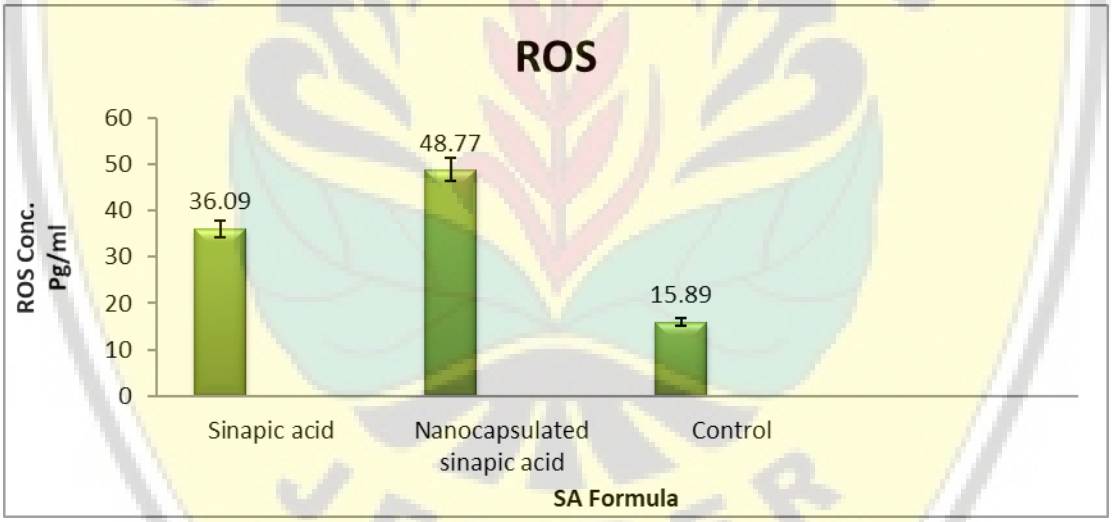

Figure (3): Bar chart revealing generation of ROS level post free and nano-sinapic acid treatment measured spectrofluorimetrically for 24 hr versus control cells.

Discussion

For thousands of years, the natural products have played an important role throughout the world in the treatment and prevention of human diseases. Over 60% of currently used anticancer agents are derived in one way or another from natural sources [11]. Sinapic acid is a small naturally occurring hydroxycinnamic acid derivative. It is a phenolic compound and a member of the phenylpropanoid family, which are assumed as therapeutically beneficial and generally not toxic compounds [(9)]. Additionally, ***Reddy and Prasad, 2011*** [12] have shown that phenolic compounds have health protective effects as well as are cytotoxic to cancer cells. Sinapic acid and other phenylpropanoids are present in vegetables and grains, e.g., Brassica juncea L., hazelnut, pea, cabbage, wheat, or brown rice [13]. Therefore, this

study was conducted to explore the in vitro cytotoxicity of free and Nano-capsulated sinapic acid on squamous cell carcinoma (HEp-2). The results of this study showed that the cytotoxicity was concentration dependent with significant difference between free and capsulated one but Nano- capsulated sinapic acid was significantly effective than free one. These results suggest that both formulae of sinapic acid could effectively inhibit the proliferation of the HEp-2 cells but Nano-capsulated sinapic acid was more effective than the free sinapic acid. In line with the present results is the findings revealed by ***(Kampa et al., 2004)*** [14] who documented that sinapic acid inhibits T47D human breast cancer cells in a time and dose dependent manner. Similarly, ***Roy et al., 2002*** [15] stated that the natural phenolic compounds curcumin, resveratrol, and capsaicin act as chemopreventive agents by inducing apoptosis in tumor cells.

In the present research, to evaluate the antioxidant properties of free and nano-sinapic acid, the intracellular ROS level was measured in HEp-2 cells treated with sinapic acid and nano-sinapic acid after 24 hours. In the present work, it was found that the intracellular ROS levels were increased in sinapic acid and nano-sinapic acid treated cells as compared to the control untreated cells.

The precise role of ROS in the signaling of apoptosis is very complicated, as both the intrinsic and extrinsic pathways are known to be associated with ROS [16]. Previous report demonstrated that oxidative stress induced by chemopreventive drugs reduced MMP and caused cyt-c to be released from the mitochondria, resulting in the activation of caspase-9 [17]. Mitochondria is a key organelle for the cell survival and are a source of ROS generation during apoptosis, reduced MMP can lead to increased generation of ROS and apoptosis [18]. The anticancer effect of sinapic acid is revealed by its ability to decrease the MMP, and thereby induce apoptosis in HT-29 and SW480 colon cancer cells [19]. In this context, ***(Galati et al., 2002)*** [20] have suggested that dietary phenolic compounds alter MMP and induce mitochondrial collapse. ROS has been implicated as a messenger in multiple signaling pathways and can play a significant role in the apoptotic process by regulating the activity of certain enzymes involved in the cell death pathway [21].

The present findings are in line with finding reported by ***Kalaimathi et al., 2014*** [22] who revealed that laryngeal carcinoma cells on treatment with sinapic acid demonstrated increased intracellular ROS levels and thereby loss of MMP. Additionally, the current findings are in accordance with that reported by ***Chandrasekaran et al., 2014*** [19] who revealed that sinapic acid acts as an antiproliferative agent in colon cancer cells through over production of ROS, apoptotic induction and the loss of MMP. Therefore, the present results propose that oxidative stress is apart in sinapic and nano-sinapic acid could induce cytotoxicity. Thus, both formulae of sinapic acid initiate cancer cell death by inhibiting cell proliferation, altering mitochondrial membrane potential, increasing intracellular ROS and inducing apoptosis in squamous cell carcinoma cell line.

Conclusion

Sinapic acid possesses cytotoxic effect on cancer cells so can be used for cancer prevention and cancer chemotherapy while Nano-capsulated sinapic acid possesses more cytotoxic effect on cancer cells with much lower concentration than sinapic acid. Thus, Nano-capsulated sinapic acid is more effective as cancer chemopreventive agent than free sinapic acid on squamous cell carcinoma.

Effectiveness of Health Education Program on Nurse's Practices toward Hydrocephalus Neonatal Baby Care at Intensive Care Unit at Medical City Complex in Baghdad City

Sarab Honaitah Baewy[1], Afifa Radha Aziz[1]

[1]Pediatric Nursing Department, College of Nursing/Baghdad University, Iraq

Abstract

This study aim to: Assessing the nurse's practices toward hydrocephalus neonatal baby care. Constructing an educational program for nurse's practices toward hydrocephalus neonatal baby care. Applying the educational program for nurse's practices toward hydrocephalus. Finding the relationships between the nurse's practices toward neonatal with hydrocephalus and socio-demographic characteristics such as (age, gender, level of education training session). Evaluation the effectiveness of an educational program for nurse's practices toward hydrocephalus neonatal baby care. Descriptive analytic (quasi experimental) design with application of a pre-test/post –test approach is conducted for the period of 7th October 10th April 2019. Non-probability (Purposive)sample of (30) nurse's working in Neonatal Intensive Care Unit (NICU) was chosen .Preliminary study, which consist of (14) nurse's, is to assess nurse's practices toward hydrocephalus neonatal baby care and prepare an educational program with pre and post-test questionnaire. The study finding effectiveness of an educational program toward hydrocephalus nurse's practices neonatal baby care, the results indicated that there is high significant difference among nurse's knowledge and practices pre-test and post-test at p-value =0.001 . which indicated that the program is effective evidence by difference in mean of nurse's knowledge and practices

Introduction

Hydrocephalus is considered a long-term condition, normally identified in early childhood, where there is excessive cerebrospinal fluid (CSF) in the ventricular system within the brain. The increased level of CSF causes ventricular enlargement resulting incompression and destruction of adjacent structures that affect brain growth and development. Seventy percent of children with hydrocephalus are managed by the insertion of a ventricular shunt, which diverts excessive fluid from the ventricles to another body compartment, commonly the peritoneum[1] Cerebrospinal shunts are considered to be permanent catheters in which the proximal end of the shunt is in the cerebral ventricle, an intracranial cyst, or the lumbar subarachnoid space; the distalend usually terminates in the peritoneal, pleural, or vascular space. A ventricular shunt is a small tube that is placed in the child's head, which carries extra fluid from the head to the abdomen, where it is absorbed. A ventricular peritoneal shunt is a medical device that relieves pressure on the brain caused by CSF accumulation. Normally, the CSF passes through the brain's ventricles to the base of the brain. The fluid then bathes the brain and spinal cord before it is reabsorbed into the blood. When this normal flow is disrupted, the buildup of fluid can create harmful pressure on the brain's tissues, which can damage the brain[2,3]. Ventirucular peritoneal shunting is the standard therapy for the management of hydrocephalus, 47% of the cases are due to obstruction and infection which constitute the major the cause [4].

Hydrocephalus is not a new condition, and for many years there had been little in the way of new treatments or improved outcomes. That has changed in the last few decades with increasingly sophisticated imaging method, technological innovations in shunt design and placement, expanded role of endoscopy, and a renewed interest in scientific investigation. At the same time, the recognition of the burden of this illness in underdeveloped countries has inspired neurosurgeons to help develop the infrastructure and expertise to treat children with hydrocephalus and other neurosurgical conditions in geographic areas of need [5]. Hydrocephalus, as known as a disease process, is an ancient one. The disorder has described in cave paintings, in early manuscripts in antiquity, and in many clinical observations over the last 25 centuries. The treatment of hydrocephalus as a surgical disorder is very recent, only dating to the 1950s. Prior to this period, treatment surgically lead to the death of the patient in almost one hundred percent of the time. [6]. Hydrocephalus is a central nervous system disorder characterized by excessive accumulation of cerebrospinal fluid (CSF) in the ventricles of the brain. Cognitive and physical handicap can occur as a result of hydrocephalus. The disorder can present at any age as a result of a wide variety of different diseases. The pathophysiology of hydrocephalus is unclear. While circulation theory is widely accepted as a hypothesis for the development of hydrocephalus, there is a lack of adequate proof in clinical situations and in experimental settings. However, there is growing evidence that osmotic gradients are responsible for the water content of the ventricles of the brain, similar to their presence in other water permeable organs in the body[7]. Hydrocephalus can be classified into communicating and non communicating types. Communicating (non obstructive) hydrocephalus occurs when the flow of CSF is blocked after it exits the ventricles. Non communicating (obstructive) hydrocephalus occurs when the flow of CSF is blocked along one or more of the narrow pathways connecting the ventricles [(8)]. Children with hydrocephalus could also be classified as technology dependent, because the majority of children require a permanent shunt to manage the condition. However,a shunt is an internal device, and once inserted does not require ongoing maintenance unless it malfunctions [(8)]. Hemorrhage into the ventricles of the brain is of the most serious complications of preterm birth despite improvements in the survival of preterm infants. Large intraventricular hemorrhage (IVH) has a high risk for neurologic disability, and 50% of these children go on to develop progressive ventricular dilation. Increasing survival of extremely preterm infants is associated with posthemorrhagic ventricular dilation (PHVD) with high morbidity and considerable mortality. Multiple blood clots may obstruct the ventricular system or channels of cerebrospinal fluid (CSF) reabsorption initially but lead to a chronic arachnoiditis of the basal cisterns involving deposition of extracellular matrix proteins in the foramina of the fourth ventricle and the subarachnoid space [(9)]. Hydrocephalus is not a single disease. It is a manifestation of many conditions including congenital malformations, trauma, tumors, infection, and hemorrhage. It is well known that etiology is a significant risk factor for outcome in these children, and therefore clinical investigations require large numbers of children with different forms of hydrocephalus. Basic scientists are now working in a multidisciplinary cooperative way to share expertise in these many areas[10].

Methodology

The aims of the study: (1) Assessing the nurse's practices toward hydrocephalus neonatal baby care. (2) Constructing an educational program for nurse's practices toward hydrocephalus neonatal baby care. (3) Applying the educational program for nurse's practices toward hydrocephalus. (4) Finding the relationships between the nurse's practices toward neonatal with hydrocephalus and socio-demographic characteristics such as (age, gender, level of education training session). (5)Evaluation the effectiveness of an educational program for nurse's practices toward hydrocephalus neonatal baby care

Study Design: A quasi- experimental design with the application of a pre-test/post-test approach is conducted for the period of October 7th October 2018 to 10th April 2019 on nurses working in intensive care units.

Study Sample: Non-probability sampling (purposive sample) are chosen, (30) nurses is selected according to the criteria includes the nurses all educational levels working in intensive care units, nurses have one year or more of experience in intensive care units, and those who agreed to participate in the study.

Study Instrument: The study instrument was constructed depending on literature reviews and previous studies toward hydrocephalus neonatal baby care. It is a questionnaire format for the research purpose and composed of three parts and these parts are:

Part I: Which composed of demographical characteristics.

Part II: This part is related to evaluation of nurse's knowledge toward hydrocephalus neonatal baby care.

Part III: This part is related to evaluation of nurse's practices toward hydrocephalus neonatal baby care.

Data Collection the Method: The data were collected from Neonatal intensive Care unit of the selected hospitals in Medical City. The period for 7th october to 10th April 2019 then post –test data collection immediately after implementation of the program.

Statistical Analysis: The data were analyzed through the application of statistical package for social science IBM-SPSS version 24.0 and by applying of descriptive and inferential statistical tests that are:: Frequencies, Percentages, and mean of score.

Results and Discussion

Table 1 shows that nurses who are working at Neonate Intensive Care Units are Female (100%) with age group range from 20 to 29 years old (79%); with mean age (28.26) regarding educational level in nursing, about two third of sample were having secondary school education (66.6%) while remaining were distributed between diploma (medical institute) and bachelor degree (nursing college) (16.7%). The years of employment in nursing reveal that 66.7% of nurses are working for period of 1-5 years and 20.8% working for period of 6-10 years; for the same period was showing with working in NICU, 70.8% of nurses are working 1-5 years in NICU and 20.8% are working for 6-10 year. Table 2 presents the levels of nurses' knowledge regarding caring of hydrocephalus baby pre, post1, and post2-test prior to educational program; the findings indicate that nurses having poor to fair level of knowledge prior educational program (Pre-test: poor=41.7% and fair=50%), while the level of nurses' knowledge is increased to good after educational program during post-test I and post-test2 (good=100%). Table 3 presents the level of nurses' practices toward caring of hydrocephalus baby; the finding indicate that half of nurses showing fair level of practices during pre-test period (50%) and the remaining were distributed between poor and good practices (25%), while during the post-test I and II, the nurses are showing good practices toward caring of hydrocephalus baby (100%) their engagement in an educational program. Acute hydrocephalus is a life –threatening condition that condition that is usually treatable with prompt surgical intervention. Various alterations in the normal cerebrospinal fluid (csf) dynamics, which result in elevated intracranial pressure. Part I: Nurses their Demographic Characteristics

Results shows that nurses who are working at Neonate Intensive Care Units are Female (100%) with age group range from 20 to 29 years old (79%); with mean age (28.26) These results agree with findings [11-13] . regarding educational level in nursing, about two third of sample were having secondary school education (66.6%) while remaining were distributed between diploma (medical institute) and bachelor degree (nursing college) (16.7%) This outcome agree with[(14)(15)] . The years of employment in nursing reveal that 66.7% of nurses are working for period of 1-5 years and 20.8% working for period of 6-10 years; for the same period was showing with working in NICU, 70.8% of nurses are working 1-5 years in NICU and 20.8% are working for 6-10 year This outcome agree with[(16)] . And this study reveals that 79.2% of nurses are participated in a training session and courses about caring of babies with hydrocephalus and only 20.8% were not participated. The number of training session was ranged between 1-3 sessions (62.5%). All the nurses who participated in such training were inside country (79.2%) This finding agrees with[(17)].

Part II: Levels of Nurses' Knowledge about Hydrocephalus Baby at the pre-post period: Finding indicated the levels of nurses' knowledge regarding caring of hydrocephalus baby pre, post1, and post2-test prior to educational program; the findings indicate that nurses having poor to fair level of knowledge prior educational program (Pre-test: poor=41.7% and fair=50%), while the level of nurses' knowledge is increased to good after educational program during post-test I and post-test2 (good=100%)

Part II: Levels of Nurses' Practices toward Care of Hydrocephalus Baby at the pre-post Period: Finding indicated the level of nurses' practices toward caring of hydrocephalus baby; the finding indicate that half of nurses showing fair level of practices during pre-test period (50%) and the remaining were distributed between poor and good practices (25%), while during the post-test I and II, the nurses are showing good practices toward caring of hydrocephalus baby (100%) their engagement in an educational program.

Table (1): Levels of Nurses' Knowledge about Hydrocephalus Baby at the pre-post period:

Levels of Knowledge	Pre-test				Post-test I				Post-test II			
	F	%	M	SD	F	%	M.S	SD	f	%	M	SD
Poor	10	41.7	1.67	0.637	0	0	3.00	0.000	0	0	3.00	0.000
Fair	13	50			0	0			0	0		
Good	2	8.3			24	100			24	100		
Total	24	100			24	100			24	100		

Table (2): Levels of Nurses' Practices toward Care of Hydrocephalus Baby at the pre-post Period:

Levels of Practices	Pre-test				Post-test I				Post-test II			
	F	%	M.S	SD	F	%	M.S	SD	f	%	M.S	SD
Poor	6	25	2.00	0.722	0	0	3.00	0.000	0	0	3.00	0.000
Fair	12	50			0	0			0	0		
Good	6	25			24	100			24	100		
Total	24	100			24	100			24	100		

Conclusion

There is no significant relationship between nurse's knowledge and practices and nurse's level of education and socio-demographic characteristics and significant relationship between nurse's knowledge and practices and general nurse's employment years and period of working in the Neonatal Intensive Care unit (NICU) . Over all evaluation of educational program for nurse's was fair.

Active Learning Practices for First-Grade Science Teachers and their Relationship to Students' Successful Intelligence

Ban Mohammed Kareem[1], Ghadah Shareef Al-Sheikh[1], Abbas Hussein Mugir[1]

[1]*Department of Higher Education, College of Basic Education, University of Babylon, Babylon, Iraq*

Abstract

The paper aimed to identify the active learning practices of the teachers of science for the first grade and their relation to the successful intelligence of their students. The descriptive approach was used to suit the nature of the study. The researcher presented the study tools to a group of experts and arbitrators for the purpose of verifying the validity of the research tools. The data were also statistically processed using Holistic equation, arithmetic averages, standard deviations, The results of this study found that active learning practices were weak, while successful intelligence was medium. Results showed a statistically significant positive correlation between active learning practices among science teachers and between In the light of the previous results, the researcher recommended several recommendations, including the preparation of training programs for teachers of science in general and for the first grade teachers in particular the average of active learning practices and the need to hold seminars for science teachers to identify successful intelligence and provide a classroom environment that works on development .

Keywords: *Active Learning-Science Teachers-Successful Intelligence.*

Introduction

In view of what the Ministry of Education in Iraq aspires to keep pace with the educational system and the elements of the educational process for the progress made whether in the role of the teacher or the role of the learner through the use of teachers educational practices focused on making the student the focus of the educational process and active-active with the intelligence and abilities The researcher finds the need to reveal the level of active learning practices among the teachers of science and the level of intelligence in their students and the relationship between active learning and successful intelligence. Therefore, the problem of research can be formulated by the question: Is there a correlation between active learning practices The teachers of science and the successful intelligence of their students? The current era has witnessed great development in all aspects of life. We reflect this development in the field of education and teaching method[1]. Moreover, teachers do not care about strategies used with students in learning and accordingly, they follow certain modes of teaching and thinking that encouragesauto-memorization[2]. As education is a social necessity and enjoys a value and importance because it has a practical effect in all societies and educational institutions [3]. There are several modern teaching method and strategies that pay attention to the learners and deem them as the focus of the education process. The education process has been shifted from the dependence on the teacher to dependence on the learner's themselves, with minimal contribution of the teacher as a director in the education process[4]. Modern education has to keep up with the tremendous developments that happened in all aspects of life, so the teacher is no longer just a teacher but a learner of knowledge, the learner has an important role in the process of education and learning, and the teacher became organizer and guide of those processes[5] teachers have to choose method, strategies

Corresponding Author:
Ban Mohammed Karim
Department of Graduate Studies-Method of Teaching General Sciences, Faculty of Basic Education, University of Babylon, Iraq
e-mail: banseriawi@gmail.com.

and teaching method which are intended to reach the aim in educational programs, the selection of these things depend on the suitability of the students' characteristics, needs, the nature of the academic content, educational aims and the available financial and human means[6]. as the use of modern strategies was not accidental, but came in response to the needs of the educational system to achieve its objectives[7]. Hence, teaching concept indicates the intentional and regulated process by which the teaching elements (teacher, learner and material) interact, and which is done according to pre-planned procedures aiming at fulfilling desirable destinations and ends[8]. The process of teaching science is fertile ground in information, facts, concepts, skills and educational values towards the students in the intermediate stage, which may contribute to the improvement of the level of students' achievement in science, but recently showed a lot of educational and scientific data such as previous studies and conferences towards the educational process In the current period, the information technology revolution has started at a rapid and rapid pace in the technological field, which still leaves clear imprints in the lives of individuals and reflects broad challenges in all areas of life. Science has played a major role in change and scientific development. It has brought with it the interest of educationalists and their partners in the hands of innovation, development, and modernization in terms of content, teaching method and teaching aids. In this sense, it is the responsibility of teachers to choose the method, strategies and teaching method intended to achieve the goal to be achieved in programs [1]. Some experts in the field of science teaching believe that the method of teaching the dominant sciences and the sciences, The traditional method is often effective in achieving the goals of science teaching, and effective science education can produce effective independent learners who are able to organize their everyday life, be productive, cooperative and have the ability to make good decisions, [9]. The teacher in general and the science teacher, in particular, should be able to have all the modern method and teaching practices to choose the appropriate educational situation. The successful middle school teacher is especially able to make the student involved in the educational process. Not a passive recipient [10]. This can only be achieved by activating active learning within the classroom, which makes the learner the focus of the learning process, participating in achieving his or her learning goals, making him active in the classroom, practicing experimentation, and conversing with the discussions within him [11]. Which makes the learner the focus of the educational process and makes him an active, active and participatory, has a role in the management of the educational process in terms of identifying some of the activities that address and commensurate with the wishes and potentials, and this type of learning is based on learning by practice and participation and research and exploration, P In the classrooms, today's learners are faced with the problem of teaching them with learning and teaching practices that do not match their mental abilities. This leads to a lack of learning. At the same time, these learners and their teachers may reach the conclusion that They have a lack of learning ability and the fact that many of them have amazing abilities to learn if taught in a way that suits them, and Sternberg believes that this claim was reached only through one case is that the success of many learners in certain circumstances and failure In other circumstances, Sternberg developed the theory of successful intelligence for the order This is done only through the development of a set of teaching and assessment method and practices to help learners reach their maximum potential and success in life [12]. Successful intelligence is one of the key cognitive processes that can outweigh information and knowledge in facilitating the adaptation and uncontroled of individual resources and resources within the context of the learner in different life situations, whether these resources are in the form of information, experiences or tools available in the learner's daily life situation[13]. The learner's ability to achieve the goals according to certain criteria or special within the social and cultural context in which the learner, that is, the learner sets goals and works to achieve them in line with the social and cultural context, which is the ability to achieve success in life by the expression of personal standards within the social context, The intellectual of the learner and consists of successful intelligence (analytical intelligence, practical intelligence, and creative intelligence). [14] There are previous studies similar to the current research variables: Al-Rawashdah and Walid (2015). The degree of active learning practice in science classes in the primary classroom in the North Eastern Bedouin schools in Jordan. And the study (happiness and Dalal) 2018 Degree of the practice of primary school teachers of active learning elements from the point of view of mentors and managers in Kuwait City. And Ahmed, Nahla (2016). The relationship between the intelligence of three-dimensional and mental alertness among middle school students. The study (Zoubi, Ahmed) 2016 The relationship between the assessment of successful

intelligence and its practice in the education of private school teachers Jordan.

Methodology

The researcher used the descriptive (associative) approach as the appropriate method for the purpose of research aimed at identifying the active learning practices of the first-grade middle school teachers and their relation to the successful intelligence of their students. The sample of the research was randomly selected by 13% of the research community. The sample of the teachers was 15 teachers and the sample was 42% of the research community. (1691) Students for the purpose of collecting data To answer the study questions and achieve their objectives, the researcher prepared a note card to observe the active learning practices after reviewing the previous studies and literature concerning active learning if the observation card consisted of (40) Which includes (9) paragraph and field (implementation), which includes (23) paragraph and area (calendar) (High, high, medium, low, very low). The researcher presented a note of active learning practices in their initial form on a group of teachers specialized in the field of teaching method and the quality of education in various Iraqi universities to express their views on the clarity and integrity of its formulation and has been modified in accordance with their observations. The researcher also prepared a successful intelligence test to measure the successful intelligence of first-grade students. The Sternberg test, which was prepared for the secondary stage, consisted of (36) multi-choice questions on the three abilities of successful intelligence (analytical ability, practical ability, creative ability) With (10,14,12) question, respectively, the researcher presented the test with instructions to a group of professors specialized in teaching method in different Iraqi universities and according to the opinions and observations, the researcher modified the test.

Conclusion

The results showed a positive correlative relationship at the level of significance between the active learning practices of the science teachers and the successful intelligence of their students Pearson correlation coefficient (0.67).

Study of School Safety Climate: Case of Elementary Schools in Beji District–Depok 2018

B. Adiyantoko[1], M. Tejamaya[1]

[1]Department of Occupational Health and Safety, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Creating a positive school climate with safety being assured is vital to assist students accomplishing their expected results. More than 2,000 children and adolescents die every day as a result of accidents [20]. About 40% of children who died because of injuries aged between 1 to 14 years old [21]. This is the first study on elementary school safety climate in Indonesia. Employing the descriptive analytics approach with cross sectional research design, the study examine the school safety climate in Indonesia. We distributed questionnaire to the principal, teachers, school staff and students. The data of accidents was obtained by interviewing the principal or teacher. The results showed that the safety climate in a Primary School in Beji, Depok in 2018 had a good category. The Islamic Private Elementary School received scored higher than MI/ MIS Private Primary Schools and State Primary Schools. The highest accident data occurred due to falling. Factors that improve the safety climate are management commitment, a comfortable school environment, adequate facilities, and sufficient numbers of teachers.

Keywords: *Cross Sectional, Safety Climate, Accidents, Elementary School.*

Introduction

Creating a positive school climate with safety being assured is vital to assist students accomplish their expected results. It will create a positive relationships between school citizens, and a safe physical environment.

Elementary school children are characterized with activities which involve moving, and working in groups. This increases their chance to face accidents and illness at school. An accident occurred in October 2017 at Yos Sudarso Batam Elementary School. The student was hit by a goalpost while climbing a pole[1]. Another case occurred to a student of Harapan Utama Batam Elementary School due to a fall in the football goalpost which led to the death of the student[1].

Depok City Population and Civil Registration Service recorded an increase in the population of 47,133 people during 2016. Based on Depok education data year 2012/2013, the number of primary schools in Beji Sub district is 25 Public Elementary Schools and 10 Private Elementary Schools (Depok City Education Office, 2013). This affects the health profile of children in Depok City. The Depok City Health Office determined the status of extraordinary events in cases of food poisoning which affected 27 children[2]. We expect to gain perspectives about the existing safety system and what needs to be improved. This research aims to investigate the school safety climate in the case of elementary school in Beji District, Depok.

Method

The data was collected by distributing questionnaires and conducting interviews with 13 principals, 179 teachers, 11 staffs and 147 students from 7 public

Corresponding Author:
M. Tejamaya
Department of Occupational Health and Safety, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia
e-mail: tejamaya@ui.ac.id

elementary schools and 7 private elementary schools (n = 350). The private schools consist of 4 Islamic schools and 3 general elementary schools. We provided guidance to fill out the questionnaire.

This study uses the descriptive analytics approach with cross sectional research design. We distributed questionnaire to the school principal, teachers, staff and students to obtain primary data. Secondary data was obtained through interview and observation.

The primary data in discussion is the characteristics of respondents which were discovered through the questionnaires developed by NORDIC (NOSACQ-50), namely the assessment of workers' perceptions of 1) safety management commitment and capabilities, 2) empowerment of safety management, 3) safety management justice, 4) Workers 'commitment to work safety, 5) Priority of workers' safety and no tolerance of hazard risk, 6) Learning, communication and trust and 7) trust in the effectiveness of the work safety system.

Secondary data referred to data based on interviews with principals, teachers or school staffs, and based on records of accidents and illnesses within a certain period.

Results and Discussions

From a total of 203 teacher respondents, the average score of safety climate dimension ranged between 3.20 and 3.47 with a standard deviation ranging from 0.21 to 0.43 (Table 1). The result demonstrates that all schools are deemed having an adequate safety climate. of all seven dimensions, the workers; commitment to environmental safety obtained the highest average score (3.47). The lowest average score was held by the empowerment of safety management dimension (Table 1).

Table 1: Overview of Teacher's Safety Climate at Beji District Elementary School, Depok

Variables	Mean	SD	95% CI	n
Safety Management Commitment and Capabilities	3,31	0,27	3,27-3,35	203
Empowerment of Safety Management	3,20	0,43	3,14-3,26	203
Safety Management Justice	3,23	0,38	3,19-3,29	203
Workers' Commitment to Work Safety	3,47	0,32	3,42-3,51	203
Priority of Workers' Safety and No Tolerance of Hazard Risk	3,24	0,21	3,21-3,27	203
Learning, Communication and Trust	3,25	0,33	3,19-3,29	203
Trust in the Effectiveness of the work safety system	3,29	0,38	3,24-3,35	203

Of the 147 student respondents, the average score of the safety climate dimension ranged from 3.34 to 3.69 with a standard deviation ranging from 0.33 to 0.62 (Table 2). Equivalent to the results from teacher respondents, that students at elementary schools in Beji, Depok considered schools to have an adequate safety climate. The highest and lowest average scores were obtained by the safety management justice dimension (3.69) and empowerment of safety management dimension (3.34) (Table 2).

Table 2: Overview of Students Safety Climate in Elementary Schools in Beji, Depok in 2018

Variables	Mean	SD	95% CI	n
Safety Management Commitment and Capabilities	3,57	0,55	3,48-3,66	147
Empowerment of Safety Management	3,34	0,50	3,26-3,42	147
Safety Management Justice	3,69	0,33	3,63-3,74	147
Workers' Commitment to Work Safety	3,57	0,52	3,49-3,66	147
Priority of Workers' Safety and No Tolerance of Hazard Risk	3,62	0,62	3,52-3,72	147
Learning, Communication and Trust	3,39	0,43	3,33-3,47	147
Trust in the Effectiveness of the work safety system	3,37	0,48	3,29-3,45	147

The results of this study is analogous to a study by Griffin (2000)[3], which found that safety climate is positively correlated with safety performance. Several studies have evaluated the relationship of safety climate to safety outcomes ranging from unsafe behavior[4]. safety behavior[5-7], risk perception[8], near misses[9], safety violations and motivation[10], and accident rates[11]. A positive safety climate is able to create work environment where improvements in safety performance can continue to be achieved[12].

Students face a high risk of accidents, and illness at school, because of the environment, and inadequate quality of the school facilities. Lack of teacher supervision due to the shortage of academics worsen the problem.

Dimension 1: Safety Management Commitment and Capabilities

This dimension captures the perceptions on the way school management prioritizes safety.

The safety management commitment and capabilities of the school were sufficient, proven by the average score of 3.42. It is known that the sub-dimension 'pays no attention to when a worker ignores safety' (A3) acquired the highest score. Meanwhile, the sub-dimension 'we who work here believe in the ability of the school management to handle safety' (A6) obtained the lowest score.

The principal's behavior can determine the workers' level of perception of safety management commitment[10]. Management support is one of the strongest contributions in shaping safety climate perceptions[11].

Based on observation and interview, the schools' safety management commitment, especially in Public and Islamic schools, were limited. Many buildings and facilities went unnoticed (e.g. no stairs handrail, ceilings that might have fallen, fire extinguishers unavailability). Private schools were found to have considered safety, such as providing pedestrians' signs, evacuation direction, and clinics.

Dimension 2: Empowerment of Safety Management

The dimension captures the perceptions concerning the school management's actions on gathering all stakeholders to participate in safety management. Employees', involvement means empowering the employees, which in this case is school citizen, to be involved in work and safety processes[13].

Management safety empowerment is entrustment from management concerning workers' ability and judgment about safety[22]. School citizens involvement can improve safety conditions, such as reporting injuries and dangerous situations[14].

According to our observations and interviews, the school management has not considered safety in the school policy. Their priorities is students' academic achievement. School visits to accommodate the school aspirations have also not been realized.

Dimension 3: Safety Management Justice

This dimension captures the perceptions on how the school management treat those who are in danger.

The employees have positive perceptions about the management justice on school safety. The sub-dimension "Management always blame the employees when an accident occurs" (A21) obtained the highest score and the sub-dimension "Management looks for the cause of the accident and not the guilty (A20) acquired the lowest score. The items that need to be strengthened are "the perception of school principal, teachers, staff and students about how the management investigates the people who encounter an accident (A19), "the management's treatment towards the employees who are injured" (A21, A22), and "the way of finding the cause of accidents" (A20). It is imperative for the school management to find the root cause of the accidents by using the 5W tool in order to help them determine the corrective action.

Based on observations and interviews, when an accident occurs, the school management inquired the students. However, the school have not carried out in-depth observation. Accident events are only reported to student guardians, but there have been no reports on management. To mitigate this, the school needs to produce a central reporting system.

Dimension 4: Workers' Commitment to Work Safety

This dimension captures the perceptions of workers about their involvement on work safety and whether they show high commitment to work safety, are actively promoting work safety and care about others' safety.

Andriessen (2011) found that safety motivation was not only determined by the leadership factors, but also by group intimacy[10]. Therefore, the commitment of teachers, staff and students is important to determine the perceptions within the school.

Based on observations and interviews, they always maintain student safety to the maximum extent. Teachers share their experience with other teachers about events that occur at school. This can be used to increase awareness about safety. Lack of teachers as educators and supervisors becomes obstacle, because permanent teachers in elementary schools is limited, and the teaching process is assisted by honorarium teachers.

Dimension 5: Priority of Workers' Safety and No Tolerance of Hazard Risk

This dimension captures the workers' perception about their involvement on school safety and whether they prioritize it over work targets, and avoid risky conditions. The perceptions of school citizens about risks can influence risky behavior in teaching and learning activities[15]. The results showed that the dimension "priority of workers' safety and no tolerance of hazard risk" achieved the required score. The overall average score of this dimension is 3.31, with the average score of teachers and students are 3.24 and 3.62, respectively. "We consider harmful risks as unavoidable instruments in the work place" (A29) is a sub-dimension with the highest score. Meanwhile, the sub-dimension "we consider minor accidents as part of our daily work (A30) received the lowest score

Our observations and interviews reveal that the school's stakeholders' perceptions about safety is still low. The sign of the low perceptions of safety can be seen from the buildings of several public schools which were damage but still being used. They prioritized the school main function as a place of learning and teaching but ignoring safety aspect. The teachers said that accidents such as bumping, slipping and falling are normal.

Dimension 6: Learning, Communication and Trust

This dimension examines the perceptions of teachers, staff and students about how they relate to safety in the workplace in terms of discussing safety issues, learning from work experience, helping one another to work safely to ensure safety. Individual learning processes plays a key role in the process of improving safety[16]. A large body of literatures state that communication is often regarded as a supporting factor in a positive safety climate[17,18,11,13].

Among the measures that can be taken is that the school can use the available technology, such as e-mail, WhatsApp, and text message to report the accident. The communication must involve not only the interaction between management and workers, but also among workers. Workers who have a safety interaction with their coworkers tend to have a more favorable safety perception[15].

Dimension 7: Trust in the Effectiveness of Work Safety System

This dimension captures the perceptions of teachers, staff and students about the effectiveness of work safety systems run by safety officers, safety representatives, or teachers who have a specific task to deal with safety and health in schools. Zohar (2000) argue that on defining the dimensions of the school safety climate, several aspects of the safety management system must be identified, namely the position of safety officers, the frequency of safety checks, and the emphasis on safety training[19].

Based on observations and interviews with school principals or teachers, the Public Elementary Schools and Islamic Schools have not acquired appropriate safety system. Meanwhile, the Private Primary School is already one step forward. However, the private school still does not have a safety officer. Similarly, training on emergency response has not been executed. Schools should raise the awareness of the importance of safety officers, safety audits, and risk assessment in preventing accidents.

Conclusions

Based on our study on investigating the school safety climate with reference to the NOSAC-50 safety climate questionnaire in Elementary Schools in Beji District, Depok in 2018, we found the following evidence:

a. The dimension "Safety management commitment and capabilities" are proven to be "adequate". However, several issues need to be refined on the management side, to ensure that safety issues are handled correctly.

b. The dimension "Empowerment of Safety Management" is in the good category. Although this is good, employees' perception of management in

relation to the involvement of employees in decision making must be improved.

c. The dimension "Safety Management Justice" conducted by teachers and students are proven to be adequate. Yet, there are cases when teachers are afraid to report accidents due to the sanctions.

d. The dimension "Workers' Commitment to Work Safety" is in the good category. However, a minor improvement is needed, especially in workers' perceptions regarding the handling of hazards and teachers' effort to achieve a high level of work safety.

e. The dimensions "Priority of Workers' Safety and No Tolerance of Hazard Risk" in teachers and students are in the good category. However, based on the observation and interviews, there was still a lack of discussion about safety-related issues in schools.

f. The dimension of "Learning, Communication and Innovation" is in the good category. However, based on the observation and interviews, the importance of the teachers and staff assumption about clear safety goals and training need to be improved.

g. The dimension "Trust in the Effectiveness of the work safety system" of teachers and students are in the sufficient category. However, based on the observation and interviews, it is necessary to improve teachers and students' perceptions about the function of safety officers, safety audits, and risk assessment.

Effectiveness of an Instructional Program on Patient's Knowledge Regarding Secondary Prevention of Coronary Artery Diseases in Al Nasiriyah Heart Center

Zainab Raheem Lafta[1], Khalida Mohammed Khudur[2]

[1]MSc Student, University of Baghdad, College of Nursing, Iraq,
[2]Assist. Professor, Adult Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Secondary prevention of coronary artery disease by comprehensive risk factor modification reduces mortality, decreases subsequent cardiac events, and improves quality of life. Objective: To assess effectiveness of the instructional program on patient's knowledge regarding secondary prevention coronary artery diseases. A quasi-experimental design (two-group pretest-posttest) was used conducted in this. The present study was carried out at Al- Nasiriyah Heart Center in Thi-Qar Governorate for the period 17th of October 2018 to 6th of April 2019. A non-probability (purposive) sample of (40) patients were selected questionnaire for knowledge was constructed for the purpose of the study. Validity and reliability of the instrument were determined through a pilot study. Data were analyzed through the use of Statistical package for Social Sciences (SPSS) version. Descriptive and inferential statistical measures were employed. The study indicated that the knowledge scores of participants were inadequate for both groups in the pre-test, but the study group knowledge scores have increased after introducing them the instructional program. Therefore, there were significant differences between both groups. But the results indicated that there was no relationship with statistical significance between patient knowledge and demographic data.

Keywords: *Coronary artery diseases, secondary prevention.*

Introduction

Coronary artery disease (CAD) also known as coronary heart disease (CHD), coronary atherosclerosis and Ischemic heart disease (IHD), which is a most common type of heart disease, and it represents a major source of morbidity and mortality in developed countries [1]. CAD is results from atherosclerosis, or the accumulation of fatty plaques in artery wall that cause narrowing of the artery lumen. CAD that includes coronary syndrome, atherosclerosis, and other form of chronic ischemic disease, is responsible for many deaths. Chest pain, shortness of breath, heart attack or other syndromes can be caused by a blood clot or plaque rupture that blocks a narrowed artery leading to heart [2]. As a result, the heart muscle can't get the blood or oxygen it needs. This can lead to chest pain (angina) or a heart attack. Over time, CAD can also weaken the heart muscle and contribute to heart failure and arrhythmias[3]. CAD is usually associated with one or more risk factors. Several aspects of the association between a potential risk factor and the disease are evaluated before an association is considered causal [(4)]. The majority of these risk factors can be controlled or modified. The modifiable risk factors include sedentary lifestyle, rich fatty diet, smoking, obesity, high alcohol intake, poor stress management, social isolation and medical conditions such as diabetes and hypertension. Non-modifiable risk factors include increasing age, gender and heredity. Globally 80% to 90% of people dying from CAD have one or more major risk factors that are influenced by life style [5]. The death rates from CAD vary

Corresponding Author:
Zainab Raheem Lafta
MSc Student, University of Baghdad, College of Nursing, Iraq

with age, gender, socioeconomic status [6]. The guidelines for prevention of heart disease by the American Heart Association target the risk factors that have the potential for change. Educating patients on cessation of smoking, dietary changes, controlling hypertension, maintaining weight, and diabetes can decrease their risk of (CAD). [7]. Knowledge of the predisposing risk factors is important. One method of targeting preventive educational strategies involves measuring and appropriately disseminating knowledge of the modifiable risk factors. Earlier studies have revealed that education programs for the elderly were effective in improving health promotion knowledge and behaviors[8]. Secondary prevention of Coronary artery disease by comprehensive risk factor modification reduces mortality, decreases subsequent cardiac events, and improves quality of life. Secondary prevention includes medical therapy and surgical revascularization in the form of coronary artery bypass grafting or percutaneous coronary intervention. Medical therapy focuses on comprehensive risk factor modification [9].

Methodology

A quasi-experimental design was carried out at Al- Nasiriyah Heart Center in Thi-Qar Governorate from 17th of October 2018 to 6th of April 2019. The sample involved All these patients who are inpatients at Al- Nassiriyah Heart Center which is divided into two groups, one is study group (40) patients and one is control group (40) patients. A randomized sample (80) patients was selected through probability sampling technique.

The instrument that used is the questionnaire which is composed of (35) multiple choice question regarding patients′ knowledge. Reliability of knowledge was determined through collecting the data from 10 patients and performing test and re-test, the reliability coefficient results are significant for knowledge and validity of questionnaire was determined through the experts.

Results and Discusion

Weak relationships are a proved in light of (SDCv.), since no significant relationships were accounted at P>0.05, and according to that, it could be concluding that studied questionnaire of patient's knowledge improvements could be generalizes on studied population even though differences within their socio-demographical characteristics variables of studied subjects in the study group. With respect to age group, the study finding revealed that the majority of study group patients were more than 50-years and they are accounted 26(65%), and 30(75%) at the study and controlled groups respectively. This study agrees with Qasim, 2017 which indicated that majority of sample are 45(56.25%) between (50 – more) age group [10]. Regarding of gender, the study finding revealed that majority in the study group were males while male patients were recorded slightly increased than female and they are accounted 26(65%), and 22(55%) at the study and controlled groups respectively. This study is supported by Sobhi,2011 who stated that they are accounted (76.2%) the males were more [11].In relation to educational status, the study finding displayed that majority of study group patients were Half of studied patients has low educated levels (Illiterate, and Primary School). This study was supported by Al- Jubori,2012 who reported that degree the majority of patients low educated levels [12].Concerning to occupational status the study finding displayed that majority of study group patients were Government Employee, and House wife. This study was supported by Al-Jubori, 2012 who reported that Government Employee, and House wife the majority of patients [12].Regarding Marital status, the study finding most patients were married, and they are accounted 33(82.5%) in each group. This finding was supported by Ali, 2015 who reported that the majority patients married[13]. Statistically significant difference

for patients' knowledge of secondary Prevention of Coronary Artery Diseases (pre – post) periods through implementation of instructional program for study group. This finding indicates the positive influence of the instructional program in improvement patients' knowledge. This finding is supported by EbyKorah (2016) who reported that increased influence of participant's knowledge regarding related to Prevention of Coronary Artery Diseases [3]. The overall assessment of patient's knowledge regarding secondary prevention CAD in the posttest time, there was a fluctuant high assessment of the participants' knowledge with a statistically significant difference in participants' knowledge about secondary prevention of CAD. This finding showed that application of the instructional program was significantly effective in improving knowledge among participants. This study is supported by Korah, 2016who reported that increased participant's knowledge regarding related to Prevention of Coronary Artery Diseases [3]. weak relationships are a proved in light of (SDCv.), since no significant relationships were accounted at P>0.05, and according to that, it could be concluding that studied questionnaire of patient's knowledge improvements could be generalizes on studied population even though differences within their socio-demographical characteristics variables of studied subjects in the study group.This study is supported by Korah (2016) who reported that there were no significant differences between Patients' Knowledge and Socio-demographic Characteristics variables [3].

Conclusion

The instructional program was effective in enhancing patient's knowledge related to secondary prevention of CAD (for all subdomains and the overall).

Financial Disclosure: There is no financial disclosure.

Detection of Vulnerable Periods of Cerebral Desaturation Assessed by In-Vivo Optical Spectroscopy (INVOS) During Superior Cavopulmonary Shunt Operation and Their Effect on Early Postoperative Neurological Outcome

Ashraf Mostafa Abd Raboh[1], Tarek Salah El Din Abd Allah Rezk[1], Samy Amin[1], Ihab Mohamed Salah Eldin Mahmoud Elsharkawy[1]

[1]*Cardiothoracic Surgery Department, Faculty of Medicine, Cairo University, Cairo, Egypt*

Abstract

Background: Postoperative neurocognitive dysfunction is common after Glenn operation. Cerebral oxygen saturation (rSO2) can be assessed by INVOS™ oximeter (Somanetics). We investigated the intraoperative events most associated with cerebral desaturation and the correlation between intraoperative rSO2 and early postoperative neurological outcome in a prospective observational study. Method: thirty patients with single ventricle physiology undergoing elective (Glenn) operation underwent intraoperative rSO2 assessment, including detection of vulnerable periods during which cerebral desaturation occurs, measurements of mean tissue oxygen saturation and area under the curve (AUC), which is the cumulative saturation below threshold. Postoperative neurologic outcome was assessed using the modified Glasgow coma scale for infants and children, and the occurrence of fits and its correlation to the AUC.

Results: Vulnerable periods of cerebral desaturation as detected by INVOS included induction of anesthesia, cannulation and decannulation when the procedure was performed on bypass, and SVC clamping period when the procedure was performed off-bypass, and in cases which used the temporary cavoatrial shunt there was also drop in rSO2 during SVC cannulation. Patients with drop of AUC more than 25% of the baseline had an increased risk of developing postoperative fits.

Conclusions: Intraoperative cerebral desaturation is significantly associated with increased risk of postoperative fits..

Keywords: *INVOS; Glenn; neurological outcome; superior cavopulmonary anastomosis; BDG.*

Introduction

Neurological complications are common after cardiac surgery. Risk factors identified. Include CPB, embolic events, hypoperfusion and cerebral desaturation[1]. It is crucial to study the risk factors and specify their correlation to the neurocognitive outcome, specify measures and practices to prevent or decrease their effect on the neurological outcome. In our study, we assessed the cerebral oxygen saturation (rSO2) during (Glenn), to detect periods of desaturation, and their effect on the postoperative neurocognitive outcome.

Method

Patients: This study was approved by the Cairo University Faculty of Medicine. Institutional Review Board, and patients were enrolled after a signed informed consent was obtained from parents. The study was performed at the Children University Pediatric Hospital,

which is affiliated to Cairo University Hospitals. The study was prospective, observational study with thirty consecutive patients, who were candidates for Glenn operation. Patients were non-randomized into two patient cohorts. Group A underwent the procedure using cardiopulmonary bypass (n=15), and group B underwent the procedure without cardiopulmonary bypass (with or without cavoatrial shunt) (n=15). Patients were excluded preoperatively for preexisting neurological insult, having previous cardiac surgical procedure, abnormal neurocognitive testing, abnormal blood or coagulation profile.

Surgical Procedure: All were done via median sternotomy. For patients who underwent the procedure using CPB, Blood flow was adjusted to maintain temperature-adjusted flow and to maintain acceptable perfusion pressure and arterial oxygen saturation. cardiac arrest was achieved when reconstruction of pulmonary artery, or septectomy was planned.

In-Vivo Optical Spectroscopy: The INVOS™ oximeter (Somanetics), which provides continuous, noninvasive and real time measurement of cerebral oxygenation, is used in this study through adhesive pads applied over the frontal lobes. The near-infrared wavelengths are generated by a light source of the sensor and penetrate skin and bone. Within the brain tissue in 3 cm depth the light is either absorbed or reflected to the two detectors of the sensor. The continuous measured data are displayed on the monitor with an update every five seconds. Area under curve (AUC) account for both depth and duration of desaturation below these thresholds so they are expressed as min% values. If values of AUC from the left and right sides of the brain were different, we took the greater AUC value as relevant. The INVOS™ was applied to patients just before the induction of anesthesia.

Neurocognitive Assessment: Patients assessed preoperatively and prior to discharge, for any neurological deficits; like stroke and seizures, followed by evaluation using the modified Glasgow coma scale for infants and children.

Results

Demographic data: (table 1)

Age: group A; was in the range of 7.5 to 60 months. For group B; was in the range of 5 to 144 months. The difference was statistically insignificant (P value > 0.05).

Weight: group A; was (9.813 ± 3.0764 kg), in the range of 5.1 to 14 kg. For group B; was (10.92 ± 7.4759 kg), in the range of 4.5 to 30 kg. The difference was statistically insignificant (P value > 0.05).

Preoperative INVOS reading: For group A; was (49.53± 13.043 %), in the range of 23 to 73 %. For group B; was (47.87 ± 10.723 %), in the range of 23 to 63 %. The difference was statistically insignificant (P value > 0.05).

Superior vena cava clamp time: For group A; was (16.53 ± 4.58 minutes), in the range of 13 and 30 minutes. For group B; was (14.8 ± 7.36 minutes), in the range of 0 and 30 minutes. There difference was statistically insignificant (P value > 0.05). figure (1)

In group A: the critical threshold: rSO2 < 40 OR 25% change of rSO2 from baseline was encountered during induction of anesthesia and during cannulation prior to cardiopulmonary bypass, figures (2,3).

Table (1): Preoperative results in both groups.

	Group A	Group B	P value
Age	Median 24 m Range 7.5 - 60	Median 12 m Range 5 - 144	> 0.05
Weight	9.813 ± 3.0764	10.92 ± 7.4759	> 0.05
Preoperative O2 saturation	72.33 ± 10.349	70 ± 10.468	> 0.05
Preoperative Hb	14.553 ± 2.3055	14.093 ± 2.1848	> 0.05
Preoperative CVP	9.8 ± 1.612	10± 2.535	>0.05
Preoperative INVOS reading	49.53± 13.043	47.87 ± 10.723	> 0.05

Figure (1): Graph of mean SVC clamp/snare time in both groups.

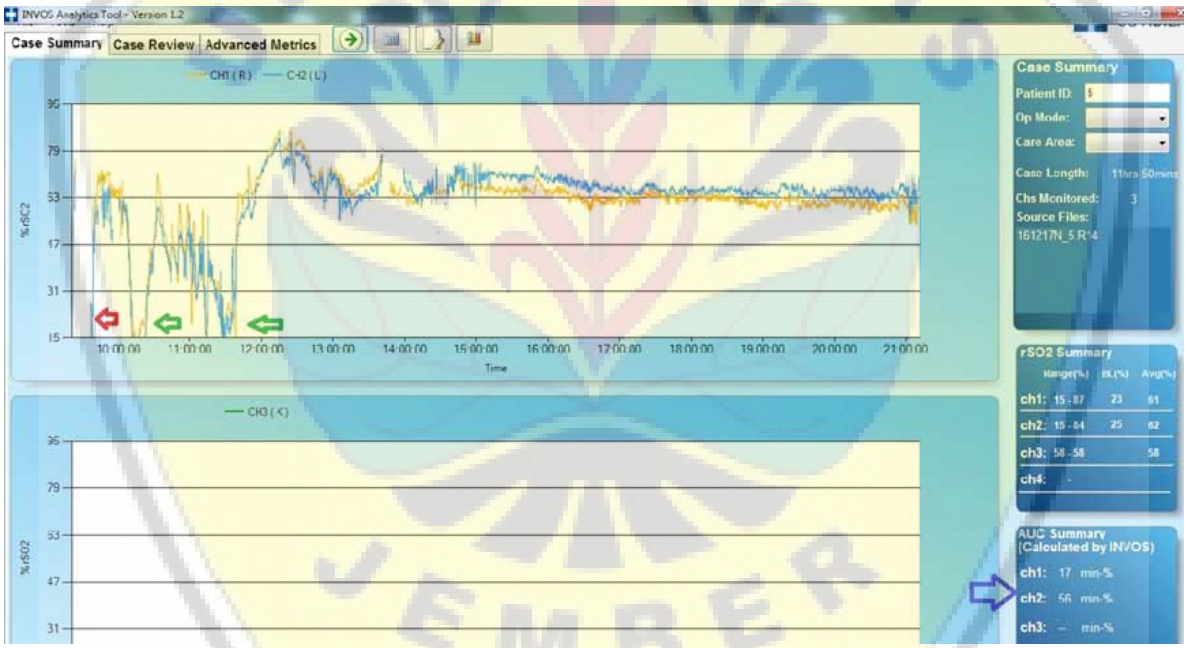

Figure (2) shows an INVOS curve for a patient underwent Glenn shunt using CPB (group A), the blue and orange curves represents ch1 and ch2 the two cerebral leads, the x-axis represents time and y-axis represents rSO2, the red arrow points to drop of rSO2 during induction of anesthesia, the green arrows point to drop of rSO2 during cannulation and decannulation stages of CPB, the blue arrow points to AUC calculated by INVOS (cumulative saturation below threshold).

In group B: the critical threshold was encountered during induction of anesthesia and during SVC clamping period; the latter's effect on the curve was less when a cavoatrial shunt was used (2 cases from the 15 cases done without using CPB), figures (4,5)

NVOS reading after Glenn shunt: For group A; was (71.07 ± 8.614 %), in the range of 48 to 80%. For group B; was (63.67 ± 15.136 %), in the range of 56 to 83 %. The difference was statistically insignificant (P value > 0.05), (figure 6).

Figure (3) shows an INVOS curve for another patient underwent Glenn shunt using CPB (group A), the blue and orange curves represents ch1 and ch2 the two cerebral leads, the x-axis represents time and y-axis represents rSO2, the red arrow points to drop of rSO2 during induction of anesthesia, the green arrows point to drop of rSO2 during cannulation and decannulation stages of CPB, the blue arrow points to AUC calculated by INVOS (cumulative saturation below threshold), in this case it was noticed that during cannulation and decannulation there was less drop in rSO2 and also AUC was less than the former case.

Figure (4) shows an INVOS curve for a patient underwent Glenn shunt without using CPB (group B), the blue and orange curves represents ch1 and ch2 the two cerebral leads, the x-axis represents time and y-axis represents rSO2, the red arrow points to drop of rSO2 during induction of anesthesia, the green arrow points to drop of rSO2 during applying the SVC clamp making a plateau in the curve corresponding to SVC clamp time affecting the AUC (cumulative saturation below threshold), the blue arrow points to AUC calculated by INVOS.

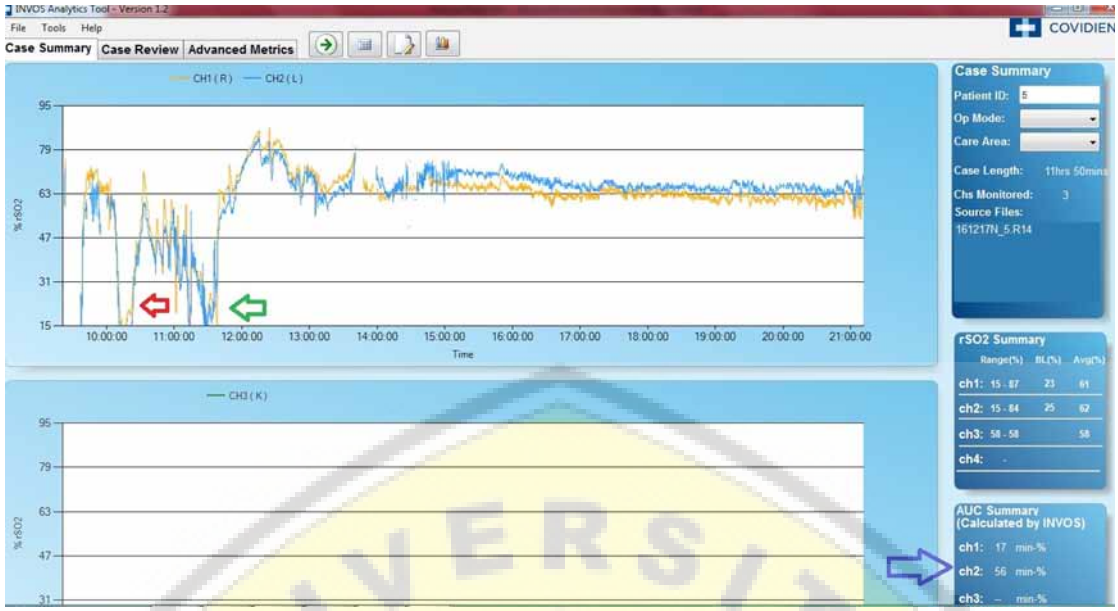

Figure (5) shows an INVOS curve for a patient underwent Glenn shunt without using CPB with cavo-atrial shunt (group B), the blue and orange curves represents ch1 and ch2 the two cerebral leads, the x-axis represents time and y-axis represents rSO2, the red arrow points to drop of rSO2 during induction of anesthesia, the green arrow points to drop of rSO2 during cannulation of SVC avoiding the plateau in the curve corresponding to SVC clamp time with less drop in rSO2 and less effect on the AUC, the blue arrow points to AUC calculated by INVOS (cumulative saturation below threshold).

Area under the curve AUC: The range of AUC for all patients was (0 - 1554 min %) with median 266.5 min%, for group A; AUC was in the range of 12 to 1554 min% with median 128 min%. For group B; it was in the range of 0 to 1419 min% with median 299 min%. The wide range is due unequally distributed data, (figure 7 A & B).

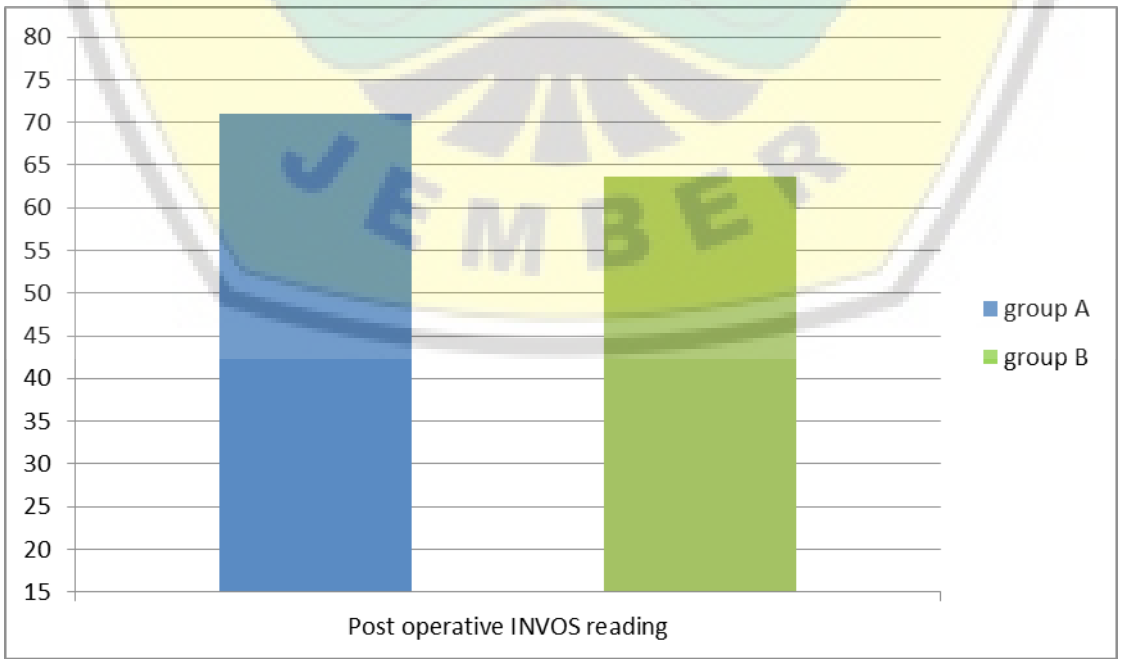

Figure (6): Graph of mean INVOS reading after glenn shunt in both groups.

Figure (7-A): Graph of median AUC in both groups.

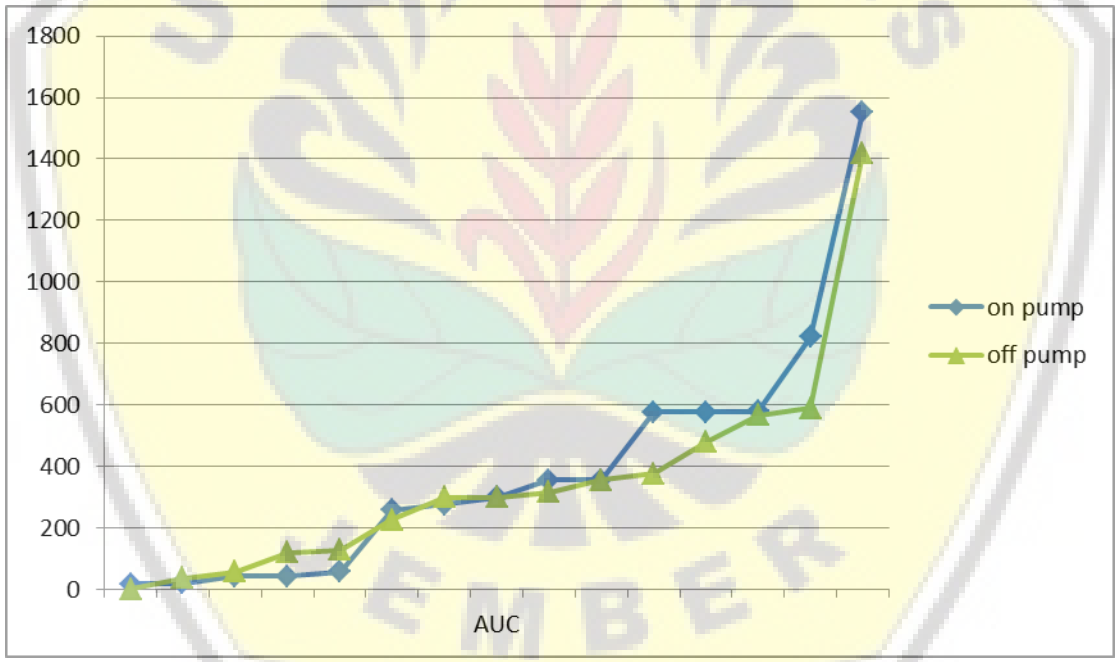

Figure (7-B): Graph of AUC values of patients in both groups.

All patients of group A (100%) had AUC (drop of rSO2 more than 25% of baseline) in their records. *In group B only one patient (6%) had zero AUC (area under the curve) which means that there was no drop of rSO2 more than 25% of baseline while other patients of the same group (94%) had AUC (drop of rSO2 more than 25% of baseline) in their records.

In group B, cavo-atrial shunt was used in two patients, with AUC recorded in one patient 56 min % and 127 min% in the other.

Mechanical Ventilation Time: For Group A; it was in the range of 6 and 72 hours with median 6 hours. For Group B; it was in the range of 5 and 48 hours with median 6 hours. The difference was statistically insignificant (P value > 0.05)

INVOS reading after extubation: For group A; it was (72.13 ± 7.444 %), in the range of 52 to 80%. For group B; it was (69.87 ± 7.15 %), in the range of 56 to 83 %. The difference was statistically insignificant (P value > 0.05).

Neurocognitive Outcome: (table 2): Postoperative neurocognitive outcome was satisfactory regarding both groups, there were no patients with major neurological insults, and there were no patients with delayed recovery. All patients were evaluated to have 15/15 on modified Glasgow coma scale for infants and children.

Postoperative fits: Out of 30 patients included in the study, only 5 patients experienced fits (16.7%), 2 patients from group A (13%) and 3 Patients from group B (20%). The difference was statistically insignificant (P Value > 0.05).

There was moderate correlation between AUC (cumulative saturation below threshold) and neurological outcome (in the form of occurrence of post-operative fits) with significant P value of 0.01, and a correlation coefficient of 0.46.

Table (2): INVOS readings in patients who had postoperative fits.

Patients who had fits	Group A P1	Group A P2	Group B P1	Group B P2	Group B P3
INVOS baseline	48	53	49	43	54
AUC	576	576	588	566	316
INVOS after glenn shunt	80	64	70	56	69
No. of attacks	3 Attacks	Once	3 Attacks	2 Attacks	2 Attacks

Morbidity and Mortality: One patient died due to failure of extubation and sepsis due bilateral phrenic injury (from group A). Another patient died due to low cardiac output (from group B).

The total mortality was 2 patients (6%). The difference was statistically insignificant (P Value > 0.05).

Intensive Care Unit Stay: For Group A; it was in the range of 2 and 37 days with median 6 days. For Group B; it was in the range of 2 and 43 days with median 6 days. The difference was statistically insignificant (P value > 0.05).

Hospital Stay: For Group A; it was in the range of 2 and 38 days with median 7 days. For Group B; it was in the range of 5 and 44 days with median 7 days. The difference was statistically insignificant (P value > 0.05).

Discussion

In our study, we used INVOS oximeter (Somanetics), so that we can identify the vulnerable intraoperative periods with cerebral desaturation below the critical threshold (rSO2 < 40% or 25% decrease of rSO2 below baseline); and the correlation between cerebral desaturation and postoperative neurocognitive outcome.

Cerebral desaturation was expressed as the cumulative area of the saturation curve; below the critical threshold. It is calculated by INVOS, and referred to as the area under curve (AUC). And we observed this for patients undergoing Glenn procedure both on pump and off pump.

In group A: cerebral desaturation was encountered during induction of anesthesia and during cannulation prior to cardiopulmonary bypass. While in group B, it was encountered during induction of anesthesia and during SVC clamping period; the latter's effect on the curve was less when a cavoatrial shunt was used (2 cases from the 15 cases done without using CPB).

As regard monitoring of cerebral oxygenation, In a study performed by Jinfen et al.[2], using near-infrared spectroscopy, they observed that the oxyhemoglobin in brain tissue decreased significantly as SVC pressure increased during clamping of the SVC, the oxyhemoglobin in brain tissue recovered to the preclamping level soon after the SVC was opened, and

it improved continually as the So2 increased. However, in study performed by Jahangiri et al.[3], described 7 patients who underwent placement of BDG without the use of either CPB or any form of decompressing shunt. They believe that no temporary shunt is needed if the cerebral perfusion pressure, is kept at 30 mm Hg or above. In Talwar et al[5], a hundred patients undergoing BDG were randomized into two groups: Off-CPB or on-CPB groups, All patients underwent near-infrared spectrophotometry (NIRS) and bispectral index (BIS) monitoring and pre- and postoperative serum 100 beta protein measurements (Sβ100) (In the developing CNS it acts as a neurotrophic factor and neuronal survival protein. In adults it is usually elevated due to nervous system damage, which makes it a potential clinical marker) and neuro-cognitive evaluation. There was a significant rise in superior vena cava (SVC) pressure on SVC clamping in the off-CPB group (23.12 ± 6.84 vs 2.98 ± 2.22 mm Hg) on-CPB group ($p < 0.001$). There was a significant fall in NIRS and BIS values from baseline in the off-CPB group during the anastomosis but there was no statistically significant change in serum Sβ100from pre-clamp to post-clamp in either group. In a study by Daubeney et al.[6], vulnerable periods with reduction in rSO2 during cardiac surgery were identified by observing the regional cerebral oxygenation in children using NIRS. There were reductions in rSO2 before bypass (during handling and dissection around the heart prior to and during caval cannulation). On the other hand in a study performed by ST Tan et al.[7], observed that periods during CPB when the rSO2 has been noted to decrease at the initiation of CPB, a decrease in rSO2 could be secondary to haemodilution. There may also be reduction in rSO2 during the rewarming after CPB due to an imbalance in oxygen supply and demand.

There was a significant correlation between low rSO2 and adverse neurological outcome; the five patients who experienced seizures had AUC more than the median value in both groups (> 500 min %). These data agreed with a study done by Austin et al[8], which studied 250 pediatric patients undergoing cardiac surgery and found that 41% of patients experienced prolonged periods of relative cerebral oxygen desaturation, defined as more than 20% decrease less than pre-bypass baseline. One-quarter of these patients with cerebral desaturation had postoperative adverse neurological events. Also, according to Slater et al. [9], stated that patients with cerebral rSO2 oxygen desaturation score of >500 min% had a significantly higher risk of post-op cognitive decline ($p=0.024$) and had a near three-fold increased risk of a prolonged hospital stay > 6 days ($p=0.007$).

It was clear that the presence of feedback from a specific indicator of an organ (cerebral oximetry) helped to raise the abilities of surgeons to detect and optimize silent but potentially adverse situations during surgical procedures. Neurological dysfunction is not always embolic, cerebral oxygen desaturation is associated with early postoperative neurological dysfunction in patients undergoing cardiac surgery.

Postoperative neurological outcome was satisfactory regarding both groups, there were no patients with major neurological insults, there were no patients with delayed recovery, all patients were evaluated to have 15/15 on modified Glasgow coma scale for infants and children and the difference in number of patients who experienced fits between both groups was statistically insignificant.

Preoperative data collected didn't show any statistical difference between both groups in preoperative risk factors so both groups were comparable. There was also insignificant difference between both groups in operative data. Postoperative evaluation was considering surgical outcome of the procedure, all patients had well-functioning Glenn shunt by echocardiography. Also there were insignificant difference between both groups regarding intensive care unit stay and hospital stay.

Abstract

In this study we evaluated the alcoholic extract of thyme "*Thymus vulgaris*", "*Salvia officinales*", "*Allium sativum*" and "thymol", "menthol" two pure compound effects on the viability of Echiniccousgranulsusprotoscolices in vitro. The different concentration of these four extracts were used (1, 1.5, 2.5, and 500 Mg/m), and (1, 10, 50 Mg/ml) for 3 different concentration each "thymol and menthol".Alcoholic extracts of both "thymol", *"Allium sativum"* and "salvia" in our results has an effecting on protoscolices viability, the best results showed in (2.500 Mg/ml) which is the highest concentration of Alcoholic extracts of both "thyme", *"Allium sativum*" and "salvia", by day 5.6 PT all protoscolices died. Salvia, thyme extracts in the (1.500, 1.000 Mg/ml) concentration. Concentration of 500 Mg/ml of these extracts showed significant effects of protoscolices activity on the 7th day. The loss of viability of protoscolices completely occurred with 500 Mg/ml concentration of these extracts at day 7th and day 8, day 3 post-treatment. "Menthol" and "thymol" menthol potent effects with 50 Mg/ml concentration at day 3 and 6 PT.

Keywords: *In vitro, hydatid cysts, protoscolices.*

Introduction

Adult of larval stages of cestodes belonging to the genus *Echinococcus* (family Taeniidae) which caused a near-cosmopolitan zoonosis (Echinococcosis). *"Echinoccousgranulosus*" and *"Echinoccousmultilocularis"* are the two major of public health and medical importance which cause cystic echinococcosis and alveolar echinococcosis.[1,2] Hydatidosis incidence has increased in various regions of the world which indicate by unfortunately numerous reports, there are two to three million human causes of hydatidosis in the world.[3] The most common mode of transmission in humans is the ingestion of *Echinococcus* eggs in feces of definitive host.[4] Echinococcosis is distributed throughout most of sheep in it, endemic in Asia, South and central North America, North Africa, Canada and Med iterance region. Hydatid cysts are more prevalent in rural areas, where there are close contact between dogs and people and different domestic animals which are play as intermediate hosts in many countries.[5] Significant advances have been made in chemotherapy of the metacestode stage of *Echinococcus*since the mid of 1970.[6] "Albendazolesulfoxide" injection demonstrated by Degere*t al.,* 2000 as a scolicidal agent in the precutaneous treatment of cystic echinococcosis, which seems to be effective in sheep[7] Synthetic anthelmintics used for treatment and control of parasitic disease, including helminthes and the appearance of its resistance stimulated the research for alternatives such as medical plants.(8) "Menthe", "Salvia" and "Thyme" are very popular medicinal plants in the Middle East with many folkloristic uses as well as all over the world. "Salvia" species used in traditional medicine for the relief of pain, *"S. officinalis* " is considered to have highest amount of essential oil compared with other in genus *"Saliva".*(9) "Thymus vulgaris" (thyme) because of his biological activity which related to their phenol compounds content such as "thymol" and caracole which represent between 40-50% of oils.(10) *"Allium sativum*" because of his biological activity which related to their Allicin substance that works on inhibiting metabolism

or effect the growth of the parasite (*Trypanosoma spp*., *Entamoebahistolytica* and *Giardia lambilia*. The aim of this study to determine the in vitro effect of *"T. vulgaris* "and *"Salvia"* and *"Allium sativum"* and "Menthol" "Albendazole" against *"E. granulosus"*protoscolices viability in comparison with control groups.

Materials and Method

"Echinococcusgranulosus" cysts were collected of human hydatid cysts following surgical removal in Educational Baghdad hospital.Cysts were washed several times in sterile PBS, PH 7.2 their surface sterilized by 70% ethyl alcohol, and its fertility determined by the presence of free protoscolices in cyst fluid by examination in wet amount drop by microscope.

To precipitate protoscolices form cyst fluid by evacuated them into 15 ml falcon tubes without centrifugation, for an hour to obtain hydatid sand at room temperature.

In a sterile preservation solution made of a mixture of Kerbs-Ringer solution (KRS)and hydatid cyst fluid the protoscolices was maintained for all experiments, and this solution does not contain any antibiotic or antifungal drugs.[12,13]

Results and Discusion

Hydatid cysts protoscolices viability were determined by the presence of protoscolices in the cystic fluid by wet mount drop, the viability of protoscolices tested prior to the experiment during 0.1 % aqueous eosin stain.

The viability of protoscolices treated with alcoholic extracts of *"Allium sativum*","*Saliva*", "thyme". Then all protoscolices treated with "menthol", "thymol" and "Albendazole".A comparison between all experimental results is summarized in table (1), fig (1)In recent years plant extracts uses against *E.granulosus*protoscolices received critical attention . Some certain plant species belonging to several families extracts my effect on the viability of the hydatid cyst protoscolices with or secondary hydatid cyst survival. [14]In our study we used the stain eosin o.1 % aqueous to assess the hydatid cyst viability andDrugs effect in vitro in hydatid cyst protoscolices . Colorless showed viable protoscolicesand other dead were absorbed to be in red color of o.1 % aqueous eosin. In this study the results agreement to the Ex in vitro studies [13,15] which recorded that best preservative medium for protoscolices was Krebs-Ringer solution with hydatid cystic fluid 4:1.This due to nutritional factors and a number of minerals (glucose, magnesium, chloride, potassium, chloride, sodium chloride, sodium phosphate dibasic and sodium phosphate monobasic) has been in Krebs-Ringer solution that gives the availability of hydatid cyst protoscolices to keep them alive for a long period of time for minimum requirement .[16]Alcoholic extracts of both "thyme", *"Allium sativum"* and "salvia" in our results has an effecting on Protoscolices viability, the best results showed in (2.500 Mg/ml) which is the highest concentration of Alcoholic extracts of both "thyme", *"Allium sativum*" and "salvia", by day 5.6 PT all protoscolices died. Salvia, thyme extracts in the (1.500, 1.000 Mg/ml) concentration causing death of protoscolices with longer period than the highest concentration. The dose of Medicinal plant extracts depend on their protoscolicidal effects on the breaking down the biological activities of hydatid cyst protoscolices by interference their metabolism.

Medicinal plant extracts maybe have specifically target sites, for example inhibitors of DNA synthesis, lick B-lactam antibiotics, inhibitors of protein, or within cytoplasm components, Allicine [11, 17, 18].

At days between 5 and 6 PT, with *"Allium sativum"* at concentration of "1.5 Mg/ml" and "1 Mg/ml" all protoscolices treated with them died, and at 4 day PT protoscolices treated with "menthol" at the same concentration.

Of both "thymol" and "menthol" "50 Mg/ml" treatment protoscolices died at days 5 and 3 PT. Successively, means menthol at 50 Mg/ml had the best effect followed by thymol at the same concentration on the viability of proscolices. our results agree with the report of Elissondo*et al*;.[19] High scolicidal activity of Methanolic extract of *"Allium sativum*" in vitro used as a scolicidal agent of the hydatid cyst surgical treatment.[20,21]

"Thymol" is one of the major components of essential oils of thyme which is defines as anti-microbial agent, and tested as a scolicidal agent an excellent effect in some studies and shows[19] Patients with hydatid disease treatment have an idea which had completely eliminated the parasite with prevention recurrence of the disease with minimal mortality and morbidity. Hydatosis available therapeutic modalities consist of, surgery, and percutaneous systemic chemotherapy treatment. [22]

Conclusion

Medicinal plant extracts of "*Allium sativum*", "thymol", "*salvia*" results in our study to pure compounds are potent scolicidal agents at different concentration. The dose-dependent efficacy of these plant extracts and pure compounds appeared to be more effective than that of "Albendazole" which did not induce its scolicidal effect before day 10 PT.

Abstract

Dialysis-related amyloidosis (DRA) is one of important complications occurring in hemodialysis patients and often presentsing as carpal tunnel syndrome (CTS), chronic arthropathy,subchondral cysts and pathological fracture tendency.In hemodialysis patients, there is increasing levels of beta-2-microglobulin (β-2m) in the plasma which is an important factor in DRA pathogenesis.

DRA commonly presents with CTS which is diagnosed clinically and verified by nerve conduction examination.Also(DRA) is main inducer of arthropathies in chronic HD patients due to β-2M accumulation forming amyloid fibrils which are deposited mainly on articular structures predominantly on articular cartilage in the early stage of DRA.

Cartilage biomarkers whether collagenous or non -collagenous are corresponding to cartilage destruction, degradation and turnover so their assessment is valuable in osteoarticular complications in HD patients.

The aim of this study is to access cartilage biomarkers, *β-2m* and PTX3 level changes in patients with DRA, their correlation to each other and to the clinical condition with evaluation of their value in diagnosis of DRA.

Keywords: *DRA, CTS, beta-2-microglobulin, Cartilage biomarkers.*

Introduction

Dialysis-related amyloidosis (DRA) is one of important complications occurring in hemodialysis patients and often presents as carpal tunnel syndrome (CTS), chronic arthropathy, presence of subchondral cysts and pathological fracture tendency[1]. High plasma beta-2-microglobulin (β-2m*)* level is an important factor for DRA pathogenesis.

DRA commonly presents as manifestations of CTS caused by median nerve entrapment from complexes of amyloid, its main component is β-2 microglobulin. Many authors reported it to be the most common mononeuropathy in end-stage renal disease (ESRD) patients[2,3] and considered increased beta-2-microglobulin *(β-2m)* and long duration of hemodialysis (HD) to be their most important causative factors. CTS is Diagnosed clinically and verified by nerve conduction examination.[4]

Osteoarticular complications are common among chronic hemodialysis (HD) patients[3] and their risk of development/progression is increased[5]. Today, DRA is commonly accepted as main inducer of arthropathies in chronic HD patients.

Pathophysiologically, the amyloid comprises β2m,a subunit of the major histocompatibility complex class I molecule and normally eliminated from the kidney circulation. It accumulates because of damaged kidney or inefficient removal from the circulation by HD therapy,fluxes into the synovial fluid[6] and form β2-m amyloid fibrils. Because of their affinity to glucosaminoglycans and collagens[7]. β2microglobulin fibrils are deposited in articular structures, especially in cartilaginous tissues causing cartilage destruction[8].

To address both, collagenous and non-collagenous matrix components,serum levels of type II collagen cleavage product (C2C) and procollagen II c-propeptide (CPII),aggrecan chondroitin sulfate 846 epitope (CS-846)[(9)] and cartilage oligomeric matrix protein (COMP)[10] were measured. In case of C2C and CPII the results are presented as the ratio of C2C/CPII, whose increase correlates with cartilage destruction[11,12]

In addition, the plasma levels of pentraxin (PTX)-3 found in HD patients were associated with inflammatory markers, comorbidity score, CVD and mortality with a prognostic power of similar magnitude as IL-6[8] and other inflammatory cytokines.

This work aims to assess cartilage biomarkers, β2m and PTX3 level changes in patients with DRA, their correlation to each other and to the clinical condition with evaluation of their value in diagnosis of DRA. Regarding that β2m is a marker of amyloid deposition and cartilage degradation in the early stage of DRA.

Patients and Method

This study included 75 subjects divided into three groups. 1) The Dialysis group included 37 patients; 22 males and 15 females on regular HD were recruited from the nephrology department (TBRI) with manifestations of dialysis related amyloidosis (DRA) as carpal tunnel syndrome (CTS), arthropathy, or both. All patients have HD sessions three times per week using low flux dialysis membranes. 2) The 2nd group included 21 patients (13 females and 8 males) with manifestations of CTS and/ or or arthropathy and were not on HD. Patients with a history and diagnosis of joint diseases were excluded from the study. 3) The third group included 17 normal subjects (10 females and 7 males).

All study subjects went into full history taking and clinical examination. Clinical grading of DRA was assessed through Function Status scale 4 [FSS] and Symptom Severity Scale [SSS] for CTS with measuring of pain intensity using a 100-mm pain visual analogue scale and Through [WOMAC Osteoarthritis Index], [Lequesnce Osteoarthritis Index] and visual analog scale [VAS] to provide information concerning joint pain 11.

Electrophysiological Diagnosis of median nerve entrapment at the level of the wrist (CTS) was confirmed by Nerve conduction studies (NCS) according to the American Association of Neuromuscular and Electrodiagnostic Medicine (AANEM)[6] by performing median nerve motor and sensory conduction studies to all cases as well as needle electromyography of the abductor Pollicis brevis muscle to selected cases for evaluation of CTS severity by using Deymed TRU-TRACE EMG NCV 4 Channel System machine (AU7-12060002) at the EMG unit of the Medical Center of Scientific Excellence of NRC.

Plain X_ Rays were done for all HD patients for detection of osteoarticular changes of DRA.

The sample size calculation was based on previous publications in this field which yielded a sample size of less than 15 for a ~100% difference with regard to serum levels of C2C, CPII and CS-846

Biochemical Assessment: Blood samples were obtained from each subject and serum was collected to be immediately frozen and stored at -25°C. The sample were thawed once to aliquot them and then refrozen, then thawed again to assay them. The ELISA biomarker assays (C2C, COMP, CP II, CS 846) were obtained from IBEX (Montreal, Canada). The intra-assay reproducibility of measurements of concentrations of C2C, CPII, COMP and CS846 was 9.7%, 6.4%, 10% and 11.5% respectively. Human Aggrecan neopepitope CS846 test was conducted using GSCIENCE (Glory Science Co., Ltd) ELIZA technique. Human Pentraxin 3 (PTX3), type II Collagec degradation (C2C) and Synthesis (CPII), Cartilage oligomeric matrix protein (COMP) tests were conducted using Sino Gene Clon Biotech Co., Ltd Eliza technique. Human β-2 microglobulin test was conducted using ORGENTEC Diagnostika GmbH Eliza technique.

Statistical Method: Statistical analysis was done using IBM© SPSS© Statistics version 22 (IBM© Corp., Armonk, NY, USA).Numerical data were expressed median and range.For quantitative data, comparison between two groups was done using independent sample t-test or Mann-Whitney test. Spearman-rho method was used to test correlation between numerical variables. A p-value < 0.05 was considered significant.

Results

In this study, we found by assessment of cartilage biomarkers in all groups no significant difference between all groups except in C2C level and B2-microglobulin level with (P value <0.001) where B2-m level is higher in group of dialysis patients than the other two groups, while C2C level is higher in both osteoarthritis group {with or without HD} than normal control group with no significant difference between each of the two osteoarthritis groups.

B2-microglobulin level, was significantly higher in hemodialysis group than the other 2 groups with significant correlation to C2C, CS846, COMP and increased significantly **[P value <0.001]** with increasing duration of dialysis. **Fig [1].** B2-microglobulin level also significantly correlated to C2C/CPII ratio.

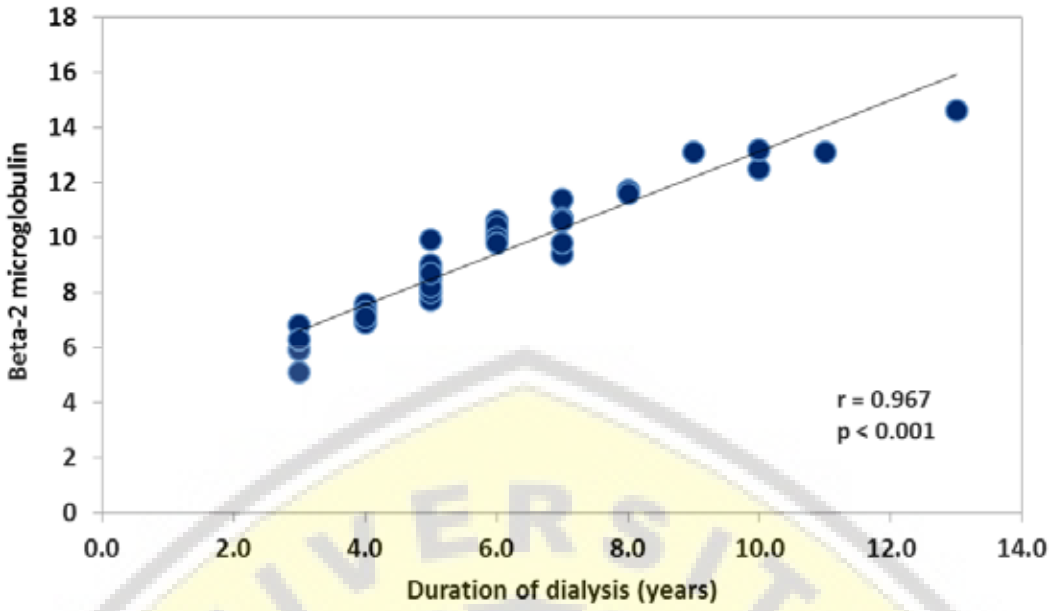

Fig [1]: Relation of B2-microglobulin level to duration of dialysis (years)

By following C2C/CPII Ratio, which is valuable measurement to express cartilage degradation, we found elevation in patients group whether on dialysis or not.

More important there was significant elevation in this ratio in hemodialysis patients after 5 years of dialysis with appearance of radiographing findings of DRA {juxta-articular soft tissue swellings, subchondral cystic lesions, mild periarticular osteoporosis} suggesting using this ratio as marker of occurrence of DRA

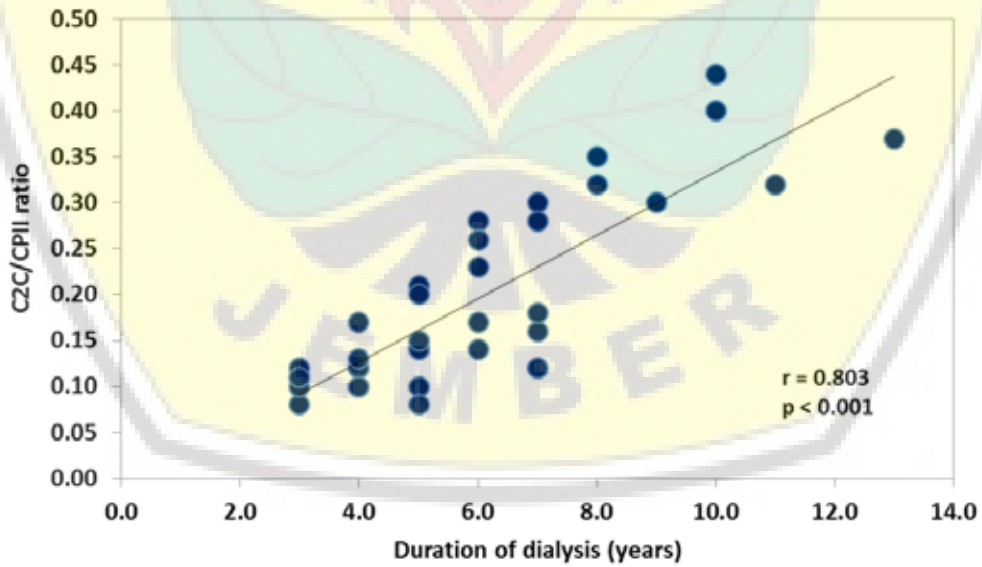

Fig [2]: Relation of C2C/CPII ratio to duration of dialysis (years)

	3-5 years on dialysis	>5 years on dialysis	P value
C2C	10.4 (3.1-14.7)	15.6(3.7-29.1)	<0.001
C2C/CPII ratio	0.08 (0.02-0.33)	0.15 (0.02- 2.5)	<0.001

Table [3]: Severity of Median nerve entrapment among hemodialysis patients detected by nerve conduction studies

	Mild	Moderate	Severe
No of patients	32.4%	27.2%	37.8%

Discussion

Dialysis-related amyloidosis is a major complication of long-term dialysis therapy due to deposition of amyloid fibrils,formed of β2 microglobulins (β2-m), in the osteoarticular structures and viscera,leading to a variety of pathological conditions affecting patient's quality of life[9].

Arthritis and carpal tunnel syndrome are the most prevalent musculoskeletal manifestations among hemodialysis patients with highly significantly affected physical function and disability[13]. In our study there was no significant correlation between clinical scales of osreoarthritis (WOMAC and Lequesence) and those of carpal tunnel(FSS and SSS) with serum biomarkers of the patients group.Some authors described a destructive arthritis which has not been attributed to amyloid deposition[14], while others reported a triad of shoulder periarthritis, carpal tunnel syndrome (CTS), and flexor tenosynovitis of the hands which was referred to β2-microglobulin amyloid deposition[15]. Busch et al.[16] also detected that CTS is a highly common manifestation of dialysis-related amyloidosis and that serum B2-microglobulin is one of its significant predictors. According to Nerve Conduction Studies, 37.8% of our hemodialysis patients had severe CTS requiring surgical release.

This study assessed serum B2-micriglobulin and cartilage biomarkers and their relation to DRA manifestations and to each other, we found high serum B2 microglobulin level among hemodialysis patients which is a specific predictive marker of DRA. Also we found by assessment of cartilage biomarkers that there is no significant difference between hemodialysis patients with manifestations of DRA in form of (osteoarthritis, carpal tunnel or both) and patients with manifestations of CTS and/or arthropathy not on HD except in C2C level and B2-microglobulin level, where B2 microglobulin level is higher in group of dialysis patients (B2-microglobulin initially deposits in articular cartilage initiating its destruction), while C2C level is higher in both osteoarthritis group {with or without HD} than normal control with no significant difference between each of the two osteoarthritis groups. A measurable increase in type II collagen denaturation is observed in early OA with a net loss of this molecule. This is associated with increased cleavage of collagen by collagenases.Conrozier et al foundC2C significantly lower in MSOA {multiple sites OA} than in OHOA {only hip OA}[17].

By studying correlation of cartilage biomarkers (C2C, CPII, Cs864 and COMP) as well as b2-Microglobulin, PTX3 with each other and with duration of dialysis, we found no significant correlation except relation between duration of dialysis and {B2-microgobulin, C2C and C2C/CPII Ratio} which was significant. As regarding B2-microglobulin level, it was significantly higher in hemodialysis patients than the non-HD patients and normal subjects. Asim et al found the β2-m levels were significantly elevated compared to control subjects [18].

High level of β2-m in this study was due to use of low-flux type of dialyzer in HD for our patients because to inability of low-flux dialyzers to clear these molecules with molecular weight of 12000 Da, conventional, this resulting to their accumulation in the body. Martin, et al.[19] also found that the cumulative pre-dialysis serum β2-m level was significantly lower with use of high-flux dialyzers than with use of low-flux dialyzers. The main reasons for using low-flux dialyzers in our patients are financial conditions.

By studying correlation between B2-microglobulin and cartilage biomarkers, there was significant correlation to C2C, CS846, COMP as well asB2-microglobulin level also significantly correlated to C2C/CPII ratio.

B2-microglobulin was found in this study increasing significantly with increasing duration of dialysis. As said by Schiffl et al. [20]. For the development of clinical effects of β2m, more than five to seven years are required.

Also Cs846 was found in this study, significantly correlated to other cartilage biomarkers including (CPII, C2C and COMP) as well as to B2-microglobulin and PTX3. These results are different from those of Ma et

al.[21] that showed no increase in CS-846 or COMP levels and hypothesize that after β2m-induced enzymatic release the majority of those molecules, or at least the sGAGs, were incorporated into the β2m deposits, as sGAGs enhance β2m amyloid formation and stabilize the fibrils [21].

By following C2C/CPII Ratio in our study which is a valuable measurement to express cartilage degradation, we found elevation in patients group whether on dialysis or not.

More important that there was significant elevation in this ratio in hemodialysis patients after 5 years of dialysis with appearance of radiographing findings of DRA {juxta-articular soft tissue swellings, subchondral cystic lesions, mild periarticular osteoporosis} suggesting using this ratio as marker of occurrence of DRA.

While Sunk, et al. [22] mentioned that patients on chronic HD for less than 5 years (1–2 years and 3–5 years HD groups) have significant increase in type II collagen degradation, as reflected by an elevated C2C/CPII ratio. As well as they observed a normalization of the C2C/CPII ratio after 5 years of HD. These results are different from ours as elevation of C2C/CPII was more after 5 years of dialysis as this is related to more cartilage distraction with longer dialysis therapy.

As many studies found significant elevation of B2-microglobulin level in patients on HD and increasing with duration of dialysis with significant correlation to occurring of DRA, they suggest using B2 microglobulin as a marker for DRA[22]. Also by accessing C2C/CPII ratio in our study and its significant correlation to duration of dialysis, radiographing findings of DRA and B2microglobulin level, this suggests using this ratio as a marker of DRA.

Prevalence of Klebsiellapneumoniae in Renal Failure Patients Using Genes Specific Primers

Abdalnabi J. Abid[1], Senan A. Almashta[1], Rana J. Ismail[1]

[1]*Department of Biology, College of Science for Women, University of Babylon, Iraq*

Abstract

Renal injuries were a big public problem all over the world that led to health complications and mortality. The current study was done to identify the bacteria isolated from patients with renal failure undergoing hemodialysis. The study included one hundred and two blood samples [sixty one male samples (59.8%) and forty one female samples (40.1%)], one hundred and fifty urine samples for patients undergoing hemodialysis in Marjan Teaching Hospital from November 2013 to June 2014. Sample were identified on plates. In addition to that, PCRs were applied using specific primers for detection of bacteria. Bacteriological investigations revealed positive cultures were 89.3%. The total number of isolates was 150. Gram negative bacteria were predominant and represented 84.3 %. While gram positive group were 15.67%. The most causative bacteria are *Escherichiae coli* [38.8%], followed by *Klebsiellapneumoniae* [34.32%], *Enterobacterspp* [6.71%] and *Pseudomonas aerogenosa* [4.47%] which belong to Gram negative bacteria. Whereas gram positive bacteria represent *Staphylococcus aureus* [13.43%] and *Staphylococcus epidermidis* [2.24%]. PCR assay were performed to identify the presence of some genes of *Klebsiellapneumoniae* isolates, and some of virulence, included [*cps, phoE*], the study revealed that *cps* gene found in 11 isolates out of 28 [39.28%].

Keywords: *K.pneumonia, cps, phoE, PCR, dialysis.*

Introduction

Renal failure is the inability of the kidneys to eliminate the metabolic end-products, and loss of the control to regulate the electrolytes, fluids and pH balance [1]. Some of the reasons of the renal failure may be local or systemic diseases or defects. This disease can be either acute or chronic. The acute type of renal failure can be cured if not left untreated. In contrast, chronic type means the permanant damage of the kidneys, and it may take years to develop[2]. Studies found the most common causative organism is *Escherichia coli* of kidney failure, but *Pseudomonas aeruginosa, Staphylococcus aureus* and *Staphylococcusepidermidis*may also cause this infection. Other gram-negative rods including *Klebsiellapneumoniae* and *Enterobacter spp*. are also cause Kidney failure [3]. The infection by these organisms can be due to virulence factors that present in these organisms such as pili, capsule and toxins; or caused as a result that some of the organisms considered as opportunistic pathogens [4]. Molecular study showed that the *cps* gene is found in *Klebsiellapneumonia*e and is considered as the major determinant for *K. pneumoniae* infections that could protect the bacteria from phagocytosis and killing by serum factors [5]. The *cps* gene also helps the bacteria to colonize the tissues and in biofilm formation[6]. The current study aimed to isolate and identify the bacteria correlated with renal failure, then used a molecular assay for the diagnosis of the predominant bacteria

Materials and Method

Collection of Samples: The patients were advised to clean the urethral area and allow the first drops of urine

to pass, then collect the samples of urine in a sterilized screw-cap container with 10 ml volume [7].

Isolation and identification of Bacteria: Standardized loop [2 mm in diameter] was used for transferring loop full of urine sample and streaking on nutrient agar, blood agar and MacConkey agar medium, incubated at 37˚C for 24-48 h.[8]. A single colony was taken from each primary positive culture and its identification depended on the morphology properties [Colony size, shape, color, type of pigments, translucency, edge, elevation, and texture]. After staining the bacteria by gram stains, specific biochemical tests were done to reach the final identification [9]. Various biochemical reagents and tests were used for the identification of bacteria [10]. For molecular assay, DNA was extracted from pure bacterial isolates by using a Geneaid DNA purification kit and in accordance with the manufacturer's protocols. The lyophilized oligonucleotide upstream and downstream primers were prepared according to the manufacturing company [Bioneer] and kept at -20 ºC.Polymerase Chain Reaction (PCR) were performed in a total volume of 20 µl containing 3µl of both the forward and reverse primers, 5 µl master mix, 4 µl free water nuclease and 5 µl of the extracted DNA [as DNA template], then DNA amplification was carried out with the thermal cycler.

Thermal Cycling Conditions: The reaction was performed in a PCR thermal cycler apparatus, and after several trials, and according to the manufacture's troubleshooting guide the program was adopted as table 1.

Agarose Gel Electrophoresis: The method performed in this study was according to Bartlett and Stirling, 1998. The amplified PCR products were detected by agarose gel electrophoresis was visualized by staining with ethidium bromide. The electrophoresis DNA bands were detected by using gel documentation system. The positive results were distinguished when the DNA band size of the sample equals the target product size Bartlett and Stirling,1998. Finally, the gel was photographed using E-graph gel documentation system.

Results and Discusion

The present study included the collection of 150 urine samples collected from hemodialysis patients, from laboratories of the artificial kidney unit in Merjan Teaching Hospital. Morphological and biochemical characterization indicated that 134 [89.3%] of the samples had bacterial growth and 16 [10.6%] of them had no growth, as shown in table [2] below. The results of the urine cultures and biochemical tests for isolated bacteria from hemodialysis patients revealed that *Escherichia coli* is the most common bacteria 52 [38.8 %], followed by *Klebsiellapneumoniae* 46 [34.32%], *Staphylococcus aureus* 18[13.43%], *Enterobacter spp.* 9 [6.71%], *Pseudomonas aeruginosa* 6 [4.47%] and *Staphylococcus epidermidis*3 [2.23%] as shown in figure (1).

Diagnosis of Klebsiellapneumoniaeisolates by PCR: A total of 150 urine samples were collected from hemodialysis Patients. Only 46 isolates [34.32%] of *K.pneumoniae* were identified according to the morphological characterization, biochemical tests, and the two genes selected for molecular diagnosis of *K. pneumoniae*.

Detection of the cps gene: Capsular polysaccharide gene [cps] was investigated through a specific pair of primers for 28 isolates that identified by biochemical test. It was found that 11 [39.28%] isolates of *Klebsiellapneumoniae* gave positive results for this gene whereas 17 [60.71%] isolates gave negative results. These results were shown in Figure (2).

Detection of phoE gene: Phosphoporin protein E gene [*phoE*] was investigated through a specific pair of primers for 28 isolates that identified by the biochemical tests. It was found that 8[28.57%] isolates of *Klebsiellapneumoniae* gave positive results for this gene, whereas 20 [71.42%] isolates gave negative results . These results were shown in Figure (3).

The present study included the collection of 150 Urine samples, Morphological and biochemical characterization indicated that 134 [89.3%] of samples had positive bacterial cultures and 16 [10.6%] of them had negative culture. Patients with kidney failure are more prone to developing urinary tract infections, the mere act of passing urine tends to flush out the urinary tract of infectious bacteria to prevent causing urinary tract infection [12]. The bacteria live in the intestine can infect the urinary tract which may be explained by a greater incidence of urinary obstructions which in turn lead to infections [13].These results were agreed with another result obtained by [14], which had reported that 78.4% of patients with UTI had positive culture and those with negative culture may be associated with Mycoplasmal or Chlamydial infections. Approximately, 20% of women attending to sexually transmitted diseases clinic have *Mycoplasma* in their urinary tract[15]

The results of urine culture and biochemical tests for isolated bacteria from hemodialysis patients revealed that *Escherichia coli* is the most common bacteria with 52 isolates [38.8%], followed by *Klebsiellapneumoniae* 46 [34.32%], *Staphylococcus aureus* 18 [13.43%], *Enterobacter spp.*9 [6.71%], *Pseudomonas aeruginosa* 6 [4.47%] and *Staphylococcus epidermidis*3 [2.23%]. These results were agreed with another result obtained by[16], when he studied genitourinary tract infections among women in Mosul and showed that [33.6%] of UTI in women were caused by *Escherichia coli*. Additionally[17] showed that 47% of UTI were caused by *Escherichia coli*,Generally, *Escherichia coli* is the most common bacteria because it has some virulence factors which helps in pathogenesis. Components such as pili, which are responsible for the adherence in the urinary tract epithelium, aids the bacteria to ascend to the kidneys[18]. However, it appeared that *K pneumoniae* is the second causative agent in this study because it is isolated from [34.32%] of all isolates. So, it was different from [16], who showed that only [10.8%] of UTI among women in Mosul were caused by *K. pneumonia*e. On the other hand, [19] who showed that 11% of UTI were caused by *K. pneumonia*e. The difference between the recent study[19] and[16] may reflect the difference in population behavior or personal hygiene because *K. pneumonia*e is present in feces of about 5% of normal individuals [15], so bad hygiene may lead to the UTI.In addition to *E. coli* and *K. pneumonia*e, *Staphylococcus aureus* was important causative agent that found in this study, because itrepresented [13.43%] of all isolates.So, these results were different from the results obtained byepidemiological studies which reported that 40-60% of hemodialysis patients are carriers of *Staphylococcus* as normal flora [20,21]. One of the most cause of UTI in hospitalized patients is *Pseudomonas aeruginosa* due to its ability to resist different types of antibiotics and other chemicals which used in sterilization processes in hospitals[22]. A total of 150 urine samples were collected from hemodialysis Patients. Only 46 isolates [34.32%] of *K.pneumoniae* were identified according to the morphological characterization, biochemical tests and the two genes that were selected for the molecular diagnosis of *K. pneumoniae*. Capsular polysaccharide gene [*cps*] was investigated through specific primer for 28 isolates that identified by the biochemical tests. It was found that 11 [39.28%] isolates of *K. pneumoniae* gave positive results for this gene, whereas 17 [60.71%] isolates gave negative results. The presence of the *cps* reduces the binding of antimicrobial peptides to bacterial surface and this will promote the bacterial resistance to antibiotics. The genomic organization of chromosomal *cps* region is responsible for *cps* biosynthesis in *K. pneumoniae*, indicates thatthe majority of clinical isolates of *K. pneumoniae* express pronounced capsule polysaccharide that is essential to virulence of *Klebsiella*[23]. In this study, only 11 [39.28%] bacterial isolates gave positive results for this gene. The variation in isolation rate may be due to a technical error or to variation in strains of bacteria. Also[24] found that *cps* of *K. pneumoniae* is mostly responsible for serotype of *K. pneumoniae* capsular polysaccharide. Additionally[25] found that *cps* of *K. pneumoniae* is responsible for serotype *K. pneumoniae* capsular polysaccharide, *cps* is considered as the major determinant for *K. pneumoniae* infections that could protect the bacteria from phagocytosis and killing by serum factors[26]. The gene *cps* is also helping the bacteria to colonize the tissues and Biofilm formation[25]. Phosphoporin protein E gene [*phoE*] was investigated through specific primer for 28 isolates that identified by biochemical test. It was found that 8 [28.57%] isolates of *K. pneumoniae* give positive results for this gene, whereas 20 [71.42%] isolates give negative results. Because this gene is important for *Klebsiellapneumoniae*, crystallographic studies showed that *phoE* forms a 16-strand anti parallel barrel[27]. The PhoE unit consists of three fragments[28].

Table 1. The thermal cycler conditions of the primers used in the study

Table 2. Number and Percentages of positive and negative sample cultures.

Urine Culture	Number	Percentage
Culture positive	134	89.3%
Culture negative	16	10.6%
Total	150	100%

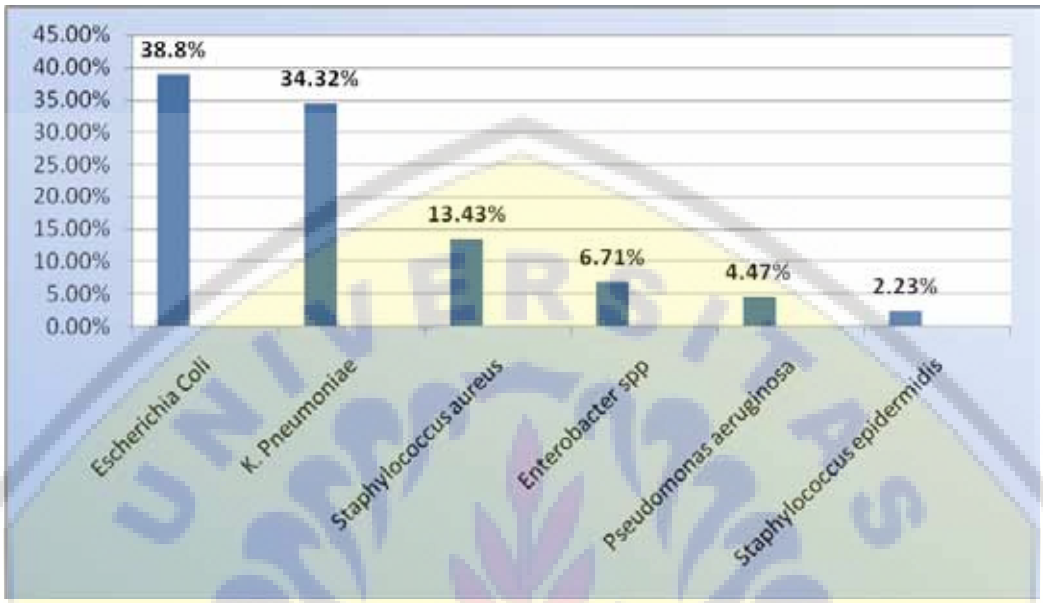

Figure 1. Incidence of bacterial isolates in renal failure patients.

Figure 2. Agarose gel electrophoresis of PCR products for the detection of Capsular polysaccharide [cps] gene in Klebsiellapneumoniae. Lanes 1-12 refer to isolates' number. L= DNA ladder.

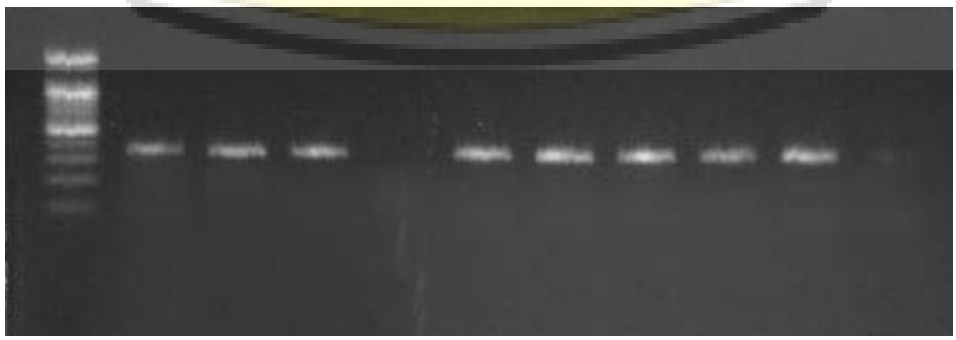

Figure 3. Electrophoresis image for the detection of the phosphoporin protein E[phoE] gene in Klebsiellapneumoniae. Lanes 1-10 refer to isolates' number. L= DNA ladder.

Conclusion

Various types of pathogenic bacteria were isolated from urine samples of hemodialysis patients. *K. pneumonia*e form one of the most isolated bacteria that identified with conventional and molecular investigations. Virulence genes included [*cps, phoE*] were investigated to identify the presence of *Klebsiellapneumoniae*, both genes gave a positive result with percentages [39.28%] and [28.57%], respectively .

Impact of Weight Loss on Ventilatory Functions in Obese Asthmatic Children

Fathia Mostafa Gelany[1], Kamal Elsayed Shoukry[2], Elham Elsayed Salem[2], Mohamad Shahat Badawy[3]

[1]MS., Department of Physical Therapy for Growth and Development Disorders in Children and its Surgery, Faculty of Physical Therapy, Cairo University, Egypt, [2]Prof., Department of Physical Therapy for Growth and Development Disorders in Children and its Surgery, Faculty of Physical Therapy, Cairo University, Egypt, [3]Prof., Department of Chest Diseases, Qena Faculty of Medicine, South Valley University, Egypt

Abstract

Background: The effect of weight loss by whole body vibration on ventilatory functions in obese asthmatic children. Materials and Method: Forty obese asthmatic children from both sexes aged from 8 to 12 years were participated and were assigned to 2 groups of equal number. Group A received balanced caloric diet and breathing exercises. Group B received the same program of group A in addition to whole body vibration. The treatment program was conducted 3 sessions/week for 3 successive months.

Anthropometric measures (weight, height, body mass index and waist circumference) and ventilatory functions measures (FVC, FEV1, FVC/FEV1%, PEFR) before and after 3 mon for both groups. Results: Significant improvement of all measuring variables including anthropometric and ventilatory functions parameters in both groups after treatment ($p<0.05$). However, no significant differences were found among control and study groups after treatment in all measured variables. Conclusion: The balanced caloric diet and breathing exercises were effective in decreasing Anthropometric measures and improving ventilatory functions in obese asthmatic children.

Keywords: *Asthma, obesity, ventilatory functions, whole body vibration*

Introduction

Asthma is chronic inflammatory disorder of the airways. Chronically inflamed airway is hyperresponsive become obstructed and air flow is limited[1].

Overweight and obesity are worldwide health crises in children .More than 33% of children have overweight or obese[2]. Overweight teens mainly would track to adult as overweight and led to health problems[3,4].

Obesity observed with medical and social morbidity which could be led to respiratory problems and bronchial hyperactivity[5].

Differences of asthma and obesity are provided by pervious investigations, where they found the risk for asthma increases with increase BMI[6-9]. Obesity is high risk for incident asthma and increase from being overweight to obese[10]. as obese asthmatic loses body weight, their asthma symptoms and lung functions improve[11].

Lung function measurements in children results with asthma include forced expiratory in FEV1, FVC, FEV1/FVC and PEFR. Related to lung volumes vary with age, sex, and height, FEV1 and FVC were noted as % predicted values based on nomograms of children healthy[12].

Researchers analyzed data from Childhood Asthma

Management to determine the effect of BMI on lung function, whose reported increase BMI with increase FEV1 and FVC % predicted and reduced FEV1/FVC of airway obstruction.

Diet programs may produce weight loss in 67% of people lost more than 10% body mass and maintain or continue to lose weight later. Average maintained weight loss of more than 3 kg or 3% of total body mass could be sustained for 5 years[13].

WBV is alternative exercise modality become increase in gyms and might address time constraints and compliance issues[14].

Vissers et al.[15]: found adding WBV to a hypocaloric diet led to decrease fat % post 3, 6 and 12 months of WBV training by (4.8 %), (7.0%) and (5.5 %) respectively.

This study was performed to determine if weight loss by WBV has an effect on ventilatory functions of obese asthmatic children.

Materials and Method

Study Design: This study was an experimental study conducted at Outpatient clinic, chest department at Faculty of Medicine South Valley University, Qena, Egypt from December 2015-to April 2018.

Subjects: Forty obese asthmatic children (of both sexes) aged from 8-12 years (mean age 10.9±1.355) participated in this study after their parents signed consent form for their children's participation. Children were included if they had: controlled asthma, mild to moderate asthma, BMI 85th ≤99th percentile **(http// www.cdc.gov/growthcharts)**[16].

And excluded if; they received medication other than treatment of asthma, severe or very severe asthma, other chest problems other than asthma or cardiac diseases.

Materials:

1. **Spirometer: Micro Lab Spirometer (VIASYS)** made in **France**, desk top Spirometer with printer and color touch screen was used to assess ventilatory function (FVC, FEV1, FVC/FEV1%, PEFR) were measured pre and post 3 months of treatment for children of both groups.
2. **Standard weight and height scale** to measure weight (kg) and height (cm). These parameters are essential to feed the spirometer and to calculate BMI of all children of both groups**.**
3. **Round tape measurement** to measure waist circumference (cm).
4. **BMI chart (Growth Curves)** for gender. **(http// www.cdc.gov/growthcharts)** [16].

BMI Mass Index-for-Age Percentiles: for Boys and for Girls 2 – 20 years for the selected age (8-12).

Procedures:

Evaluative procedures:

A-Evaluation of Anthropometric measures:

1. The body height (ht) measured to the nearest 0.1 cm by standard weight and height scale.
2. The body weight (wt) determined to the nearest 0.01 kg on a Standard weight and height scale.
3. Body mass index (BMI) was calculated as body weight (kg) divided by body height (m²).
4. Waist circumference (WC) was measured at the level of the umbilicus by round tape measurement to the nearest 0.1 cm.

For all measurements, children were asked to stand with feet close together. The child had to be relaxed. Each measurement was repeated twice **(WHO report[17]).**

5. **Evaluation of ventilatory function ((FVC, FEV1, FVC/FEV1%, PEFR)** according to**: Jones and Pierce[18]** :
   - Spirometery was used to measure the selected ventilatory function parameters including (FVC, FEV1, FVC/FEV1%, PEFR).
   - Actual and predicted values for each parameter were recorded.

II. Treatment procedures:

1. Whole Body Vibration for treatment (EVERE, made in china with different speed (S0, S1, S2,…S9) and different time (100s,300s,500s).

Children in group B received balanced caloric diet and breathing exercises given to group A in addition to WBV.

1. **Diet:** Based on the energy needs of healthy children are determined on the Basis of basal metabolism, rate of growth, and energy expenditure .Dietary energy must be sufficient ensure growth but not allow excess weight gain. Intake proportions of energy are 4 5%to 65% carbohydrates for 4 to 18year olds, 2 5% to 35% fat, and l0% to 30% protein **(IOM [19]).**
2. **Breathing exercises were applied to improve ventilation, promote relaxation and to correct inefficient or breathing pattern in the form of Diaphragmatic breathing and Pursed lip breathing.**
3. **Whole Body Vibration (WBV):** 3 phases were conducted
   (a) **Warming up**: warming up period were 10 minutes in form of stretching exercises
   (b) **Active period** on vibration machine
   (c) **Cooling down**: was performed after the active period, for bringing the heart rate to its pre exercise level in form of walking in place followed by breathing exercise.

Protocol of vibration: Modified from **Vissers et al. 15:**

The protocol was conducted for children of group B

*3 months program, 3 times/week, training session consisted of different exercises including muscles of the whole body

*Exercises: from standing, sitting, squatting

- Training protocol was designed with a gradual increase in speed (S0, S1, S2,…, S9)
- Time of exercise (100 – 300 – 500 sec).
- The graduated training protocol were as follow:
- First month the time was 100s exercise and rest time 30s and speed was S0, total duration of exercise was 10 min.
- Second month the time was 100s exercise and rest time 30s and speed was S0 and S1, total duration of exercise was 10 min.
- Third month the time was 100s exercise and rest time 30s and speed was S0, S1 and S2 total duration of exercise was 10 min.

Data Analysis: All statistics were calculated by

1. **Descriptive Statistic:** The mean and standard deviation for the anthropometric(weight, height, BMI and waist circumference) and ventilatory function parameters (FVC, FEV1, FVC/FEV1%, PEFR) were calculated for each variable pre the treatment and post 3 months of treatment for both groups (A and B).
2. **Inferential Statistic:** Mannwhiteny test – was used for each variable to compare the results pre and post 3 months of treatment for each group (A and B).

Results

Table 1 showed demographical and clinical results of both groups. Mean age of group A and group B were 11.0±1.2 and10.8±1.4 years respectively.

Group A: The data in table 2 revealed anthropometric and ventilatory function parameters pre and post treatment in group A: the results showed significant difference of all measured parameters except FVC/FEV1 non-significant difference.

Group B: The data in table 3 revealed anthropometric and ventilatory function parameters pre and post treatment in group B: it showed significant difference of all parameters except FVC/FEV1 non-significant difference.

Group A & B: The data in table 4 revealed anthropometric and ventilatory functio parameters post treatment in group A and B using: the results showed non-significant difference of all parameters

Discussion

Results of current study showed that there were statistically significant difference of the mean values before and after treatment of the group A in anthropometric (weight, BMI, WC) and ventilatory function measured parameters (FVC, FEV1, PEFR) except FVC/FEV1% showed no significant difference. This come in agreement with **Kopelman et al.**[20]: Increase excessive fat % effect on lungs activities and limits the free air[21]. Results of current study showed that there were statistically significant difference of the mean values before and after treatment of the group B in anthropometric (weight, BMI, WC) and ventilatory function measured parameters (FVC, FEV1, PEFR) except FVC/FEV1 showed no significant difference

In agreement with **Salome et al.**[22]: Obesity could potentially worsen asthma, as effects on pulmonary physiology and mechanics. Increasing weight could had profound implications on lung physiology and develop the restriction system from greater adiposity around the chest wall and abdomen. Reduced lung capacity and low expiratory reserve volume, from upward diaphragmatic displacement due to increase abdominal fat and could led to ventilation/perfusion mismatching, not the amount of fat but location of fat influences asthma perceptions **Lessard et al.**[23]. Weight loss interventions, both surgical and nutritional can improve respiratory health. Improve of BHR only with low or normal IgE levels, and different phenotypes may benefit from weight loss[24]. Spirometric variables, as forced expiratory volume in 1 s (FEV1) and forced vital capacity (FVC), tend to decreased with increased BMI[25]. On the other hand **Ross et al.**[26]: had not found any difference in pulmonary function among obese and non-obese. Various investigations reported that correlation between increase BMI and increase asthma severity[27].

The results of the current study agreed with **Roelants et al.**[28] who reported WBV training induces small increase in fat free mass had not reduced body weight, fat% or subcutaneous fat in untrained females and WBV reduction, fat accumulation and serum leptin without affecting muscle function. With agreement of the current study **Rubin et al.**[29] adipogenesis is inhibited in mice by brief, daily exposure to low-magnitude mechanical signals, delivered via WBV.

Conclusion

The diet and breathing exercise are effective in decreasing body weight and BMI and improving ventilatory functions in obese asthmatic children

Identification of Bacterial Species Associated with Dental Caries and Evaluated of Antimicrobial Activity of Aqueous and Alcoholic Extracts for Suaedaaegyptiaca and Citrus Sinensis Plants

Ghosoon Al-Kanaany

Department of biology, College of Science,University of Basrah, Iraq.

Abstract

Studies were carried out to identify 32 bacteria isolated from dental caries belong to the genera: *Escherichia*, *Pseudomonas*, *Citrobacter*, *Sphingobacterium*, *Staphylococcus*, *Leuconostoc*, *Acinetobacter*, *Ochrobactrum*, *Klebsiella*, *Enterococcus*, *Yersinia*, *Chromobacterium* and 18 isolates were unidentified by Vitek$_2$ compact system. Antibacterial activity of *Suaedaaegyptiaca* and *Citrussinensis* plants was investigated. Peels orange (*Citrussinensis)* were extracted with hot water, and then its antibacterial activity against Gram-positive and Gram-negative bacteriawas examined, the data demonstrate the effect was more against the bacteria S*phingobacteriumthalpophilu*m with inhibition zone of 30 mm at 500mg/ml concentration whereas aqueous extract of peels orange revealed no effect on the bacterial species (*Leuconostocmesenteroides*, *Ochrobactrum anthropic*, *Escherichia coli*). On the other hand methanol extracts of peels orange had effected on one species only (*Citrobacterfreundii*). The study also indicated that aqueous extract of *Suaedaaegyptiac*a plant do not effect on all bacterial species tested while methanol extract of *Suaedaaegyptiac*a revealed activity on the species (*Klebsiellapneumoniae, Pseudomonas oryzihabitans*, *Staphylococcus vitulinus)*.

Keywords: *Citrus, Suaeda, antimicrobial activity, Vitek 2 compact system.*

Introduction

Dental caries, also known as tooth decay, a chronic disease is unique among human and is one of the most common important global oral health problems in the world today[1,2]. Destruction of calcified tissue was caused by acids which are by product from the bacterial fermentation of dietary carbohydrates especially sucrose[1,3]. Dental caries occurs due to multiple factors such as interactions within the plaque community,diet,fluoride, hostphysiology, pH and nature of the tooth enamel, caries is also associated with poor cleaning of the mouth (1; 4). The term of medicinal plants include a various types of plants used in herbalism and some of these plants have a medicinal activities. These medicinal plants consider as a rich resources of ingredients which can be used in drug development and synthesis. some plants consider as important source of nutrition and as a result of that these plants recommended for their therapeutic values,other plants consider as important source for active ingredients which are used in aspirin and toothpaste [5].Plants as a source of medicinal compounds have continued to play a dominant role in the maintenance of human health since ancient times. According to the World Health Organization plant extracts or their active constituents are used as folk medicine in traditional therapies of 80% of the world drugs are of natural product origin [6] .Pharmaceutical companies have spent a lot of time and money in developing natural products extracted from

Corresponding Author:
Ghosoon Al-Kanaany
Department of biology, College of Science,University of Basrah, Iraq
e-mail: gh_fadhel@yahoo.com

plants to produce more cost effective remedies that are affordable to the population [7].Medicinal plants are a source for a wide variety of natural antioxidants and are used for the treatment of diseases during the world [8]. Some of these properties are antimicrobial [9], anti-diabetic [10], anti-cancer [11], immunomodulatory[13], anti-atherosclerosis [13], Recently, due to beneficial effects of antioxidants in the treatment and prevention of diseases, there has been a considerable interest in finding natural antioxidants from plant sources. In most of countries in Europe, herbal medicines are either fully licensed as medicines with efficacy proven by clinical trials. In Iran and in the United States, most herbal products are considered as dietary supplements and thus are not required to meet the standards for drugs[14].*Citrus* is the most economically important fruit crop in the world *Citrus* fruit is grown all over the world in more than 140 countries [15,16].*Citrus* fruits have been recognized as an important food and integrated as part of our daily diet, playing key roles in supplying energy and nutrients and in health promotion.Orange trees are widely cultivated in tropical and subtropical climates for its tasty juice and medicinal value. *Citrus senensis*peel has many medicinal properties and is widely used against various ailments, such as colic, cancer, diuretic, cormunative, immuno – enhancing, tonic to digestive system, stomachic, immune system and skin. It is also used to treat and prevent vitamin deficiencies, colds, flu, and scurvy and helping to fight viral and bacterial infections [17,18].

Suaedaaegyptiaca plant: This herb is widespread in Canary Islands, Europe, Mediterranean region, Asia, Australia, northeast coast of North America, Argentina. Many of which are adapted to live in saline soil and live in salt marches or arid saline soil [20].

The species distributed throughout Arabia in saline habitats especially on coasts and it is grow in rather different plant communities and even as weed in irrigated gardens and fields [21]. The present study aims at isolation, characterization of bacterial species are associated with dental caries and evaluates antimicrobial activity of peels *Citrus sinensis* and *Suaedaaegyptiaca* plants extraction.

Materials and Method

Collection of Samples: 60 samples were collected from patients (for both sexs females and males with different ages)suffering from dental caries from Al-Basrah general hospital by using sterile cotton swabs and dissolved into 2ml brain heart infusion broth media after then transported to the laboratory and incubated at 37°C for 48 hours.

Collection of Plants: *Suaedaaegyptiaca* plant samples were collected from garden college of scince university of Basrah and peels of *Citrus sinensis* collected from local markets in Basrah province. Aerial parts of this plant were cleaned with running water after then with sterile distilled water, and air dried at room temperature (25°C)for three days, then samples were grounded into powder by electrical sterilized mixer grinder. The powdered parts were kept in plastic bags at 4°C until use.

Identification of bacterial isolates: All the isolates were inoculated on nutrient, MacConkey and blood agar plates. The streaked plates were incubated at 37°C for 24 hours. Identification of isolates were done based on colony morphology later Gram stained (23). Identification with the Vitek-2 system was performed with ID-GN, ID-GP cards, according to the manufacturer's instructions.

Preparation of plants extracts: Water extract of plant was prepared by weighting 20g of plant powder in conical flask, and 400 ml of distilled water was added then mixed with hot plate and magnetic stirrer for six hours. The mixture was filtered through filter paper (Wattman No. 1) and the filtered extract was concentrated with rotary evaporator, then the aqueous extract left at room temperature to remove any exess water.

Methanolic extract of plant was prepared by weighting 20g of plant powder was mixed with 400ml of methanol by successive continuous hot percolation using Soxhlet extractor for 8 hours at 60ºC. The solution was evaporated to dryness in a rotary evaporator [24,25].

Antimicrobial activities assays: The antibacterial activities of the plants extracts were evaluated by agar well diffusion method [26]. Tested bacterial genera were grown in nutrient broth to match the turbidity of 0.5 McFarland standards to be inoculated on plate Muller-Hinton agar by sterile cotton swabs . After inoculation, plates were dried for 15-20 min, and the wells were punched using sterile cork borers. Once wells were formed, they were filled with 100 µl of each plant extract (water, methanol) that dissolved in dimethyl sulphoxide (DMSO), where each plant extract was prepared with different concentrations (100,200,300,400,500) mg/ml. Plates were incubated for 24 hours at 37°C to allow plants extracts to diffuse through the agar media to

form zones of inhibition. The diameters of the zone of inhibition for different plants extracts against different bacteria were measured in millimeter. An agar well (6 mm) showing no zone of inhibition was considered as no antimicrobial activity. All experiments were done in triplicate and the mean values were used [25].

Results and Discusion

Identification of bacterial isolates: Among 60 clinical samples were collected from patients suffering from dental caries from Al-Basrah general hospital in Basrah province,50 isolates characterized by using conventional method, whereas the isolates exhibited differential hemolysis pattern on blood agar and some of isolates ferment lactose when grown on MacConkey media.

The results showed some isolates were Gram positive and other isolates were Gram negative when stained with Gram stain. The identification results with $Vitek_2$ compact system were grouped in Table 1. Among 50 bacterial isolates,32 isolates identified to genera *(Escherichia*, *Pseudomonas*, *Citrobacter*, *Sphingobacterium*, *Staphylococcus*, *Leuconostoc*, *Acinetobacter*, *Ochrobactrum*, *Klebsiella*, *Enterococcus*, *Yersinia*, *Chromobacterium*),18 isolates were non identified. The results demonstrated that the bacteria isolates characterized at spec- ies level by $Vitek_2$ compact system was divided into four groups based upon thethe probability of accurate identification as follows:14 isolates with probability of accurate identify-cation (96-99%),9 isolates with (93 - 95%),6 isolates with good (89- 92%),3 isolates with (85 - 88%).

Antibacterial activity of aqueous and methanolic extracts of Suaedaaegyptiacaand Citrussinensis plants on some bacterial species: The present study showed the antimicrobial activity of peels oranges plant aqueous extract against some of bacterial isolates which obtained from dental caries for both Gram positive and Gram negative bacteria, whereas S*phingobacteriumthalpophilu*m had the highest microbial sensitivity (zone of inhibition 30 mm with concentration 500mg/ml of peels oranges aqueous extract) and this inhibitory effect increased with increasing aqueous extract concentration, Fig. 1. Aqueous extract of peels oranges revealed different inhibition zones against other bacterial isolates and this study demonstrated that this aqueous extract do not revealed any effect on the isolates (*Leuconostocmesenteroides*, *Ochrobactrum anthropic*, *Escherichia coli*). methanol extracts of peels oranges effected on one isolate only (*Citrobacterfreundii*) and do not effect on the other bacterial isolates as show in Table 2, Fig.2. The results showed that aqueous extract of *Suaedaaegyptiac*a plant do not effect on all bacterial isolates tested while methanol extract of *Suaedaaegyptiac*a revealed activity on the isolates (*Klebsiellapneumoniae, Pseudomonas oryzihabitans*, *Staphylococcusvitulinus)* with different inhibition zones whereas*Klebsiellapneum- oniae* had the highest inhibition zone 15mm in 500mg/ml concentration as show in Table 3, Fig.3.Oral diseases sources major health problems in the worldwide [27].In the recent study the bacterial isolates isolated from dental caries identified with $Vitek_2$ compact system after identified by conventional method because $Vitek_2$ compact system is an option which proven to reduce turn around times and improve the quality and reproducibility of microbiology results, the $Vitek_2$ system have several advantages that may be of clinical interest for routine testing of gram-negative and gram-positive isolated from the clinical samples: Rapid identification (during three hours), a high level of automation and taxonomically updated databases [28,29].From the generalized data is revealed that the greater zone of inhibition exhibited by hot aqueous extract of peel orange (*Citrussinensis*) against*Sphingobacterium*thalpophilum while hot methanolic extract of peel orange do not effect against all isolates exception *Citrobacterfreundii* this inhibition effect may be related to its active compounds that includes tannins, saponins, phenolic compounds, essential oils and flavonoids and others[34] this results do not agree with study of [18], who explained that the alcoholic extracts more effective against pathogens than the aqueous extractsof peels orange (*Citrussinensis*).Inhibition zone of all extracts against pathogens in this study increased with increase in concentration which is in agreement with previous studies[17].also results obtained showed the aqueous extract of *Suaedaaegyptiaca* do not effect on all bacterial isolates were tested this study does not similar to those obtained by [24] who reported antibacterial activity of aqueous extract of *S. aegyptiaca*was examined against four pathogenic bacteria: *Staphylococcus aureus, Escherichia coli, Salmonella typhi and Shigelladesynterial*. whilemethanolicextract of *Suaedaaegyptiac*a revealed activity on the isolates (*Klebsiellapneumoniae, Pseudomonas oryzihabitans*, *Staphylococcus vitulinus)*, this results agreement with study [24], who showed that ethanolic extract had inhibitory effect on *Staphylococcus aureus, Staphylococcus.*

*epidermidis*and *Klebseillapneumoniae*. Chemical analysis showed that *S. aegyptiaca* contains different active compounds: phenols, alkaloids and terpens .

Exercises Versus Acupuncture for Overweight Children

Mohammed Emad Eldin M. Esmail[1], Samia A. Abdel Rahman[2], Gehan Mosaad Abd El Maksoud[2]

[1]MSc in Physical Therapy, Faculty of Physical Therapy, Cairo University, Cairo, Egypt, [2]Professor, Physical Therapy for Pediatrics Department, Faculty of Physical Therapy, Cairo University, Cairo, Egypt

Abstract

Background and Objective: Overweight is an ailment wherein abundance muscle to fat ratio has gathered to the degree that may contrarily influence health. The motivation behind this examination was to look at between the suitability of activity and acupuncture therapy in diminishing weight of the overweight children.

Materials and Method: Forty overweight offspring of both genders ages went from 9-12 years were arbitrarily separated into 2 gatherings of equivalent number. Youngsters in gathering (I) got practice treatment program and gathering (II) received needle therapy treatment notwithstanding diet therapy for the two gatherings. Exercise treatment program was led for 60 minutes and the needle therapy treatment was directed for 30 minutes. Treatment was directed day after day a week for three progressive months. In Body 270 apparatus was used to assess body weight, muscle to fat ratio mass, all out Absolute body water and midsection hip proportion when three months of intervention.

Results: Significant improvement in weight reduction, muscle versus fat mass, complete Absolute body water and midriff hip proportion was gained in the both groups while there is huge contrast in this values for gathering (II)

(Conclusion: It can be concluded that activity treatment program or acupuncture related to diet therapy program significantly reduced weight in overweight children.

Keywords: *Acupuncture, Muscle versus fat mass, Exercises, Overweight, Absolute body water, Waist-hip ratio.*

Introduction

Overweight can be characterized as an illness wherein abundant fat has aggregated to a degree that wellbeing is adversely influenced. Body mass index is an estimation which is generally used to appraise the commonness of overweight and corpulence inside a populace, and it is determined as weight (kg)/stature squared (m2). Cut off purposes of 25 Kg/m2 and 30Kg/m2 are perceived worldwide as meanings of overweight and heaviness, separately has been demonstrated that BMI is fundamentally related with all out muscle to fat ratio for most of individuals [1].

After BMI is resolved for adolescents and youngsters, it is imparted as a percentile which can be gotten from either a diagram or a percentile calculator. These percentiles express a youngster\'s BMI near with kids in the U.S who partook in national reviews that drove from 1963-65 to 1988-94.since weight and height change during advancement and improvement, as does their association with body strength, a youth's BMI must be deciphered relative with posterity of a comparative sexual orientation and age [2].

Children with BMI underneath the 5th percentile are seen as underweight. Those with a body mass index among between 5th percentile to not exactly the eighty

Corresponding Author:
Mohammed Emad Eldin M. Esmail
MSc in Physical Therapy, Faculty of Physical Therapy, Cairo University, Cairo, Egypt
e-mail: drmohammedemad84@icloud.com

fifth percentile are seen as normal or wellbeing weight kids. The overweight youths are 85th to not actually the 95th percentile. Forceful youths are comparable to or more conspicuous more prominent than the ninety fifth percentile [2].

The commonness of youth corpulence has expanded drastically during the previous decades everywhere throughout the world. Most of corpulence in adulthood has its sources in youth which makes heftiness a pediatric concern and the period when intercessions ought to be finished. Obesity is related with increased expanded dismalness and mortality in grown-up life and several adverse consequences in childhood, for example, insulin opposition, type 2 diabetes, dyslipidemia, polycystic ovarian disorder, aspiratory and orthopedic issue and mental issues. Both hereditary and natural elements assume a job in the evolution of fatness. Nourishment and expanded physical action must be empowered, advanced, and organized to safeguard kids [3].

The impacts of a combined nutritional-behavioral-exercise intervention for childhood obesity had a significant weight loss, diminished BMI, decreased muscle to fat ratio, expanded ongoing physical action and improved wellness, just as diminished aggregate and LDL cholesterol levels, among fat youngsters and adolescents[4].

The impacts of needle therapy on fat people haven't completely illustrated. In China and Asia, the after effects of numerous examinations exploring the utilization of needle therapy for weight control give primer proof of the potential impact of needle treatment on weight decrease. Late investigations have demonstrated that needle therapy can decrease weight of the body in kids with straightforward heftiness, just as lower their percentile weight list (PBMI) and midriff hip proportion (WHR) [5].

Therefore, the point of this examination was to look at exercise efficiency and acupuncture efficiency in overweight kids.

Materials and Method

Study Design: This investigation was an experimental study that was performed at the General Mansoura hospital out-patient clinic of Mansoura, Daqahlia, Egypt. The examination was led from February till June, 2018.

Subjects: Forty overweight kids of the two sexes, with age ranged from 9 to 12 years (mean age: 123.6 ± 11.76 months) participated in this examination Children were incorporated on the off chance that they met the accompanying criteria: (1) Overweight according to BMI-for-age percentile (between 85th and 95th percentile), (2) The ability to walk independently, (3) Normal systolic/ diastolic blood pressure (120/65 mm Hg), and (4) The ability to understand the directions during assessment and treatment. Children were rejected on the off chance that they had: (1) Visual and/or auditory defects, (2) Any medical problems, (3) Sensory impairment and/or [6] Diet therapy. Members were haphazardly separated into two gatherings of equivalent number (Group I and II).

Materials:

In Body 270 apparatus: It has upset the field of (BIA) and is as of now the most developed item in the market. Gold standard body composition method like dual energy X ray analysis are correlated with the percent of 98%. The In body 270 apparatus uses 10 impedance measurements by utilizing two distinct frequencies to gauge the five body segments to give more than 25 parameters important and explicit to body organization. The In Body 270 allows the mentor/wellbeing expert to normally screen the degree of muscle to fat ratio, slender bulk and solid advancement[7]. It was used to quantify body composition just as waist-hip ratio.

Acupuncture Tool: Needle acupuncture is the type of needle therapy that includes infiltrating the skin at anatomical focuses on the body with meager, strong, metallic needles that are manipulated manually. For treatment of obesity, usually 4 –7 auricular needle therapy focuses on one ear are selected in per the patient's symptoms, and the auricular needle therapy needles are embedded using forceps.

Procedures:

Evaluative Procedures: The In body 270 apparatus was used to assess the following parameters pre and post twelve weeks of treatment for both groups:

1. **Body Composition Analysis:**
   a. Weight of body in kilograms (kg). Complete body water (total sum of water in body) in liter (L).
   b. Muscle to fat ratio mass (utilized for putting away abundance energy) in kg.

1. **Waist-Hip Ratio (WHR):** It is the proportion of midsection circuit to hip circumference.

Treatment Procedures: Participants were isolated into two groups of equivalent (20 participants in each) by random assignment (https://www.random.org/).

Group (I): Children in this gathering received diet therapy in addition to the exercise therapy program conducted for one hour in the form of cycling, abdominal exercises, resistance training and electrical treadmill training.

Group (II): Children in this gathering received diet therapy and acupuncture therapy conducted for 30 minutes in the form of abdominal needle therapy and auricular acupuncture held for around 3 days. The aforementioned process was repeated on the other ear after 1–3 days until deemed unnecessary [8].

Data Analysis: Statistical studies were done using (SPSS) version 20 for Windows which defined as package for statistical and social sciences. Descriptive statistics (mean and standard deviation) of the children's ages, weight, water, fat mass and waist- hip ratio were conducted. Paired sampled t-test was used to test statistical contrast among pre and post measures for each group. Unpaired t-test was used to the difference concerning the statistics among both groups before just as after treatment for each variable. Every single measurable were significant at 0.05 level of probability.

Results

When comparing between the pre and post measures, the results uncovered a huge reduction of the entirety measured deliberate factors in group (I) just as in group (II). However, the percentage of improvement in group (II) is bigger than that of group (I)(Table 1).Results revealed a non-huge contrasts among the two gatherings regarding the measured variables before intervention. However, there is noteworthy contrasts among the two gatherings regarding the measured variables after intervention in the sake of group (II) (Table 2).

Table (1). Body composition analysis and ratio of waist to hip in every group.

Variables (Mean±SD)		Weight (Kg)	Body Water (Litre)	Body Fat Mass (Kg)	Waist-Hip Ratio

Discussion

The aftereffects of this investigation demonstrated a huge reduction of each and every estimated variable (weight, body water, muscle versus fat mass and waist hip ratio) in the both groups following twelve weeks of treatment, but for group (II).

It is accepted that needle therapy known as acupuncture attempts to adjust focal sensory system synapse levels by animating peripheral nerves at acupoints. These invigorated nerves at that point convey the sign halfway including to the spinal cord, pituitary and midbrain. Initiated focuses would then be have the option to discharge neurochemicals: endorphins monoamines and cortisol [9].

Using acupuncture may increase the arrival of synapses and may improve mind-set, which, thusly, might prompt improved guideline of food intake. This comes in concurrence with Dung [10] who detailed that that needle therapy may smother hunger by endorphin-instigated diminishes in pressure and discouragement Shiraishi et al. [11] also reported that constructive outcome of standard acupuncture and electroacupuncture is presented on mood by altering serotonin levels that have been observed in treating clinical depression, improving temperament and weight reduction.

The after effects of this examination come in concurrence with Caroli, Burniat, Cole, Lissau, & Poskitt [12] who reported that with balanced low-calorie diets, weight reduction of roughly 0.5 kg/week can be accomplished even over longer periods.

The finding of this examination comes in concurrence with Sothern [6] who compared body composition characteristics between over-weight kids who were participating in physical exercises and the people who were most certainly not. The study declared that in over-weight youngsters who were participating in physical exercises, there is less need to severe dietary restriction in effective weight-loss program.

The noteworthy improvement in overall bod composition analysis and the ratio of waist to hip post treatment for group (I) could be credited to the physical movement that may protect or even increment sans fat mass during weight decrease.

This is significant eventually as sans fat mass generally decides resting metabolic rate, the level of vitality used in rest, which is the best piece of absolute vitality consumption. Thusly, compelling weight reduction is well on the way to happen when a blend of dietary schedule and exercise is prescribed. Physical movement further upgrades negative vitality balance. The more calories are used through physical action, the less serious dietary limitation is required. Also, cooperation in physical action improved mental prosperity and cardiovascular wellness. In particular, physical movement assumes a significant job in the upkeep of weight reduction. Cooperation in acquatic exercises or activities diminished fat levels as this consequently given wellbeing and wellness benefits. weight-bearing errands might be significantly less debilitating and can executed into the program [13].

The huge improvement in group (II) using needle therapy might ascribed to stimulation of the auricular regions associated with the ventromedial hypothalamus that influences the satiety center and prompts improved weight reduction (or diminished gain). Likewise, there have been reports of decreased hunger and longings from patients wearing auricular needle therapy gadgets (press needles, staples, or beads)[5].

Improvement of complete body water, muscle to fat ratio mass, waist-hip ratio and body weight following twelve weeks of treatment for group1 could be ascribed the improvement occurred in energy expenditure by 1000-1500 Kcal per week whereas a caloric shortfall of 500– 1000 kcal every day is usually induced by energy - restricted diets. Addition of exercise to food restriction produces a normal increment in weight decrease of about 1.5 kg in overweight subjects [4].

This agrees with Garrow and Summerbell [14] who found that adding activity to a vitality confined routine may also help to preserve fat-free mass. The meta–analysis indicated that for each 10 kg weight reduction by eating regimen alone, the normal loss of sans fat mass is 2.9 kg in boys and 2.2 kg in girls. At the point When a similar weight reduction is accomplised by exercise joined with dietary confinement, the normal loss of fat–free mass is diminished to 1.7 kg in boys and girls. Resistance exercise may bring about a progressively viable conservation of without fat mass during atimeodf vitality limition than intence exercise result in a more effective preservation of sans fat mass during a time of vitality limitation than endurance training.

Our findings are supported by the findings of Catenacci and Wyatt [15] who found that regular exercise is of crucial importance for successful weight reduction upkeep after a time of weight reduction. Most of the proof originates from nonrandomized weight reduction studies with an observational follow-up. People who effectively keep up weight reduction are characterized by significant levels of physical activity, low fat in diet and high dietary carbohydrate intake, and normal self-checking of weight and nourishment intake.

It is accepted that such insertion of needles in specific points will help, correct, and rebalance the progression of qi (Blood and Body Fluids are the most essential substances that comprise the body of wellbeing and keep up its useful activities) flowing along the energy path ways meridians [16].

Normal auricular dots utilized in the management of weight incorporate “Appetite” and “Stomach” dots (for satiety and completion) and “Shenmen” (for sedation and absence of pain). The vagus, glossopharyngeal, trigeminus, facialis, and branches (the second and third) of the cervical spinal nerves are innervating the auricle. The vagus nerve is thought to interface with cranial nerves and those of the stomach related tract, as these nerves share a typical way to the cerebrum [17].

Conclusion

The consequences of this investigation provided the proof that the combination of physical exercises and/or acupuncture with diet therapy can reduce body heftiness in overweight kids.

Acknowledgement: The authors express their thanks to the administration managers and staff members of Mansoura General Hospital for their co-operation while conducting this study and also they thank all parents and their kids for participation in this examination.

Source of FundingL This study received null special grant from Profit sectors, public agencies of funding or commercial agencies.

Abstract

Aim of the study:-In order to assess to assess impact of dietary habit on urolithiasis patients in Kirkuk city and to find out the relationship between some socio _ demographiccharacteristic (age, gender,) and urolithiasis. A descriptive study of aquantitative design was conducted at Azaditeaching Hospital (Llithotripsy unit) for urolithiasis patients in Kirkuk city from 3rd august 2017 to the 20th of March 2018.a questionnaire format was constructed which contains (51) Demographic data include (6) items, medical data include (5) items dietary habit include (40) items. Statistical analysis was used of 3- likert scale option was used in the rating scale as: (3) for always, (2) for sometimes, and (1) for never. Content validity was determined by presenting the questionnaire to a panel of (10) experts . The data were collected through the interviewing . They were analyzed through the application of descriptive statistical analysis (frequency and percentage) and inferential statistical data analysis (chi-square), T. **test** and ANOVAs . The findings of the study indicated that No (30%) of the patients were in age group between (20_29)-(30-39)years, No(60%) were males, No (77%).

Keyword: *Impact, Dietary habit, Urolithiasis patients.*

Introduction

Kidney stone disease has been a well-known entity for centuries. This has been markedly established by different archeological findings, as well as by writings about painful stone colic and therapeutic trials for stone removal .In ancient centuries urolithiasis was often a disastrous disease, with a catastrophic outcome all too often leading to the patient's death. Examinations of Egyptian mummies have revealed kidney and bladder stone disease. For example, in 1901, the English archeologist E. Smith found a 5,000-year-old bladder stone at the funeral site of El Amrah, Egypt [1] However, he reported only four cases of urolithiasis in thousands of examined mummies, which led to the conclusion that stone disease must have been less prevalent in ancient Egypt. Regimens for treatment of diseases of the urinary tract, including stones, had already been found in the papyrus Ebers (1500 BC), being the main origin of our knowledge of old traditional Egyptian medicine. Although the ancient Egyptians were famous for their mummifying techniques, they obviously did not know how to remove kidney or bladder stones[2] Urolithiasis is one of the most common diseases with approximately 750,000 cases per year in Germany. While most patients have only 1 stone episode, 25% experience recurrent stone formation. Thus, urolithiasis has a significant impact on life quality and socioeconomic factors[3] Several groups have reported a worldwide increasing incidence and prevalence, which seems to be more pronounced in industrialized countries. Clinical observations indicate a changing incidence and composition of urinary calculi as well as a dynamic of gender and age related incidences[4] Urolithiasis is a significant source of morbidity, affecting all geographical, cultural, and racial groups. The lifetime risk is about 10- 15% in the developed world, but can be as high as 20-25% in the Middle East. The increased risk of dehydration in hot climates, coupled with a diet that is 50% lower in calcium and 250% higher in oxalates

Corresponding Author:
Qasim Hussein Mohammed
Department of fundamentals Nursing, College of Nursing, University of Kirkuk, Iraq

compared to Western diets; accounts for the higher net risk in the Middle East. Although one might expect more calcium oxalate stones, uric acid stones are actually more common in the Middle East than calcium-containing stones[5] Urinary stone is an increasing disease due to the changes in nutritional behavior and in the general life style. Urolithiasis is manifested by the repeated medical symptoms and potential cause of structural harmful of the renal and of the urinary system in addition to the potential enhance in systemic blood pressure. Furthermore, numerous need for medical treatment and invasive urological procedures increase the patient's exposure to adverse effects of these managements[6]

Specific objectives of the study:

1. To assess impact of dietary habit on urolithiasis patients in Kirkuk city .
2. To find out the relationship between some socio _ demographic characteristic (age, gender,) and urolithiasis.

Methodology

To achieve the objectives of the study quantitative design (descriptive study) was conducted on urolithiasis patients from 3rd August 2017 up to the 20th of March 2018 . To assess impact of dietary habit on patients with urolithiasis at Azadi teaching hospital in Kirkuk city.

Setting of study the study was conducted at Azadi teaching hospital in Kirkuk city, which are receiving large number from urolithiasis patients.

The Sample A non-probability (purposive) sample of (100) patients definitely diagnosed with urolithiasis who were attended to the Lithotripsy unit at Azadi teaching hospital. Through extensive review of relevant literature, a questionnaire was format constructed for the purpose of the study with interview technique. Overall items included in the questionnaire were (51) items, demographic data include (6) items, medical data include (5) items diatary habit include (40) items. 3- likert scale option was used in the rating scale as: (3) for Always, (2) for Some time, and (1) for Never .

Validity of study content validity was determined by presenting the questionnaire to apanel of (10) experts in different specialties three physicians experts in urology surgery, three experts in adult health nursing, three experts in internal medicine,one expert in statistic. Those experts were asked to review the questionnaire for content clarity, relevancy, and adequacy .Their responses indicated that minor changes should be performed on few items. All modifications were made relative to their recommendations .

Data collection the data collection process was performed from the period 10th August 2017up to the 19th of December 2017 .

Data Analysis: The collected data were analyzed through the application of descriptive statistical analysis (frequency and percentage) and inferential statistical data analysis (chisquare), T. **test** and ANOVAs.

Results and Discusion

Table 1 indicates that the mean of score was low significant in items (2,6) and moderate significant in items (4,3,7) and high significant in items (1,5,8,9,10). Table 2 indicates that the mean of score was low significant in items (5,10) and moderate significant in items (1,2,3,6,8,9) and high significant in items (4,7,11,12). Table 3 indicates that the mean of score moderate significant in items (1,2,3,4). Table 4 indicates that the mean of score was low significant in items (1,4,5,6) and moderate significant in items (2,3). The results shows urolithiasis is common in male and constituted of (60.0%) . The study reveals that (68%) of the study sample were male, these results supported by Soller (2004) who stated that the occurrence of urolithiasis is more common in male than female by the ratio of 1.3[(8)]With regard to residence (78.0%) were living in urban areas, the explanation of result related to the place of Azadi teaching hospital in center of governorate there for receive large patients number from urban area, Also result show most of the patients were married and constituted (77.0%) These findings agreed with the common idea ‘’the most inflammations leading to infection ‘’the close partner (husband) the best transmitter for diseases and primarily uro-genetical tract organs is a good route and area for bacterial growth (Dark and moist area), and personal bad hygiene.With regard to occupation (31.0%) of the sample were free work Such people are busy to use water circulation. Such obligatory delay from urination would mostly lead to stone formation. This finding agreed and similar to the results of Al-Kaabee who stated that the large frequency of study sample is employed [(9)] with regard to the educational level (31.0%) of the sample were primary school graduates . this mean the most of patients were in low level of education, Patient level of education play

important role in identify the risk factors for recurrent urinary stone and preventive measures for stone formation. Table (1) demonstrate the medical data and shows duration of complaint were between (1-4 years) and represent (42.0%) while (51.0%) from patients were take treatment for less than one year, Muhbes (2012) stated that many patients will be experienced anumerous stones during their age, with expected return rates of half of them within 5–10 years and 75% within 20 years[10] with regard to the stone site (93.0%) from patients were have stone in kidney . (63.0%) from patients were free from other disease because of large number from patients were between 20-29 years there for free from disease, with regard to the history of stone removed (73.0%) from total patients were have history for stone removed. The result shows (53.0%) from total sample were have family history for urolithiasis. The picture could be seen from a window that the effectiveness of the life habits is similar in each family. Al-Kaabee supported this result, he found that people with family history of urinary tract stone at higher risk than those without relatives having stone formation [9]Table (2) of Animal sourcethis table indicates that the mean of score was low significant in items (2,6) and moderate significant in items (4,3,7) and high significant in items (1,5,8,9,10). Table (3) shows large number of sample eating a large quantity of red meat, liver and tuna. Johri agree with this result, who said; that urinary citrate excretion is commonly found in those with a high dietary intake of animal protein, whereas vegetarians tend to have higher levels of citrate excretion. So is high intake of protein is dangerous for SF [11]

Table (1): Mean of Scores for Other substance items with frequency, percentage and severity and Chi-square.

No.	Other substance	Always		Some time		Never		MS	Severity
		F	%	F	%	F	%

Conclusion

The result shows the high percent of patients were between (20-29years) (30-39 years)and constitute (30%). Also the results shows urolithiasis is common in male and constituted of (60.0%). Most of the patients were married and constituted (77.0%) and (31.0%) of the sample were free work with regard to the educational level (31.0%) of the sample were primary school graduates. Most of the samples were complaint from kidney stone between (1-4 years) and represent (42.0%) while (51.0%) from patients were take treatment for less than one year. The study concluded large number from study sample were take large quantity from red meat, tuna, drink tea and beverage. The study concluded most of the study sample were not drink water in sufficient amount. Also the study concluded that there is minor significant relationship between urolithiasis and age, gender of patients.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of fundamentals Nursing, College of Nursing, University of Kirkuk, Iraq and all experiments were carried out in accordance with approved guidelines.

Test Anxiety in Terms of the Test Wisdom and Learning Patterns of Students in Faculties and Departments of Physical Education and Sports Sciences

Aied Kareem Abdaun[1], Hassanienabdilwahidabbas[2], Mustafa Jasimabdzaid[3]

[1]AL-Qasim Green University–Iraq, [2]AL-Qasim Green University–Iraq, [3]AL– Almustaqbal University College–Iraq

Abstract

The study aimed to identify the level of test anxiety and the test Wisdom and the pattern of the prevailing learning for students of faculties and departments of Physical Education and Sports sciences at the universities of Al-furat Al-Awsat, and the study tool was 3 measures, the test anxiety consisted of (36) paragraph divided by (3) dimensions and the test Wisdom consisted of (38) paragraph divided by (6) dimensions and the List of Kolb consisted of (9) positions each position consists of (4) options, while the number of sample application (217) student, the most important findings of the study are the controlled and validation of test anxiety measurements and test Wisdom as well as knowledge of the sample level on both scales either The most important recommendations were the adoption of standards as a criterion for identifying students at the level of test anxiety and test Wisdom patterns.

Keywords: *Test anxiety, Test Wisdom, Learning patterns.*

Introduction

With the increased use of tests and their role in the life of the individual scientific and practical, the need to possess skills and strategies emerges to help the student to provide tests in an effective and comfortable manner, and to possess the test Wisdom helps the student to reduce the anxiety associated with the test and develops positive attitudes towards the tests in general and towards the subjects in which these tests are conducted.

The tests are supposed to be an honest tool to treat fairly the student and grant her right, and to measure their abilities, knowledge and skills in subjects, and it's supposed that the difference between the students in their test results is due to their abilities in the field of school subject, but it is easy to discover all teaching through feedback of the tests, the wisdom of the student to answer or the test Wisdom can be an important factor in preventing this purpose, as some students complain that they do not get grades equivalent to their understanding and readiness while others show their satisfaction with grades compared to their preparation and their readiness. This is evidence that test Wisdom represents a source of variation in grades. The test Wisdom skills are found in a group of students who are used to answer questions that they do not know by using the skills of guessing or taking advantage of the mistakes of those who put the test, which are indicators and stimuli for the student to be useful in guessing and anticipating the correct answer and appear clearly in the tests (multiple choice questions, pairing, true and false), and it should not be understood that having such skills and strategies is sufficient for the student to succeed without the readiness, understanding and preservation of lessons as well as without having the necessary knowledge to provide the test, The importance of research in addressing the variables of test anxiety and the test Wisdom and learning pattern. Knowing of the test Wisdom strategies in terms of a particular learning pattern may help students create an environment that reduces test anxiety.

Methodology

Determining the method of drafting the test anxiety and test Wisdom scales and their bases: It is a good test that uses a variety of method to accurately measure what is placed for it, so researchers have used the Likert method to prepare the two scale articles.

Preparation and compilation of test anxiety and test Wisdom articles

Preparation and compilation test anxiety articles: The Researchers looked at several measurements and references that have addressed the test anxiety as a study[1-10]. The researchers looked at several measurements and references that have addressed the test anxiety as a study [11-14] The researchers prepared the instructions and took them to be clear; pointing out that what the researchers get is for the purposes of scientific research, as the answer instructions contained in the Search tool are a guide for the respondent.

Implementation of the conditions for conducting of the two scales: The researchers tried to adjust the internal factors to ensure the safety of the procedure as much as possible and ensure that the instructions are clear-meaning to simplify the process of testing performance and achieve the desired goal.

Conduct the two- scales experiment and the Kolb list of learning patterns: After you have prepared and compiled the scales articles, the main step is to experiment of scales and consist of:

The Exploratory experiment: The researchers conducted their exploratory experience of the test anxiety and test Wisdom scales as well as Kolb's list of learning patterns on 25/12/2017 at 9 a.m. on a sample of 19 students, selected in the stratified random from the research community, and the results were encouraging towards the Measurement tool.

The main experiment: The researchers began their main experiment on 3/1/2018, on the controlled sample (97) students, to analyze its articles statistically by using (two-group), where each terminal group represented (27%) The number of (26) students per group during the period between (3/1 to 15/2/2018) and under the same conditions and instructions. The researchers collected the data for the members of the controlled sample, arranging them in tables for statistical analysis.

Correction of test anxiety and test Wisdom scales: The total grade was extracted and the lowest grade got it tested for the test Anxiety scale is (36) and the highest grade is (180) and the hypothetical median is (108), as for the Test wise scale, the lowest grade got it tested is (38) and the highest grade is (190) and the hypothetical median is (114).

Statistical analysis of test anxiety and test wisdom scales

Researchers have followed the following method:

Extract the coefficient of discrimination for the test anxiety scale

To extract it follow the following steps:

Two terminal groups: The total grades were divided into two maximum and minimum sections, and like each section (26) a student of the controlled sample (97) All of the scale articles were found to be distinctive, with the arithmetical median of the minimum group ranged between (1.00) and the standard deviations between (0.01) and the maximum group ranged from (5.00) and the higher deviations between (0.02) below the level of significance (0.05) and the degree of freedom (50).

Extraction of the coefficient of distinction for the test wisdom scale

To extract it, the researchers followed the following steps:

Two Terminal Groups: The total grades were divided into two maximum and minimum sections, and like each section (26) a student of the controlled sample (97) All of the scale articles were found to be distinctive, with the arithmetical median of the minimum group ranged between (1.00) and the standard deviations between (0.03) and the maximum group ranged from (5.00) and the higher deviations between (0.06) below the level of significance (0.05) and the degree of freedom (50).

The Internal Consistency: The higher the degree of correlation coefficient of the sub-tests in the total grade of the test as the internal consistency of the test as a whole is indicated and internal consistency has been achieved through the following indicators:

Internal consistency of the test anxiety scale:

Coefficient of correlation between the degree of the paragraph and the total degree of scale: The researchers used the Pearson correlation coefficient between the degree of the paragraph and the total degree of scale where its value ranged from (0.60 – 0.39) which is significant below the level of significance (0.05) and degree of freedom (98).

Correlation coefficient between the degree of the paragraph and the total degree of the dimension: The researchers used the Pearson correlation coefficient between the degree of the paragraph and the total degree of the dimension, where the first dimension ranged between (0.55 – 0.37) and the second dimension (0.57 – 0.37) and the third dimension (0.60 – 0.39), which is significant below the level of significance (0.05) and degree of freedom (98).

Correlation coefficient between the degree of dimension and the total degree of scale: The researchers used the Pearson correlation coefficient between the degree of dimension and the total degree of scale, which ranged between (0.81 – 0.86 – 0.88), which is significant below the level of significance (0.05) and degree of freedom (98).

Internal consistency of the test wisdom scale

The Statistical Method: Researchers used Statistical Package for the Social Sciences (SPSS)

Results and Discusion

The forms were corrected (233) and 16 of them were excluded from the failure to complete the answers of the members of the sample application, so the sample consisted of (217) students. In order to identify the prevalence of the test anxiety and test wisdom scales, the arithmetical media and standard deviation have been extracted table1.

Level of test anxiety and test wisdom patterns: Three standard levels of the test anxiety were identified, with different rates, where the level of anxiety was low (15.73) and average anxiety (68.27) while the level of anxiety was high (15.73), and five levels of the Test wisdom scale were very weak and very good (4.862) While the two levels were weak and good (24.522) and the average level was (40.962). The table 2. For the test anxiety scale, the prevailing level was (average anxiety) by (58.53) of the area under the normal distribution curve and by the number of (127) students and achieved degrees ranged between (100-138) degrees on the scale.

The test wisdom scale was the prevailing level (average test wisdom) of (43.78) of the area under the normal distribution curve and of the number (95) of students and achieved degrees ranged between (130 - 149) degrees on the scale.

Identify the patterns of prevailing learning among female students of faculties of physical Education and sports sciences: In order to identify the method of prevailing Kolb among students of faculties and departments of Physical Education and sports sciences it appeared that the divergent method represented by (44) student, the Convergent method represented by (70) student, the comprehension method represented by (64) students and the adaptive method represented by (39) students.

Identify the relationship between the test anxiety scales and the test wisdom patterns: In order to identify the relationship between the test anxiety scales and the test wisdom of the students of faculties and departments of Physical Education and sports Sciences, the numbers shown in the table 3.

Table (1): Showing level of test anxiety and test wisdom scales

Test Anxiety Scale				
Categories - Levels		**61 – 99 Low anxiety**	**100-138 average anxiety**	**139-177 High anxiety**
Standard (ideal ratios)		15.73	68.27	15.73
Achieved Number	Test anxiety	50	127	40
%		23.04%	58.53%	18.43%

Test Wisdom Scale						
Categories - Levels		**90-109 Very weak**	**110-129 weak**	**130-149 average**	**150-169 Good**	**170-189 Very good**
Standard (ideal ratios)		4.862	24.522	40.962	42.522	4.862
Achieved Number	test wisdom	15	50	95	44	13
%		6.91%	23.04%	43.78%	20.28%	5.99%

Table (2): Shows the relationship between test anxiety and test wisdom patterns and the Kolb's list of learning patterns

	The Sample	Correlation Coefficient		Significance Level		Statistical Significance	
		Test Wisdom	Learning Method	Test Wisdom	Learning Patterns	Wisdom	Patterns
Test Anxiety	217	0.49	0.10	0.001	0.17	Significance	Non-Significance

Table (3): Shows the results of the analysis of the variance of the test anxiety scale by the variable of educational stages

Source of Variance	Total Deviations	Degree of Freedom	Average Deviations	Calculated F Value	Sig	Statistical Significance	Kolb Method
Between Groups	1314.694	3	438.231	1.886	0.048	significance	Convergent
Within Groups	9296.033	40	232.401				
Between Groups	3220.620	3	1073.540	2.001	0.022		Divergent
Within Groups	35403.323	40	536.414				
Between Groups	933.044	3	311.015	0.568	0.638	Non significance	Comprehension
Within Groups	32867.393	40	547.790				
Between Groups	2367.134	3	789.045	1.589	0.029	significance	Adaptive
Within Groups	17376.097	40	496.460				

Conclusion

Through the fourth chapter of the presentation, discussion and analysis of results, the results showed: The possibility of validation the test anxiety scales and the test wisdom patterns for students of faculties and departments of Physical Education and sports Sciences. The prevailing level of test anxiety and test wisdom was the average level of students in faculties and departments of Physical Education and sports Sciences. There is no relationship between test anxiety and the test wisdom patterns of students in faculties and departments of Physical Education and sports Sciences. Predictability of test anxiety in terms of test wisdom and kolb's learning patterns.

The Diagnosis in Terms of the Cognitive Assessment System (CAS) for the Intelligence of the Sample of People with Special Needs

Mahdi Mahdi Hassan[1], Haydar Tarek Kazem[1], Haider Hatem Al Ajrash[1]

[1]University of Babylon/Faculty of Basic Education/Special Education, Iraq

Abstract

The current research aims at diagnosing students with special needs (learning difficulties, slow learning, mentally handicapped, learning disabilities, distraction/hyperactivity). Where the descriptive approach was used in the current research. The sample of the study consisted of (100) students and students who are present in primary schools in the center of Babil governorate in the academic year 2019-2018 and between the ages of 10-6 years. Cognitive Assessment (CAS), which includes four basic knowledge processes (planning, attention, carefulness, sequencing), each of which has three sub-tests, and after verifying reliability and consistency, the data were collected and analyzed by using arithmetical averages, standard deviations. The results of the study indicate There are statistically significant differences among students with special needs, the four mental processes and in the light of these findings the researcher recommended that more research and studies using the variables of this research with one or more categories of special education classes.

Keywords: *Diagnostic, diagnostic battery (CAS) for intelligence, people with special needs.*

Introduction

The school is the second social institution that contributes to the formation of young people. The main objective of the school is to reach the students for the best possible performance through accurate and good diagnosis that stands on the strengths and weaknesses and tries to improve the strengths and address deficiencies in their performance. This is to determine educational programs and appropriate enrichment for each individual, and applied in a procedural manner to develop the educational process in a positive way[1], and the diagnosis is through the tests provided to the individual, and based on the person shows the correct responses are the degree Wei DD level, ie that these tests are interested outputs that appear through the performance[2]. Diagnosis and evaluation are among the main issues in the field of special education, for several reasons, the most important of which is the use of measurement and evaluation tools to identify the cases of unusual children and diagnose them as a differential diagnosis and turn them into educational and therapeutic programs and services commensurate with their abilities and potentials [3].A number of studies, including Shosha (2001), have pointed out that diagnosticians of special needs use psychometric measures of intelligence that focus in particular on one factor, abstract intelligence (general), which is contrary to the work of mental processes and cognitive functions of the brain in terms of Vigilance, planning, deliberation and sequence, which makes this diagnostic and measurement process incomplete and inaccurate at all[4]. Because there is no precision in diagnosing the difference and in assessing the performance of students with special needs, although there are many measurement tools that consider measuring intelligence as a single unit, it is based on the degree obtained by the examinee (which represents the level of intelligence in general). In the classification or

Mahdi Mahdi Hassan
University of Babylon/Faculty of Basic Education/ Special Education, Iraq
e-mail: ha4967705@gmail.com

diagnosis of people as special needs, and in many cases rely on the evaluation of teachers as a tool for diagnosis, which can not be relied upon for several reasons, including the few experience in this area and objectivity, and here must be identified method of effectiveness and efficiency In diagnosing metabolic problems Amzh with special needs [5].In order to overcome the problems facing traditional diagnostic method, the Cognitive Intelligence System (DAS), which was developed by Das to measure intelligence through PASS, attempted to accurately define the four basic cognitive processes that occur within the brain and are responsible for input processing. Where the importance of the current research stems from the need for the diagnosis of students with special needs and special importance in the field of psychology in general and private education in particular, as this research employs the battery of cognitive assessment of intelligence (CAS) in the measurement, diagnosis and evaluation of these students and according to their categories Which facilitates easy scientific and practical work The brain is the center of the learning process. It also controls the patterns of learning and thinking. Thus, the knowledge of brain functions is essential for educators and practitioners. The brain hemispheres can be divided into four main sections Called lobes. These lobes are not differentiated units, but anatomical regions, each of which has specific functions but is interactive and integrated. The four cerebral lobes of the hemispheres can be illustrated as follows: The knowledge of the functions of the brain hemispheres helps the educators and the learning process to understand the learning process and thus can diagnose and evaluate students with special needs through the knowledge-based cognitive assessment system (CAS) based on PASS theory (Ibrahim, 2012: 23).

Methodology

The researcher used the descriptive approach in this research because it is the appropriate method for the nature of the research and its objectives.

Community Search: The research community consists of (720) students and students in the special education classes from the first stage to the fourth stage distributed in (40) primary schools where there are special education classes 420 students and 300 students, as indicated by the Department of Educational Statistics in the General Directorate of the province of Babylon.

Sample Search: The researcher selected the research sample by class method, four categories of special education (learning difficulties, slow learning, mentally handicapped, learning disabilities, distraction/ hyperactivity) and 25 students per class.

Search Tool: In order to achieve the current research objectives in the detection of students with special needs (learning disabilities, slow learning, mentally handicapped, learning disabilities, distraction/ hyperactivity), the researcher used the cognitive assessment system (CAS) to assess children aged 5-17 years where the battery of the four cognitive processes (planning - attention - careful - relay) and each of these processes include three sub-tests and give a score of 10 and a standard deviation (3(.

Psychometric Characteristics of the Knowledge Assessment System: Psychometric characteristics are used in educational and psychological research as indicators of the accuracy of standards. The extraction of honesty and persistence is one of the most important characteristics. Therefore, the researcher undertook a number of procedures to extract honesty and consistency, as follows:

A Virtual Honesty: The honesty is a kind of honesty required in the construction of tests and measurements, and this kind of honesty refers to the appearance of the test and how it seems appropriate for the purpose for which it was developed and uses this kind of honesty to conduct preliminary examination of the contents of the test. Ebel (2009) states that the preferred method of checking the veracity of the instrument of measurement is that a number of competent experts determine the veracity of the paragraphs to measure the degree to which they were established. In accordance with the verification of this type of honesty, the paragraphs of the standard were presented to the Committee of Experts with specializations in special education and psychology. The researcher asked each one of them to indicate about each paragraph in terms of being valid or invalid, or need to be modified with The proposed amendment was mentioned. The researcher adopted a point of agreement of the experts on the validity of the paragraph is (80%) if the agreement on the validity of equal or higher than the point of agreement depends paragraph, although less than rejected or adjusted according to the observations of the Committee of Experts.

A box to determine the percentage of expert approval for the validity of the scales of the cognitive assessment

system for intelligence. The value of the square of Kai is a function of all the paragraphs. The value of Ka 2 is greater than the value of Ka 2 at the degree of freedom (1) and the level of significance (0,05).

Construction Certifications: The researcher was able to apply the equation of the Pearson test coefficient after the data collection and analysis by means of the statistical method SPSS in order to find the relation of each paragraph of the scale in the overall degree.

The coefficient of excellence: Is the ability to distinguish between the upper and lower categories. And to distinguish between individuals who obtain high grades and individuals who obtain low grades in the measured attribute in the sense that the distinction of the paragraph is consistent with the distinction of the test (Ebel, 1972: 399). To extract the coefficient of discrimination, the researcher used the coefficient of discrimination by the two extreme groups, The results ranged between (21-46) and lowest (27%), ranging between (8-26) of the correct answers on the test paragraphs by (50) in each group to become the total number (100) students and students. Discrimination using the discrimination equation and the table below illustrates this.

Reliability: Stability is a cykometric property that must be verified to demonstrate the validity of the scale as well as honesty, making it more robust and robust. The validity of the measurement depends on the degree of stability of its results. The constant measure yields the same results almost if the same property is measured in successive times.There are several method to calculate stability, and the researcher used the following method to extract stability:

A. **Test Retest Method:** The stability of the cognitive assessment system was obtained by re-applying the scale to the sample of the students examined, consisting of (50) students and students with special needs. The scale was applied again 15 days after the first application. The students' degrees in the first and second applications using the Pearson correlation coefficient and the stability coefficient value of the total scale (0.90). This value is good and indicates the high stability coefficient of the cognitive evaluation system scale.

B. **Split Half Method:** The stability coefficient of the scale can be predicted if we can find a half-stability coefficient. Therefore, the researcher extracted the stability in the half-split method of the system scale.By dividing the paragraphs of the scale into individual and odd paragraphs to verify the validity of the internal consistency of the scale. The correlation coefficient was calculated between the individual and the pair. The coefficient of stability was determined using Pearson correlation coefficient (0.84) The stability obtained by using the Spearman-Brown equation to find the value of the stability coefficient of the scale as a whole. The stability value after correction (0.91) is a good indicator and expresses a strong and high relation to the total stability coefficient of the scale.

Statistical Means: The researcher used the SPSS program to extract the results of his research and used the following tools:

A square as: to extract the virtual truth of the scale.

B Pearson correlation coefficient of stability.

The Spearman-Brown Act was used to correct the Pearson correlation coefficient.

W Test of correlation coefficient.

Results and Discusion

After the extraction and analysis of data in the program of statistical truthfulness SPSS results were reached according to the objectives of the research as follows: The objective is to find the differences of statistical significance for students with special needs (learning difficulties, slow learning, mentally handicapped, learning disabilities, excessive attention/ activity)Based on: A planning process. B. Attention process. The process of delay. W The relay process. To achieve this goal, the researcher used the multivariate analysis test and the following results were obtained: It is clear from the above table that people with learning disabilities and mentally disabled are demoted because the level of significance is less than 0.05 and the slow learning and attention distraction is D because the level of significance is higher than 0.05. In order to follow the differences, the researcher used L. S. D test the least significant difference, and obtained the table 3.

Table 1. The multivariate analysis test

Source of Contrast	Total sum of squares	The degree of freedom	Average quadrature	The F Value	Level of significance
Functions	3286.558	3	1095.519	73.244	0,000

Mentally Disabled	Planning • Attention	10.33	.000	Not a function in favor of planning
	Planning • Carefulness	63.	.433	Not a function in favor of planning
	Planning • Relay	97.	232.	

Conclusion

The results of the study indicate There are statistically significant differences among students with special needs, the four mental processes and in the light of these findings the researcher recommended that more research and studies using the variables of this research with one or more categories of special education classes.

The Duration and the Severity of Menstrual Bleeding in Iraqi Women Using Intrauterine Contraceptive Device (IUD): Cross Sectional Study

Makkiyah Radhi Lateef

Gynecology Specialist/Al-Diwaniyah Child and Maternity Hospital/
Department of Obstetrics and Gynecology/Al-Diwania/Iraq

Abstract

The objective of this study was highlight the adverse side effects associating the use of IUD in terms of severity and duration of menstrual bleeding and their correlation to a number of demographic characteristics such as age, residency, occupation and past obstetric history in addition the correlation to duration of use of IUD.52 women with IUD were enrolled in this cross sectional study that was carried out in some governmental and nongovernmental obstetric institutes in Al-Diwaniyah province, Mid-Euphrates region, Iraq. The study stared one January 2018 and ended on March 2019. The main outcomes were the severity and duration of menstrual bleeding. The mean duration of intrauterine contraceptive device (IUCD) was 2.39 ± 1.91 years and the duration ranged from one month up to 7 years. The duration and the severity of menstrual bleeding are shown in table 2. Four women (7.7 %) had 2-4 days/cycle duration of menstruation, 13 women (25.0%) had 4-6 days/cycle duration of menstruation and 35 women (67.3 %) had > 6 days/cycle duration of menstruation.

Keywords: *IUCD, duration, severity, menstrual bleeding.*

Introduction

In spite of the fact that up to 15 % of couples will suffer subfertility worldwide [1,2], almost all the rest of couples (85 % or more) will use some method of contraception at some point of their reproductive lives in order to control family number [3-5]. The use of contraceptives is both beneficial for the prevention of unplanned and unintended pregnancies [6,7] and for control of some symptoms associating natural menstruation such as pain and bleeding [8,9] as well as to reduce the risk of ovarian and endometrial cancer [10,11]. There several method to prevent pregnancy including hormonal and non hormonal based method. Among the long list of contraceptives, the well known method included oral contraceptive pills, injectable contraceptives, intrauterine devices, vaginal rings and patches. These were the hormonal based method; the non hormonal techniques included copper based intrautetrine devices, diaphragm and condoms [12]. None of these, hormone based and barrier method is free of side effects and complications [13-17]. Intrauterine contraceptive devices, whether hormone or cupper based, are still among the most commonly used contraceptive method by women in their reproductive age [15,16]. However, IUD is frequently associated with adverse complications such as long duration of menstrual bleeding, heavy menstrual bleeding, infection, expulsion and perforation [18,19]. It has been reported that a number of women with IUD have decided to remove the device because of heavy and or prolonged menstrual bleeding [20]. Some forms of IUD particularly cooper containing ones are said to be associated with heavy menstrual bleeding at the beginning of its usage that lasts for a couple of months and then women get used to it and satisfactory because of reduced amount and duration of bleeding [20]. Sufficient controversy existed in

Gynecology specialist/Al-Diwaniyah child and maternity hospital/Department of Obstetrics and gynecology/Al-Diwania/Iraq

published articles about side effects and complications associating the use of IUD and about the correlation of these adverse side effects to a number of demographic characteristics, ultrasound findings and duration of IUD usage [21]. Moreover, Iraqi literatures dealing specifically with duration and severity of menstrual bleeding accompanying the use of IUD are usually of small sample size and of controversial opinions [22,23]. Therefore, the current study was planned and conducted to include as much as possible a significant number of women using IUD and various duration of usage, in the Mid-Euphrates region of Iraq at Al-Diwaniyah province. The objective of this study was highlight the adverse side effects associating the use of IUD in terms of severity and duration of menstrual bleeding and their correlation to a number of demographic characteristics such as age, residency, occupation and past obstetric history in addition the correlation to duration of use of IUD.

Methodology

This cross sectional study was carried out at some governmental health institutes such as Al-Diwaniyah Maternity and Child Teaching hospital and Al-Shamiyah teaching hospital and some private clinics. The beginning of the study is dated back to the 2nd of January 2018; the study continued till end of March 2019 and included 52 women. Inclusion criteria included any women with IUD with no limitation for the duration of use so that women with as long as 7 years and women with as short as one month duration of use were included in the study. The questionnaire form included age, duration of IUD, parity, abortions, residency, occupation and characteristics of menstrual bleeding. The severity of menstrual bleeding was categorized as light (< 10 pads per cycle), moderate (11-20 pads per cycle), heavy (21-30 pads per cycle) and very heavy (> 30 pads per cycle), whereas, the duration menstruation was grouped into: 2-4 days, 5-6 days and > 6 days (24). The study was approved by the institutional approval committee and verbal consent was obtained from all participants following full illustration of the aim and procedures of the current study. Data were then transformed into an SPSS (version 23) spread sheet. Numeric data were expressed as mean, standard deviation, median, inter-quartile range (IQR) and range, whereas, categorical data were expressed as number and percentage. Correlation was calculated using Spearman correlation test and the level of significance was chosen at $P \leq 0.05$.

Table 1: Characteristics of menstruation

Duration of Menstruation	**n**	**%**
2-4 days/cycle	4	7.7
5-6 days/cycle	13	25.0
> 6 days/cycle	35	67.3
Severity of Bleeding	n	%
Light (< 10 pads)	18	34.6
Moderate (11- 20 pads)	5	9.6
Heavy (21- 30 pads)	18	34.6
Very heavy (> 30 pads)	11	21.2

Table 2: Correlations of bleeding severity and duration to demographic characteristics and duration of IUCD

	Severity		**Duration**	
Characteristic	**r**	**P**	**r**	**P**
Age	0.078	0.584	0.090	0.526
Occupation	-0.040	0.778	-0.201	0.152
Parity	0.096	0.497	0.148	0.297
Abortion	0.098	0.490	0.204	0.146
Residency	0.111	0.433	0.185	0.188
Mode of previous deliveries	0.214	0.103	0.178	0.207
Duration of IUCD	0.019	0.908	0.129	0.363

Table 3: Ultrasound findings

Ultrasound Findings	n	%
Bulky uterus	4	7.7
Liomyoma	2	3.8
Thick endometrium	2	3.8
Ovarian cyst	1	1.9

Results and Discusion

Demographic characteristics of the study sample are shown in table 1. This study included 52 women with IUCD with a mean age of 29.83 ±7.13 years and an age range of 17 – 44 years. According to parity the study included 22 (42.3 %) and 30 (57.7 %) women who were low multiparous (parity = 1-3) and grand multiparous (parity > 3); median parity was 4, the inter-quartile range was 3 and the range was from 1 to 8. Participants were categorized according to abortion into: 37 (71.2 %), 3 (5.8 %), 4 (7.7%), 7 (13.5%) and 1 (1.9%) as having no previous abortion, single, twice, three and 4 times previous abortions. With respect to mode of delivery, women were classified into: 27 (51.9 %) women with all previous deliveries happened through normal vaginal route, 11 (21.2 %) women who delivered all their babies by cesarean section only and 14 (26.9 %) women who have delivered some of their babies normally through vaginal route and the rest of their babies by cesarean section. The study included 31 (59.6%) women from urban areas and 21 (40.4%) women from rural areas. The study enrolled 32 (61.5%) women who were employed and 20 (38.5%) women who were housewives. The mean duration of intrauterine contraceptive device (IUCD) was 2.39 ± 1.91 years and the duration ranged from one month up to 7 years. The duration and the severity of menstrual bleeding are shown in table 2. Four women (7.7 %) had 2-4 days/cycle duration of menstruation, 13 women (25.0%) had 4-6 days/cycle duration of menstruation and 35 women (67.3 %) had > 6 days/cycle duration of menstruation. On the other hand, 18 (34.6 %) women experienced light bleeding, 5 women (9.6 %) had moderate bleeding, 18 (34.6 %) women described heavy bleeding and 11 (21.2 %) women complained of very heavy bleeding. Age, occupation, parity, abortion frequency, residency, mode of labor and duration of IUCD showed no significant correlation to severity or duration of menstrual bleeding (P> 0.05), table 3. Ultrasound examination revealed the presence of bulky uterus in 4 cases, submucosal liomyoma in 2 cases, thick endometrium in 2 cases and ovarian cyst in a single case as shown in table 4.Among the list of adverse effects and complications associating IUCD, long duration and heavy menstrual bleeding remain among the most frequent causes that necessitate the removal of the contraceptive device by significant proportion of women (22, 23).In this cross sectional study, a significant number of women experienced heavy or very heavy menstrual bleeding accounting for 55.8 %. On the other hand 67.3 % of them had relatively long duration of menstruation of > 6 days per cycle. Therefore more than half of women enrolled in the current study had a bad experience of long and heavy menstrual bleeding associating the use of IUCD. We aimed to link the severity and the duration of menstrual bleeding to some demographic characteristics such as age, residency, occupation and past obstetric history or to the duration of IUCD use; however, we failed to obtain a significant correlation. For that reason, we suppose that the use of IUCD by itself is associated with heavy and long menstrual bleeding regardless of the duration of use or any other demographic characteristic. Current study revealed the existence of bulky uterus, thick endometrium, submucosal liomyoma and ovarian cyst in a minority of patients; however, these causes may contribute very little to the problem of bleeding severity and duration since they were seen in very small fraction of enrolled women and that more than half of women were suffering heavy and prolonged menstrual bleeding.

Conclusion

Significant proportion of Iraqi women using IUD suffer from long and heavy menstrual bleeding that are unrelated to duration of use.

The Effect of Analysis of Partial Experimental in Expression and Creative Thinking for the Students

Sattar N. Al-Shaibawee[1], Hamzah H.M. Al-Sultani[1], Duraid M.D. Al-Rawdhan[1]

[1]University of Babylon, College of Basic Education, Iraq

Abstract

The researcher adopts the method of partial experimental research as a methodology for his research procedures. To achieve this goal, the researcher has used the following zero hypothesis (there is no significant difference in (0,05) between the average achievement of the students of the experimental group who study the subject of expression according to the analysis of the Quranicsimile and the average achievement of the students of the control group who study the same subject in the traditional method). The researcher randomly selected (Afaksecondary school for boys) as a sample to conduct his research, and in the same way chose Division (A) to represent the control group, the number of students (30) thirty-one students, and (B) to represent the experimental group, the number of students (30) thirty students, the number of students in the research sample (60) students. T-test for two independent samples, a square (Ka 2), and a Pearson correlation coefficient)) .

Keywords: *The impact of the Quranicsimile - thinking - creative expression - the fourth literary scores.*

Introduction

The researcher feels that there is a clear weakness in the students' expression through his work experience as a teacher at intermediate and secondary schools and this weakness is not represented the existence of a specific course and that there are grammatical and morphological errors in their writings, that there is weakness in their creative expression, as they find it difficult to express or formulate their ideas and implementation of the article or text of the speech for the purpose of meeting in a certain forum. This weakness confirmed many of the literature and previous studies [1] whereas showed that the weakness in expressive performance is due to several factors, including the lack of care of the process of education expression in terms of preparation, and method of teaching, correcting copybooks, being away from the language fluent and colloquial speech with the lack of students to the corners of the expression of vocabulary and ideas in addition to the absence the curriculum and lack of lessons [2,3]. while [4] see problems among the students in the field of expression, the learner does not have the qualifications to be able to express , because of the occurrence of spelling mistakes, or bad line, or the state of the learner psychological may have a certain disability, or stammer tongue and the few languages abilities possessed by the learner make it unable to bind, follow the expression [5]. in addition, many students are afraid to write (written expression) and are working to avoid it, perhaps the reason for the lack of training to write, or not accustomed to them in school or home, until some of them find themselves in the university, He stands in front of the need to write university research requests from him, or scientific reports in the pages, he is not able to accomplish it, moreover, the stress associated with school examinations is another source of this fear. In any case, they will eventually be surprised, when they are surprised by the great amount of writing they need after they join the fields of work, lectures, reports, and correspondence, which negatively affects their progress in their jobs.[6] Based on the above, the

Corresponding Author:
Sattar N. Al-Shaibawee
University of Babylon, College of Basic Education, Iraq

problem of research lies in the answer to the following question: (Does the analysis of the Quranic verses affect the expression and creative thinking of the students of the fourth literary?) The education is the foundation of human reform and its success which is a powerful force that can nourish souls, purify them, and guide them to the worship of the Creator, a complete worship, a force that can develop individuals, sharpen their talents, sharpen their minds and thoughts, train and strengthen their bodies, and at the same time a continuous process that is not determined by a certain period of time The entire life of the individual from cradle to grave. [7] and has been singled out by God Almighty without all human beings, education guidance, orientation, training and care by the community of the human individual to reach the degree of mental perfection, psychological, moral, behavioral and social to be able to exist and live appropriate to him [8].based on the above it be can said that education has an aim to achieve which is to prepare the human to be an active component of society, and to be productive, and able to solve the problems of his life . This can only be done by having a means of communication to do so. The language is one of the strongest obligations on the people, it is a way of thinking, planning identity, it is not a means of speech and expression only, the languages of each nation are the most important elements of its personality, and record their experiences, knowledge, and glories over time. So talk about the issues of language introduction to the rooting of thinking and the liberation of the spirit of creativity, the localization of science and its intelligence [9]. The language is therefore the instrument of intellectual communication inwhich man is able to transfer everything that goes on in his brain of ideas trying to communicate to others in order to develop his ideas, information and increase it to be a productive person. Arabic is the language of the Holy Quran,deriving its vitality and permanence from its texts and principles, and for it to turn the Arabic languageand was accompanied by died languages, as long as the Koran is a miracle of immortal remains in which the research by understanding and enriching the language, developing it and revealing new similar aspects .for the miracles and exploration of the secret of the immortality of the Koran and its greatness. Therefore, we find that any knowledge is built in the mind by mental processes, and that the structure of the mind is working permanently on the reorganization of the cognitive pattern of the learner, whereas (output) is permanently renewed and subject to representation, the relevance is mainly influenced by the learner's positive, effective, integrated experience and its individual characteristics, which make the learning process always an active movement do not stop at a certain moment and make the mind a member renew itself at every moment, its contents and structure change by changing time, space and the elements of the environment surrounding it. Language is a mirror of the human mind. It is a means of thought and understanding. It is also a means of communication and expression, to register the civilization of the nations and preserve its heritage. Before the conversion of man to learn the language lived in the from the time of forgetfulness. Language is then a means and an end in the field of creativity. the interpretation of the Koran is a characteristic of virtue preferred by some commentators, because it is a statement of words to the words of God Miraculous, which I mean in all levels (sound, morphological, grammatical and semantic).Expression is an art of linguistic communication, a mold in which a person pours his thoughts into a sound language, a beautiful picture, and is the purpose of learning the language. It is a means of understanding and learning . It is a tool for conveying thoughts and feelings. And employ them with specific and clear words that carry meanings and sensations for the reader and the reader.Based on the above, there is a need for a scientific study that deals with the analysis of the Qur'anic simile that take into account the role of the student in the educational process rather than relying on the teacher. This study is the impact of analyzing the Quranicsimile in creative expression. It is possible to say that the importance of research comes from the importance of language to man as the first way to manage his life and the means of understanding with others, and the importance of Arabic as the language that was honored to send the Koran.

Limits of human research, spatial and temporal: A sample of fourth scores literary students in the secondary and high school day schools in Diwaniya province, Afak district, for the academic year 2018-2019.

Defined as "an epistemological or cognitive impression, generated by human interaction and influenced by my intention.

Procedural Definition: This is a significant change in the scores of the students of the experimental and control samples in creative expression.

Similes: It is a phrase that contradicts its example, and the meaning of its meaning, or is the statement of

others similar to him in the case of the second in the first, or is the brevity of the word and the injury of meaning and good analogy.

An Expression: Good defined as: the selection, arrangement, development, and expression of ideas in appropriate language or in writing.

A Creative Expression: This is the kind of expression that is meant to show feelings, sensations, emotions, and winged imagination in carefully selected terms characterized by beauty, smoothness, excitement, impact in the reader or listener, and the desire to deal with their subject.

Methodology

Research Methodology: The researcher followed the experimental method, adopting the partial experimental design in the research procedures.

Research community and its sample: The research community included the fourth scores literary students in the high and secondary of day schools in the province of Diwaniyah - Afakdistrict. The researcher chose a random sample of the study and was Afaksecondary school for boys. By two divisions, one of which was randomly chosen to be an experimental group, and the other a control group. Whereas the final research sample is (60) students, and by (30) students of the experimental group, and (30) students to the control group after the exclusion of (5) students failed for the previous year as in the following table as in the following table:

He applied the experiment to the two groups and the same researcher studied the two groups, the experimental according to (analysis of the Quranicsimiles), and the control according to (the normal method).

Table 1. Research community and its samp

No.	Groups	Division	No. of students	No. of failed students	Final students no.
1	Experimental	A	32	2	30
2	Control	B	33	3	30
	Total		65	5	60

The equivalence of the two research groups: The researcher conducted a statistical equivalence between the students of the two groups of research in some variables, including:

The time-period calculated in months: It was found that there is no statistically significant difference at the significance level (0.05). The calculated T value of (0.559) is less than the numerical value of (2) and the degree of freedom (58) Where the chronological age variable, as shown in the following table:

Table 2. Equivalence of the two groups of research in the chronological age calculated in months.

Groups	Sample's size	SMA	Differences	standard deviation	KA values		Freedom's degree	Level of significance
					Calculated	Secluded		
Control	30	187.9	62.06	7.87	0.259	2	58	Not statistically significant at 0.05
Experimental	30	187.5	48.45	6.960				

Educational achievement of parents: The value of Ka2 calculated for parents (0.38), which is less than the value of (Ka2) (7.82), with a degree of freedom (3). (0.05), so that the two groups are equal in the educational achievement variable of parents,as shown in the following table:

Table 3. Academic achievement for parents

Groups	Sample's size	Primary or intermediate	Secondary	Institute	Bachelor and more level	KA values		Freedom's degree	Level of significance
						Calculated	Secluded		
Control	30	9	6	7	8	0.38	7.82	3	Not statistically significant at 0.05
Experimental	30	10	6	8	6				

The calculated value of Ka2 for mothers (0.12): Which is less than the value of the (2) tabular ka (7.82), with a degree of freedom (3). At a level of significance (0.05) thus, the two groups are equal in the educational achievement variable of mothers as shown in the following table:

Table 4. Academic achievement for mothers

Groups	Sample's size	Primary or intermediate	Secondary	Institute	Bachelor and more level	KA values		Freedom's degree	Level of significance
						Calculated	Secluded		
Control	30	5	7	10	8	0.12	7.82	3	Not statistically significant at 0.05
Experimental	30	6	7	9	8				

The scores of students of the two groups of the first course in Arabic language for the fourth literary scores: When using of T-test to find the difference between the scores of the two groups in the first course, the researcher found that the difference is not statistically significant at the level of significance (0.05), the calculated T value of (0.728) is less than the scale value of (2) and the degree of freedom (58). This indicates that the two groups are equal in the first grade in Arabic language, as shown in the following table:

Table 5. The equivalence of the two sets of research in the Arabic language grades of the first course

Groups	Sample's size	SMA	Differences	standard deviation	KA values		Freedom's degree	Level of significance
					Calculated	Secluded		
Control	30	42.73	7.006	7.87	0.728	2	58	Not statistically significant at 0.05
Experimental	30	41.93	7.279	6.960				

Research tool: To achieve the goal of research researcher presented his research tool by identifying a group of experts to select an expressive subject to write students in it was the subject (**Tolerance is a characteristic of believers**)

Statistical Method: The researcher used the following statistical means: (square Kay (Ka 2), T-test (Pearson correlation coefficient).

Results and Discusion

After the researcher applied his research tool to the two groups to write in the expressive subject the researcher collected its papers and corrected them according to the predetermined test for the purpose of correcting the creative expression after he has introduced several simulations for correction a group of experts and specialists in the method of teaching Arabic, in order select one of them through the questionnaire distributed to them. Then the researcher at the end of the research procedures statistical treatments for scores of students obtained from the final test, the results were as follows: When the T test was used to determine the significance of the difference between the average of the two groups of research, there was a significant difference at (0.05) and the degree of freedom (58)

Table 6. Determine the significance of the difference between the average of the two groups of research

Groups	Sample's size	SMA	Differences	Standard Deviation	KA values		Freedom's degree	Level of significance
					Calculated	Secluded		
Control	30	56.2	64.178	8.01	5.129	2	58	Not statistically significant at 0.05
Experimental	30	45.9	58.029	7.617				

Conclusion

In the light of the results and interpretations reached by the researcher, the following can be inferred: The analysis of the Quranic prose is one of the important method in teaching expression to the fourth grade students. Teaching the expression by employing (analysis of the Koranic simile) the teacher is equipped with a wide repertoire of intellectual knowledge that qualifies him to delve into Qur'anic simile and prepare it scientifically as a result of the required knowledge broad on various Quranic interpretations. The analysis of the Quranic verses is suitable for oral expression and the scripture, which creates a variety and makes it good for both types of expression (Functional and creative).

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Babylon, college of Basic Education, Iraq and all experiments were carried out in accordance with approved guidelines.

The Effect of the Multiple-Intelligences strategy on the Iraqi Fourth Preparatory EFL Students' Skills

Estabraq Mubdir Khilkhal[1], Muna M.A. Al-Khateeb[1], Abd Ali NayifHasan[1]

[1]College of Basic Education/University of Babylon, Iraq

Abstract

The main purpose of the current study is to investigate the effect of using a Multiple Intelligences strategy on developing speaking skills of fourth preparatory students in Babil . The experimental research design was used in the study .Tools of the study include techniques and activities based on Multiple Intelligences strategy, checklists of speaking skills, and pre-posttests of speaking skills after assuring their reliability and validity by specialized jury members. The sample of the study was 60 students (30 in the experimental group, and 30 in the control group); students were selected randomly by the researcher. After the application of the experiment, the students were post tested using speaking skills test. Results of the study indicated that Multiple Intelligences strategy had significant effect on improving the students speaking skills.

Keywords: *Multiple-Intelligences, Skills, Iraq.*

Introduction

Multiple Intelligences (hence forth MI) theory opens the door to a wide range of teaching strategies that can be easily implemented in the classroom. In other cases, the theory of MI offers teachers an opportunity to develop innovative teaching strategies that are relatively new to the educational scene[1]. MI theory suggests that all children have different proclivities in the eight intelligences, so any particular strategy is likely to be highly successful with one group of students and less successful with other groups. For example, teachers who use the Songs and music as a pedagogical tool will probably find that musically inclined students respond while nonmusical students remain unmoved. As long as instructors shift their intelligence emphasis from presentation to presentation, there will always be a time during the period or day when a student has his or her own most highly developed intelligence (s) actively involved in learning [10]. In Iraq, according to previous studies such as Basim[12], Al Mudhaffar[6] and Ali et al. [4] shows that most of Iraqi learners find difficulties in using EFL speaking skill and these difficulties may be due to one or more of these elements: constant use of the mother tongue,lack of vocabulary, fear of making errors, improper listening strategies, traditional method of teaching, and the limited time. The human brain is a complex and innovative system for processing information. Information processing begins by entering sensory organs, which turn physical stimuli such as touch, heat, sound waves, or light photons into electrochemical signals.[15] and also that students that have comparative levels of comprehension, could sometimes explain the material in a more suitable way than that of the teacher[1]. Multiple Intelligences Theory (henceforth MIT) is a theory in which Gardner has been countering the traditional view that 'intelligence is a single faculty and that one person is either "smart" or "stupid" across the board'[16]. His pioneering view about intelligence shows that all learners possess at least eight different intelligences working unequally[20]. Although all learners possess these theses, they aren't developed equally[23]. Christison and Kennedy affirm that Gardner also asserted that intelligence is one's ability to apply one or more of the intelligences in ways that are valued by a community or culture which means that a person shouldn't use his intelligences in vicious behavior,

Corresponding Author:
Estabraq Mubdir Khilkhal
College of Basic Education/University of Babylon, Iraq
e-mail: estabraqmk@gmail.com

otherwise it wouldn't be called intelligence[15]. Gardner asserts that strengths 'in most cases' are distributed in a skewed fashion; for instance, a learner may be skilled in acquiring foreign language but unable to find his/her way around an unfamiliar environment or learn a song. Likewise, weakness in learning foreign language does not predict either success or failure in other tasks[21].

Types of Intelligences: Gardner emphasizes that there are multiple ways of learning and thinking as espoused in his theory of multiple intelligences[17].

Verbal-Linguistic Intelligence: Linguistic intelligence is the sensitivity to spoken and written language and the ability to use language to accomplish a specific goal, as well as the ability to learn new languages. Lawyers, writers and poets all possess high level of linguistic intelligence according to Gardner [19].

Visual-Spatial Intelligence: Gardner has described visual-spatial intelligence as the ability to perceive all the elements which are necessary to create a mental image of something and these elements are (form, shape, line, space, colors). These mental images have a strong influence on reasoning [11].

Logical-Mathematical Intelligence: Gardner states that logical-mathematical intelligence as the ability to study problems, and to proceed scientific investigations; he also identifies mathematicians, logicians, and scientists as persons who possess high levels of this intelligence [18].

Interpersonal Intelligence: Armstrong has confirmed that interpersonal intelligence is the ability to notice and make distinctions among other individuals with respect to moods, motivations, intentions, and to use this information in pragmatic ways, such as to persuade, influence, manipulate, mediate, or counsel individuals or groups of individuals toward some purpose. Examples include the union organizer, teacher, therapist, administrator, and political leader [9].

Intrapersonal Intelligence: Self-knowledge and the ability to act adaptively on the basis of that knowledge. This intelligence includes having an accurate picture of oneself (one's strengths and limitations); awareness of inner moods, intentions, motivations, and desires; and the capacity for self-discipline, self-understanding, and self-esteem [10].

Bodily- Kinesthetic Intelligence: "The ability to do things like mime, role plays, marching, interactive spelling, design a product or make a model" refers to bodily intelligence as well as the ability to use the body to express ideas and feelings and to solve problems. And according to Gardner bodily- kinesthetic intelligence refers to the ability to use the body to express oneself (17).

1. **Musical- Rhythmic Intelligence:** This intelligence is expressed as an understanding of and a sensitivity to rhythms, melodies, lyrics, pitch, and timing. Individuals with a strongly developed musical-rhythmic intelligence think with or about music. The intelligence may be expressed through creating songs and melodies, singing, playing instruments, and appreciating music(22).
2. **Naturalist Intelligence:** Most of classroom instruction takes place inside of a school building. For learners who learn best through nature, this arrangement cuts them off from their most valued source of learning. There are two primary solutions to this dilemma. First, more learning needs to take place for these learners outside in natural settings. Second, more of the natural world needs to be brought into the classroom and other areas of the school building, so that naturalistically inclined learners might have greater access to developing their naturalist intelligence while inside of the school building(10).

Speaking Skills: Speaking is an important productive skill because students need to acquire information. In speaking, students learn to use the right pronunciation, stress, and intonation patterns in order to communicate successfully. speaking is defined as the production of auditory signals designed to produce differential verbal responses in a listener [13].Non-verbal communication has effective role in classroom environment and using nonverbal signs, improved confidence of individual listener's ability to understand heard information [3]. Bygate advocates adopting a definition of speaking based on interactional skills which involve making decision about communication [21].Speaking is an interactive process because it requires the involvement of another person unlike listening, reading or writing [24]. The researcher has adopted Brown's standards of speaking skill for her study. Brown standards include: imitative, intensive, responsive, interactive and extensive . Speaking skill is considered as a productive skill that can be directly observed and deliberately assesses the accuracy of listening skills of the listeners and that shows animportant relationship between speaking and listening

skills. Since speaking skills depend on oral production, it is difficult to maintain the accuracy and reliability of this production[13].

Types of Speaking: Basic kinds of speaking are imitative, intensive, responsive, interactive, and extensive. First kind is Imitative which is the ability to parrot back or imitate a word or a sentence. Second one is Intensive is the production of short stretches of oral language designed to demonstrate competence in a narrow band of grammatical, phrasal, or phonological relationships. The third is Responsive that includes interaction and test comprehension but at the somewhat limited level of very short conversations, standard greetings and small talk, simple requests and comments. Fourth one is Interactive; the difference between responsive and interactive speaking is in the length and complexity of the interaction, which may include multiple exchanges or multiple participants. Interaction can take two forms of transactional language, that has the purpose of exchanging specific information, or interpersonal exchanges which have the purpose of maintaining social relationships. Fifth kind is Extensive the oral production tasks include speeches, oral presentations, and story- telling. There are two skills of speaking; those are micro and macro skills. Micro skills means producing the smaller chunks of language such as phonemes, morphemes, words, collocations, and phrasal units while the macro skills imply the speaker's focus on the larger elements: fluency, discourse, function, style, cohesion, nonverbal communication, and strategic options [13].

Methodology

Includes a presentation of the procedures used to achieve the objectives of the study, starting from selecting the population and samples, neutralizing the variables of both samples, designing the instruments and tools of the study, conducting the experiment and analyzing the results.

Experimental Research Design: The experimental design has been adopted by the researchers which best fit the requirements of the study and it contains one independent variable (multiple intelligences strategy) and a dependent variable (students' speaking skills), thus the experimental design was adopted on two equivalent groups one experimental and the other is controlled that are randomly selected by the researcher.

Population and Sampling: The population of the current study is represented by the fourth-grade preparatory school students in the province of Babil for the Academic year (2017-2018) in Al –Afaq secondary school to represent both samples the control and the experimental, which are randomly selected class (A, 30 students) to represent the experimental group and (B, 30 students) to represent the control group.

Samples Equivalence: The researcher conducted a statistical equivalence between the experimental and control groups in some variables that could affect the results of the experiment. Although the researcher chose the two groups randomly, the students of the research sample from similar social and economic status and study in one school. The statistical results demonstrated that the two groups were equivalent in all the aforementioned variables and also in:

1. Students' scores in the pre-test
2. The students' age (In months)
3. Students' scores in English in the mid–year examination
4. Academic Achievement of the Parents

Controlling Extraneous Variables: Extraneous variables are independent variables that have not been controlled.

Therefore, the researcher attempts to control the influence of these variables:

1. History
2. Experimental Morality
3. Maturity
4. Selection Bias
5. Instrumentation

Teaching Material: The teaching material that was used in conducting the experiment was represented according to the MI strategy and was taught during the second course of the academic year (2018-2019) . In which the researcher set a number of activities to be learned by the experimental group, and for the lesson plans the researcher prepared a total of (28)lesson plans for each group. The experiment lasts for 9 months and the researcher teaches the two groups herself during that period of time.

Research Instrument:

Teachers' questionnaire: A questionnaire of 35 questions were designed by the researcher and were answered by 88 secondary teachers which prove according to the experienced teachers that:

- Fourth preparatory students face difficulties in speaking,
- Most teachers use traditional method of teaching, and
- MI strategy is interesting, valuable, and effective.

Pilot study testing: The researcher chose a school that is located near the main school on which the experiment was conducted, (66) students from Al-Kifah secondary school were tested by the researcher and the results of the students proved the test validity.

The pre-Test:

- The purpose of the test: the test was designed to measure the students' speaking skills.
- Determining test items: the test items were designed by the researcher to be 10 items and prepared a scoring scheme for the test.
- Test scoring: Brown's scoring scheme was adopted and adapted by the researcher.
- Test validity: the test was validated by jury members of language teaching specialists which gave some recommendations that the researcher took into her consideration. The test was also validated by testing it to a pilot study.

The test validity: The test is designed according to the general objectives in the "English for Iraq" student's book regarding the skill of speaking and had been sent to a specialized jury members who approved its validity.

The Test Reliability: Reliability of a test is defined as how the scores of the test reflects the true ability level of the students being tested and it can also be defined as the degree to which a measurement instrument gives the same results each time that it is used. To verify the reliability of the test, the researcher used "Cronbach Alpha" so when applying this method, the value of the correlation coefficients (0.935) which is calculated as a high correlation coefficients.

Results and Discusion

The students of the experimental group who were taught according to the MI strategy were superior to the students of the control group, who studied according to the traditional method in the post-test, thus rejecting the first null hypothesis and accepting the alternative hypothesis: (There is a statistically significant difference at the level of (0.05).

Table 1. The students of the experimental group who were taught according to the MI strategy

The mean results of both groups					
	Group	**N**	**Mean**	**Std. Deviation**	**Std. Error Mean**
Pretest	Control	30	62.23	16.65	3.04
	Experimental	30	62.47	16.88	3.082
Posttest	Control	30	63.47	16.081	2.936
	Experimental	30	72.07	14.527	2.652

Conclusion

Based on the results of the study it can be concluded that using multiple intelligences strategy is an effective way to develop the speaking skills through focusing on individual differences among students according to their multiple intelligences . It is also concluded that adopting the new trends in teaching like the MI strategy which focuses on the changing role of the teacher from being a teacher to a facilitator enhances students' achievement.

Investigation of Some Corticosteroids in Human Biological Fluid Using Thin Layer Chromatographic

Zena Sattam Hamad

Department of Pharmacology and Toxicology, College of Pharmacy, University of Mosul, Iraq

Abstract

Corticosteroids are a type of steroid hormones, which are generated in the adrenal cortex, also there are the synthetic analogues of these hormones. Steroids play an important role in many biological actions with numerous therapeutic applications. Corticosteroids side effects associated with unpredictable risk of illness as a result of corticosteroids abused. The study was conducted in Mosul city from 15th of January 2018 to 15th of December 2018 in private clinics. Fifty outpatientswere included in this study, they were divided into five groups, and each group includes 10 patients was used one of the five types of corticosteroids, including hydrocortisone, betamethasone, dexamethasone, prednisolone and triamcinolone. Samples of 1ml collected from the patients, prepared after alkaline chloroform extraction then spotted onto the thin layer plate.Rf value were (0.72, 0.7, 0.67, 0.69, 0.7) of hydrocortisone, betamethasone, dexamethasone, prednisolone, triamcinolone respectively, some of them had the same Rf values due to the similar structure. Endogenous substances from blood samples were not found to have interferences in results with this method.

Keywords: *Thin layer chromatography (TLC), Steroids, Biological fluid, Abuse Drug.*

Introduction

Corticosteroids are a type of steroid hormones. Those hormones are generated in the adrenal cortex, also the synthetic analogues of these hormones [1]. Steroids play an important role in many biological actions with numerous therapeutic applications. It regulates digestive processes, controlling metabolism, control the development and functioning of the sexual organs and water-mineral balance. Steroid drugs are used as potassium-sparing diuretic or contraceptive drugs or anti-inflammatory, anti-asthmatic drugs and synthetic hormones[2]. Corticosteroids side effects, including poor control of the adrenal axis, diabetes mellitus, osteoporosis and opportunistic infection[3]. The possibility of Cushing's syndrome, asthma, herpes keratitis and pneumonia can be associated with unpredictable risk of illness as a result of corticosteroids abused[1]. This is because of; as a result of interest effect the drugs produce, are abused for this effect than the goal they are needed for [4]. Many techniques like Gas chromatography-mass spectrometry (GC-MS), High-performance liquid chromatography (HPLC) with ultraviolet-visible detection (UV–VIS)[5,6], High-performance liquid chromatography-mass spectrometry (HPLC-MS)[7], for dependable and good quality analysis have been used. However, high cost, time-consuming, and complication have been considered as a drawback of all the method mentioned above[8,9]. Therefore, this study choses a fast, highly-selective and low-cost screening technique (TLC). For investigation, separation and analysis of compounds, TLC is the most efficient and popular technique has been used. Worldwidely, approximately 60% of the performed analyses are based on TLC. Therefore, knowledge of the principles and functioning of TLC is a critical[10]. There are large numbers of research article published for TLC, which confirms that TLC is hugely used for the experimental purpose in pharmaceutical, drug, and cosmetology analysis of natural and synthetic steroids[11]. The separation of two

Corresponding Author:
Zena Sattam Hamad
Department of Pharmacology and Toxicology, College of Pharmacy, University of Mosul, Iraq

or more compounds by moving between two phases first is stationary and other is a mobile phase is the exact definition of chromatography [12,13]. Modern approaches in thin-layer chromatography enable analysts to separate and determine steroids in complex mixtures, including various environmental samples such as biological fluids, plants and pharmaceutical formulation [2]. The aim of this study is to investigate the presence of some abused corticosteroids in a human biological fluid.

Materials And Method

The study was approved by the Medical Research and Ethics Committee of the Department of Pharmacology and Toxicology, College of Pharmacy, University of Mosul (Iraq). Before the beginning of the study, all participants were given written informed consent.

Drugs and Patients: Fifty outpatients were included in this study. They were collected from private clinics, they were divided into five groups, and each group includes 10 patients who used one of the five types of corticosteroids, including hydrocortisone, betamethasone, dexamethasone, prednisolone, and triamcinolone. Each of these corticosteroids was used by the patients for a period not less than 3 months.

Solvents and chemicals: Ethanol as an organic solvent was used to prepare standard samples (ethanol absolute, analytical grade (Scharlau/UN).

Preparation of 2N ofammonium hydroxide (NH_4OH): 2N of NH_4OH/100ml was prepared by dissolving 31.25ml of concentrated NH_4OH of 6.4 N in a 100ml volumetric flask and then the volume was aliquot to 100ml by distal water.

Preparation ofpotassium permanganate 1% location reagent: One g of potassium permanganate in sufficient water to produce 100ml.

Standard and Sample preparation:

Standard solution of each drug was prepared by dissolving appropriate weighed amount of authentic drug of the five mentioned corticosteroids obtained from SDI (Samara Drug Industry) in ethanol, and then spotted on thin layer plates.

Samples were collected about 1ml from each patient. After alkaline chloroform extraction ammonium hydroxide (0.25ml, 2N) added to each sample in a glass separatory funnel then 5ml of chloroform added. The contents were then vortexed for 30 seconds. Evaporated to dryness under a stream of air, the 4ml organic layer of chloroform then 50µl chloroform re-dissolved the residue and approximately 40µl spotted on thin layer plates.

Mobile Phase: Prepared by mixing (Ammonia solution extra pure (Scharlau/UN): Methanol extra pure (Merck/Germany) in (1.5:100).

Chromatography: Plates of thin layer plastic sheets of non-fluorescent type (silicagele-60 5×10 cm, Merck, Kieselgel 60/Germany) were used to perform Chromatography. Developed in a tank containing the mobile phase (strong ammonia solution : methanol (1.5:100)). Then plates were sprayed by potassium permanganate solution as a location reagent after they dried.

The Rate of flow (Rf) was calculated as follows:

Rf = Distance of the substance area from the sample origin (mm)

Migration distance of solvent front (mm)

From the starting line to the center of the substance spots the distance was calculated. Spots derived from the standard compounds must be similar to spots of the sample solution in their Rf values, shape, and color [14].

Results and Discusion

No interferences in results due to endogenous substances from blood samples were found with the method described above. Table (1) shows the rate of flow (RF value) and the spots color.These parameters (RF value and the spots color) are important in diagnosing the unknown spots which may be revealed from any biological fluid sample. Consumption of drug of abuse is an insult to modern world; however, the drug is either legally medicinal product or highly risk drug. The age group of 14 to 35 years old is the special ages affected in the society in addition to all age groups. One of the great problems in the society was the abused drugs and their consequences [15,16]. Due to their significant results in person, family and public level as well as in the economy [17]. Therefore, application of thin-layer chromatography TLC in pharmacy is very important. Their researches published in the field of pharmacy steadily rise. It results from the fact that interest in TLC has increased with improvements in TLC instrumentation and method [18]. On TLC plate; the Rf value were (0.72, 0.7, 0.67, 0.69,

0.7) of (hydrocortisone, betamethasone, dexamethasone, prednisolone, triamcinolone) respectively, some of them had the same Rf values, like betamethasone and Triamcinolone due to their similar structure. The drug of abuse can be investigated from different biological fluids, the choice of the sample depend on the purpose of the analysis [4], and the content of biological sample is very complex include endogenous and exogenous substances in addition to the drug wanted to be investigated, therefore, it is very important to be preceded with specific isolation procedures [19]. These method used when the investigated drug must be extracted to facilitate their isolation from aqueous solutions in organic solvents and often it needs several solvents and operations of extraction, purification and separation [20,21]. Investigation and identification of abused drugs in biological fluids gives to the specialists a key for the diagnosis of these drugs.

Table 1. The rate of flow (R_f value) and the spots color.

Drugs	Rfvalue		Spot color
	Authentic standard	Blood extract	
Hydrocortisone	0.72	0.72	Bright yellow
Betamethasone	0.7	0.7	Bright yellow
Dexamethasone	0.67	0.67	Bright yellow
Prednisolone	0.69	0.69	Yellow
Triamcinolone	0.7	0.7	Yellow

Conclusion

The choice of the separation method (chromatographic method) depends on physicochemical properties of the compound being separated, equipment available and sensitivity required for analysis. The time needed and the cost is also important. For these reasons; an inexpensive, fast, highly selective screening technique TLC used for a quick investigation of some abused corticosteroids in human biological fluid. TLC greatly contributed to the analysis of different drugs in comparison with other analytical techniques including Gas-chromatography and High-performance liquid chromatography because of their running cost, complication and time-consuming.

Financial Disclosure: There is no financial disclosure.

Abstract

In Indonesia, waste reduction program done at the community level, through 3R-based waste management (TPS3R) unit and waste bank, has a national target of 30% in the period of 2017-2025 under Presidential Regulation No.97 Year 2017. An effective waste reduction effort can be measured by two main indicators, first is the percentage of recycled waste, and other indicator related to legal, financial, service coverage, and community participation. This study aims to explore the effectiveness of solid waste reduction through TPS3R and waste bank services in three cities, Depok, Bogor, and South Tangerang. A cross-sectional study was done collecting data from multiple sources namely municipality's record, regional policy, and official government news. The results showed that the percentage of effectiveness of waste reduction to landfill in three cities has not reached the national target, which was still below 5%. The highest effectiveness of waste reduction by TPS3R and waste bank was achieved by Depok which has 3R related local regulation. The city with largest budgeting allocation for solid waste management was Depok. YetBogor with a budget allocation of 2.2% could achieve the value of half effectiveness of Depok. South Tangerang with the best coverage of TPS3R unit services has the lowest effectiveness value despite its high Human Development Index (HDI) value. Likewise, TPS3R services had higher effectiveness for reducing waste than the waste bank.

Keywords: *Solid waste management, solid waste reduction, 3R concept, waste bank, effectiveness.*

Introduction

Solid waste generation in developing countries is increasing rapidly due to the increase of population growth, economy, urbanization, and the rising living standards in society[1]. This situation creates a gap between per capita consumption of natural resources and solid waste production with the ability of ecosystems to supply natural resources and absorb waste contrarily[2]. Currently, solid waste is a serious and urgent problem for most cities in developing countries[3]. In Indonesia, most people still throw solid waste to the rivers, ditches, gardens, vacant land, burned, or buried.Only 27.9% of households have access to solid waste transportation services by waste collection staffs[4].In addition, 57% of landfill in Indonesia still using the open dumping system in 2015[5]. However, the environmental impacts of open dumping will take a long time to disappear and potentially harmful to public health[6].

Considerably, Indonesia issued a LawNo. 18 of 2008 on Solid Waste Management containing about Reduce, Reuse, Recycle (3R) concept. Two different ministries then regulate the waste reduction management at the community level. First is 3R-based waste management unit, which is called TPS3R (*Tempat Pengolahan Sampah berbasis* 3R –Reduce, Reuse and Recycle), except in Depok City is named as UPS (*Unit Pengolahan Sampah*), under the Ministry of Public Works and Public

e-mail: sabrin1@ui.ac.id

Housing Decree No. 03/PRT/M/2013. Second is waste bank, regulated by the Ministry of Environment and Forestry issued Decree No.13/2012, as the community initiative waste management unit. TPS3R and waste bank have different procedure in managing the solid waste at the community level.

The waste collection staff in TPS3R will collect and transport household solid waste through door to door services. Solid waste from the community will or will not be sorted at each household before being transported—with or without waste separation—to TPS3R unit site whereas then the worker will sort the solid waste into biodegradable, non-biodegradable, and residual waste. The biodegradable solid waste will be processed into compost, non-biodegradable solid waste with economic value will be sold to private sector, and residual waste will be sent to the landfill. Meanwhile in waste bank, waste bank member will sell the non-biodegradable solid waste which have economic value then can get some money[7].

In 2016, the number of TPS3R has reached 981 locations throughout various cities in Indonesia, which 10% of it has been running well[21]. Waste bank, until 2018, is known to reached 5,244 units with a total of 174,904 customers spread across 218 districts/cities and the contribution of waste bank in solid waste reduction effort has reached 1.7%[8].

In 2015, Wilson et al. (2015) wrote an analytical framework for city's solid waste management system quite comprehensive, capturing two overlapping triangles. First is a hard factor, that is physical components comprising of collection, recycling and disposal. Second, as a soft component, it is a governance aspects, consisting of inclusively, financial sustainability, and proactive policies. Referring to those indicators, this study aims to describe the percentage of solid waste managed in TPS3R and waste bank, in addition to explore the factors related to the effectiveness of urban solid waste management.

Method

This study used cross-sectional design in three cities of West Java and Banten Provinces, namely Depok, Bogor, and South Tangerang, in 2018. The study population are all TPS3R in 3 cities with total 120 units which counted fromDepok (45 units), Bogor (26units), and South Tangerang (49 units), and all waste banks in 3 cities amounted to 608 units; Depok (428 units), Bogor (24 units), and South Tangerang(156 units).

A multiple data sources are used. The records were drawn from Environment and Sanitation Office, Central Bureau of Statistics, TPS3R unit, and waste bank. The list of TPS3R and waste banks for this study are provided by the City's Environment and Sanitation Office. The source of data on municipal solid waste generation, amount of budget, budgeting allocation, and number of an urban village and neighborhood area, are taken from online publication.

The reduction of waste generation to the landfill is measured by the effectiveness formula that has been developed[10]. Here are the measurements of the effectiveness of waste reduction:

$$Effectiveness = \frac{Wastemanagedin TPS3R + Wastemanagedbywastebank}{Wastegenerationofanentirepopulationinacertainperiod} \times 100\%$$

Research permit was obtained from the Municipality Local Government in three cities.

Results

TPS3R in Bogor and South Tangerang were managed by the local community group, while Depok were managed by the local government. The value of effectiveness of waste reduction by TPS3R unit and waste bank in three cities was still very low and has not fulfilled the national target (30%) with the effectiveness of TPS3R unit and waste bank in Depok (4%), Bogor (2.06%), and South Tangerang (1.48%). The percentage of solid waste reduction in TPS3R was higher compared to waste bank. For example, in Depok, solid waste reduction in TPS3R is 2.9% and solid waste reduction by waste bank is 0.68%, as well as in Bogor and South Tangerang (Table 1).

Table 1. Effectiveness Percentage of Waste Reduction through TPS3R and Waste Bank in Depok, Bogor and South Tangerang

Variable		Depok		Bogor			South Tangerang		
		TPS3R	Waste Bank		TPS3R	Waste Bank		TPS3R	Waste Bank
Number (and % of Active) TPS3R and Waste Bank		45 (66.7%)	428 (100%)		26 (92.3%)	75(33%)		49(71.4%)	156 (100%)
	Total solid waste in city	Processed by TPS3R**	Processed by Waste Bank	Total solid waste in city	Processed by TPS3R*	Processed by Waste Bank	Total solid waste in city	Processed by TPS3R*	Processed by Waste Bank
Municipal Solid Waste (kg/day)	1,321,000	38,663	9,100.6	648,000	13,079	263	880,000	12,150	865.5
Effectiveness of waste reduction (%/day)	4%	2.9%	0.68%	2.06%	2.01%	0.04%	1.48%	1.52%	0.108%

*TPS3R process organic and inorganic waste, **TPS3R only process organic waste

Although the three cities already have local regulations related to solid waste management, local regulations about 3R related to solid waste management were only available in Depok and South Tangerang.Regarding budget variable related to cleanliness and solid waste management in each city, Depok got the highest percentage of the budget compared to the other two cities (Table 2).

Table 2. Waste Management Governance Aspectsin Depok, Bogor and South Tangerang

	City		
	Depok	Bogor	South Tangerang
Governance Aspects			
Legal Dimension			
Availability of local/district/ city/regency regulation on waste management related to 3R	There is a 3R related waste management regulation in Local Regulation of DepokNo. 5 Year 2014 about Waste Management	There is a waste Management regulation but not 3R related waste management in Local Regulation of Bogor No. 9 Year 2012 about Waste Management	There is a 3R related waste management regulation in Local Regulation of South Tangerang No. 3 Year 2013 about Waste Management
Local regulation related to 3R waste management	There is mentioned in Local Regulation of Depok No.5 Year 2014 Article 9	Not yet mentioned about 3R	Not yet mentioned about 3R
Finance			
Amount of budget at Environment and Sanitation Office	Rp 346,8 billion or 12.9% from a total of Regional Budget	Rp 43,9 billion or 1.8% from a total of Regional Budget	Rp 96 billion or 4.08% from a total of Regional Budget
Community Aspect			
Human Development Index score	79.83	75.16	80.84

Not all TPS3R units were active in conducting 3R based waste processing activities. The most active TPS3R unit was in Bogor (92%) and the most inactive TPS3R unit was in Depok (33%).

Discussion

The effectiveness of TPS3Rand waste bank in three cities was still low, while in European Countries, the average percentage of waste reduction through recycling, composting, and bio-waste digestion has been reported 33% in 2014. Some developed countries like Germany, Austria, Netherland, Switzerland, Belgium, and Denmark has reached minimum percentage of 50% for household solid waste recycling[11]. Based on national standard in Indonesia, the solid waste reduction target of 30% had not been reached yet.

TPS3R in Depok only recorded the amount of solid waste, which can easily decay so the solid waste reduction became low. Meanwhile, the amount of solid waste that cannot easily decay and has economic value was not recorded either in TPS3R or in local government in Depok. The local government should improve reporting and recording data in TPS3R, waste bank, and the Environment and Hygiene Office.

It is interesting to note that the effectiveness of the solid waste management in these three cities may be underreported because this study does not include the solid waste recycling activities undertaken by the scavengers. Based on previous study, total solid waste taken by scavengers in Indonesia can reached 10%[12]. The local government should count the numbers of scavengers in the area actively, and record the number of non-biodegradable solid waste from them.

The effectiveness of solid waste reduction by TPS3R in three cities had higher percentage than waste bank. In general, TPS3R received all types of solid waste, while waste bank only took non-biodegradable solid waste having economic value. Meanwhile in TPS3R, household solid waste from the community was picked by waste collection staff of TPS3R. Refer to the previous study,solid waste collection coverage is included as an indicator of solid waste management performance[13].In waste bank, the member deliver their waste individually and voluntarily to waste bank. This condition requires a very high voluntary level;hence, there is no guarantee that household solid waste can be transported properly to the waste bank. The local government should encourage every household to sort solid waste. The household solid waste which has been sorted will be transported in a separate method by the waste collection staff.

The low number of solid waste reduction related with legal, institutional, and financial aspects. On legal aspect, local regulations greatly affect the community's behavior in terms of handling solid waste. Most local governments do not have local regulation of solid waste management as a derivative of Law of Republic of Indonesia No. 18 of 2008. The value of effectiveness achieved by Depok can be due to the regulations which clearly mention the obligation to sort waste in the community. Some results of previous studies based on household perceptions indicate that household participation in sorting/recycling solid waste will increase if households trust the government. Steps needed to increase trust are issuing laws, establishing detailed regulations, and enforcement of solid waste disposal/ recycling behavior[14]. Thus, each local government should have 3R solid waste management rules.

In the financial aspect, the allocation of budget for cleanliness and solid waste management in Depok was higher compared to other cities in Indonesia. The average budget allocation of solid waste management in cities around the world was between 3%-15%[15]. However, the average size of solid waste management budget in all cities in Indonesia was 2%. In Bandung, the budget allocated for Environment and Sanitation Office was 2.3% and Surabaya was 5.5% in 2012. Due to TPS3R in Depok were fully funded by the local government, the householdthen do not have to pay their service. While in Bogor, it onlyhad budget allocation for maintenance and salary of employees as much as 4 people ini every TPS3R. The employeeswere paid 65,000 Rupiah (around 4.44 USD) plus extra dairy food or snacks per day. The community contributed to fund the other operational cost of TPS3R through waste contribution payment. The household served by TPS3R had to pay their service between 3,000 until 30,000 rupiah or 0.25 until 2 USD depending on the consensus and agreement of each community.In the meantime, South Tangerang did not allocate budget for TPS3R, all the operational cost in TPS3Rwere fully funded by community.

The solid waste reduction in the city also related with the availability of the community to access TPS3R and waste bank. In this study, all of the waste banks were active. The availability of good access will encourage community behavior in managing solid waste. Access can be seen from the number of places of waste processing (availability) and distance traveled (accessibility)[16]. Based on previous study, the closer the distance to waste recycling sites, the greater the household participation in sorting and recycling waste[17]. In line with other studies which stating the households are unwilling to bring recycled waste to waste banks or recycling centers because the distances are far from home[18]. The optimal distance from the household to recycling center was 75 meters[17].

Although there is no regulation stated about the scope of waste bank, yet in practice waste bank generally build in neighborhood area level. While TPS3R has been regulated to serve more than 400 households, which larger than a neighborhood area village[19]. Thus, in this study we assumed that TPS3R served the urban village area and the waste bank served the neighborhood area.

It is likely that the availability of TPS3R and waste bank unit in three cities have not yet cover the need of the entire community in cities.

The availability of TPS3R unit can be attributed to the lack of land that can serve as TPS3R. One of the issues of national waste development is the provision on solid waste management infrastructure and facilities not yet included in the Spatial Detail Plan of local government. The determination of the landfill site is already listed in the Spatial Plan, but for TPS3R has not been listed because of the central and regional government has no integration in the perception of the importance of the national strategic for spatial planning[20]. Based on this, TPS3R location is needed to be required in the Spatial Detail Plan.

On the effectiveness of TPS3R unit managed by the local community group, Bogor showed better results compared to South Tangerang. Community access to TPS3R unit was best achieved by South Tangerang with almost 100%, but the effectiveness value achieved was not too high compared to the large access. This can be attributed to the level of community participation. The level of community participation in this study can be approximated by the Human Development Index (HDI). HDI in South Tangerang is the highest, but the participation rate is still low. The waste banks management is done by local communities with high community participation rate. However, in South Tangerang, waste bank has the lowest availability of communityaccess although the HDI was the highest among three cities[9]. This can be studies furthermore in regard to increase number of the waste bank availability.

The presence of active and non-active TPS3R in each city indicated that the related institutional aspects of maintenance have not been able to perform optimally. Inactive TPS3R may be due to unclear land ownership, destroyed buildings, difficult access to TPS3R, and functional shifting. The other thing related to the lack of maintenance in TPS3R is due to obstacles in operational and maintenance costs. The source of funds used for the implementation of TPS3R comes from the government, contributions from the public, and private[19].

Conclusions

The effectiveness of waste reduction to landfill through TPS3R and waste bank is still very low (less than 5%) and has not met the national target of waste reduction by 30%. The percentage of effectiveness achieved by TPS3R unit is higher than waste bank. The budget allocation managed by Environment and Sanitation Office is highest in Depok, but Bogor with a budget of only 2.2% can achieve half of the effectiveness of Depok. To improve TPS3Rand waste bankperformances, it is called for regular training to the personnel or the community, and monitoringto those units done by the city.

Evaluation of Workers' Protection from Occupational Disease as a Part of the Occupational Safety and Health Program in the Ministry of Manpower Republic of Indonesia

Sudi Astono[1], Maruf Akbar[2], Moch. Asmawi[2]

[1]Postgraduate on Human Resource Management, Universitas Negeri Jakarta-Indonesia,
[2]Human Resource Management, Universitas Negeri Jakarta-Indonesia

Abstract

Occupational diseases (OD) are a critical matter in occupational safety and health (OSH) programs. Until 2017 in Indonesia, there was very few data of OD cases (25/0.02%) when compared to data of occupational accidents (OA) cases (106,889/99.98%) annually. This study aims to garner support for an increase in workers' protection measures regarding OD as a part of the OSH program and to focus attention on the participation of stakeholders in delivering workers' OD protection on a par with OA protection. This qualitative study data were collected and analyzedwith the matrix of the Stake Countenance Evaluation Model (in congruency and contingency). The results of this study showed there are five main factors contributing to workers' lack of protection from OD, as compared to OA cases: 1) lack of stakeholder understanding, competency, commitment, and participation; 2) inadequate planning and budgeting, policies and regulations; 3) lack of law enforcement of the labor laws; 4) poor distribution and function of OSH facility services; and 5) poor OD case handling, data collection, and management.

Keywords: *Occupational accident, occupational disease, workers' protection, occupational safety, and health.*

Introduction

Workers in the socio-economically active population face the risk of not only general illness, but also specific illnesses classified as occupational diseases (OD), in addition to occupational accidents and injuries (OA/OI)[1,2]. They are likely to have limited income and resources, and without proper social protection[3-6]. The employer must protect employees from job–related risks through the Total Worker Health (TWH) program, an integration of OSH protection and health promotion to confront OI and OD, and to advance health and well-being[7-14]. Less attention has been given to the problem of OD, thus only a small number of workers have access to occupational health (OH) services[15,16].

OD is a critical problem, important aspect, and one of the main objectives of the OSH program, together with protecting workers from OA[17,18]. From the perspective of human resource management (HRM), OSH programs are part of the efforts to manage workers as human capital assets for a company or an organization, and as a fundamental concern for a productive, happy and healthy workforce, which is essential to economic development[16,19,20-22], and the minimisation of loss and other negative effects of OD and OA/OI[1,7,8]. OD and OA are increasing: cases of illness and injury causing fatalities from 2.33 million in 2014 to2.78 million people in2017. The OD mortality was 2.4 million (86.3%) of the total estimated fatalities; for OA it was 0.38 million (13.7%) annually[4,23-25].This situation is referred to as the silent epidemic of OD, in which hidden OD cases

do not receive health services according to standards and do not have the right to workers' compensation in accordance with the regulations[26,27], causing global economic losses on average of 3.94% to 4% of a country's Gross Domestic Product (GDP) annually[4,28-30].

According to national regulations, workers with OD, just as with OA/OI, are entitled to workers' compensation benefits[10,31-35], but OD cases diagnosed and receiving workers' compensation in Indonesia until 2017 in average only 25 cases (0,02%) while for occupational accidents (OA) was 106,889 cases (99,98%) annualy. That is a very big gap when compared with ILO estimates (2008) that in the world, there are 160 million OD cases (37,2%) and OA cases of 270 million (62,8%) annually. This reflects that implementation of OSH programs still lack attention in protecting workers from OD, than protections for OA/OI. This research aims to evaluate and make recommendations on an increase in workers' protection from OD as an integral part of the OSH program, so that OD cases will receive their workers' compensation benefits according to national regulations. The recommendation is needed to promote attention and participation of stakeholders, especially policymakers, OSH officers, labour inspectors, and OH doctors, in the delivery of workers' protection from OD as well as from OA cases.

Method

The study used qualitative approachin accordance with evaluation research using the Stake Countenance Evaluation model. This evaluation model consists of three main components of evaluation: antecedents, transactions, and outcomes.

The data was grouping to three evaluation criteria consist antecedents, transactions, and outcomes. The Antecedents (input) consists: human resources, facilities, budget, strategic planning, and supporting of national policy and regulation. The transaction (processes) consist: activity according to the planning (capacity building of stakeholder, labour inspection and low enforcement), monitoring, performance appraisal, and program evaluation of OSH program/activities. The outcomes consist: the results of the OSH program related to OD protection and its follow up.

The data were obtained from various documents of policy and regulation programs, as well as the results of activities and programsin the form of meeting reports or summaries in the Indonesian Ministry of Manpower (MOM) office, for the period 2015–2017. Other data was obtained from interviews, discussions, observations, and attending activities or meetings related to the OSH program implemented by the MOM and other stakeholders, especially company doctors who are members of the Indonesia Medical Association of Occupational Health (IMAOH), and activities carried out in cooperation between the two bodies. Interviews were conducted with 30 respondentsconsist: policy makers and programs at the MOM, OSH labour inspectors, OSH analyst, and occupational health doctors. Observations were conducted in various OH and OSH–related activities, such as seminars, conferences, workshops, focus group discussions, social events, and discussions on drafting regulations, OH and OSH personnel training (OH doctors and OSH officers). Observations also took place at informal discussions or forums followed by OH professionals, including government officials, experts, academics, and practitioners.

The data were recorded and analysed using the matrix of the Stake Countenance Evaluation Model. Analysis to the component of antecedent, transactions and outcomes with congruency and contingency approach to take conclusion (judgement).

Results

It was found considerable relevant information and documents regarding the implementation of OD protection efforts for workers through the OSH program conducted by the MOM. There were only a few OSH programs that have been implemented to draw attention to the OD situation. It is in line with data from the Social Security Administration Agency (BPJS), until 2017, reported the number of OD cases that were given worker's compensation (JKK) in Indonesia in average at only 25 (0.02%), compared to OI cases that reached 106,889(99.98%)annually.

Countenance Stake Analysis Matrix revealed five main factors explaining the lack of workers' protection from the consequences of OD as contrasted with OA cases**:** 1) lack of stakeholder understanding, competency, commitment and participation; 2) inadequate planning, budgeting, policies and regulations; 3) lack of labour laws enforcement; 4) poor distribution and function of OSH facility services; and 5) poor OD case handling, data collection and management.

According to the findings of this study, these recommendations can be proposed to increase OD protection as an important part of the OSH program. This recommendation ordered following priorities from first to the last:

1. Increase the understanding, competency, commitment, and participation in OD protection on the part of key stakeholders: OSH analyst, OSH labour inspectors, and OH doctors;
2. Upgrade a reformulation of OSH policy and regulations relating to OD protection;
3. Insert OD protection aspects appropriately in planning and budgeting documents;
4. Increase distribution and function of OSH facility services: occupational health laboratory, occupational health services, and work environment laboratory;
5. Strengthen labour law enforcement by implementing OD norms and regulations;
6. Improve OD case handling, data collection and management appropriately.

Discussion

The OD issue is an important aspect of the OSH program in Indonesia. It has strategic value, because it governs the protection of productive workers in the economically active population, which accounts for 121 million people (47.4%), or almost half of the total population of 255.2 million people (BPS, 2016). On the other hand, Indonesia's population growth has led to a demographic issue, because it is dominated by young people, so the proportion of workers will be even greater in the future. Young workers (24-28 years old), are employed in all types of enterprisesformal, informal, small and medium enterprisesand in all sectors, so they are much more vulnerable to experiencing workplace harm.

Based on this study, there is the potential that the OD casesare not being detected, but workers experiencing work–related illness go to PH services and may experience several implications, among them, misdiagnosis of illnesses by doctors who do are not familiar with occupational diseases, incorrect treatment, and, of course, having no worker compensation. This last condition also indicates that the implementation of the OSH program has not been carried out comprehensively, because most of the programs are dominated by the OA aspects, and only a few pay attention to OD issues. Thus, a comprehensive evaluation is needed to determine the factors that hinder efforts to protect workers against the consequences of OD, in order to improve the quality of workers' protection through the OSH program.

Until 2017, the number of OD cases reported, handled, and provided workers' compensation in average was only0.02%, in contrast to OI cases numbering up to 99.98% annually. If this condition is compared to the ILO data survey, the proportion of OD cases is greater than 50% of the number of OI cases reported. In light of the ILO report's statistics, it can be surmised that cases of OD areindeed a silent epidemic[26]. Hence, it can be assumed that the number of hidden OD cases in Indonesia is substantial. These hidden OD cases are thought not to have been treated appropriately, and those who suffered them did not receive any workers'compensation[26,36].

The implementation of the MOM's OSH program has not been comprehensive, because it is still dominated by OI aspects and pays little attention to OD aspects. Based on these results, the OD protection program for workers must be improved, along with the protection of workers from OI, through comprehensive implementation of the OSH program[37].

Prevention of OD is very important to create awareness in the general public of the severity of this silent epidemic of occupational diseases, which is estimated to cause 86% of the deaths at work[26]. On the other hand, according to the TWH program, the OSH program should also be integrated with PH programs at work in order to protect workers from OD and OI, and to enhance the workers' health and well-being[28,38]. Giving workers protection from the consequences of OD is equally as important as giving attention to OSH comprehensive programs, and providingtheir benefitsmore expansively[39-42].

Conclusions

Although the OSH program is basically targeted towards protecting workers from bothOI/OA and OD, in terms of prevention, handling and providing workers' compensation, the OSH program by the MOM still focuses lack of attention on OD protection and prevention programs. Losses due to OD are most significant for the workers themselves, but they also have an impact on the employers and subsequently become a loss for the country. MOM must exert greater efforts urgently in increasing workers' protection from OD, in order to increase the quality of life of the workers as strategic human capital and to prevent or at least to minimise the losses for employers as well as the country.

Abstract

A prospective comparative study on 521 pregnant women (≥32weeks) with iron deficiency anemia (IDA) between July, 2019 and September, 2019 at Kasralainy hospital in Egypt, to evaluate adaptation of the fetus to withstand maternal IDA by Doppler parameters, to know the cut-offs of maternal hemoglobin at which complications exist, and to evaluate the effect of treatment (oral iron, parenteral iron or blood transfusion) on fetal hemodynamics and neonatal outcome by birth weight and APGAR score at delivery.

Groups subjected to Doppler examination of umbilical artery, middle cerebral artery (MCA) and renal artery on admission, ten days after treatment by oral iron for mild anemia parenteral iron for moderate anemia, or blood transfusion for severe anemia, again at delivery. Results showed a significant difference regarding Doppler parameters of umbilical artery, renal artery and MCA on admission, ten days after treatment and at delivery explained by vasodilatation of the MCA (brain sparing effect) in moderate and severe anemia, a higher percentage of IUGR in group (C). Treatment corrected Doppler changes and decreased fetal and neonatal complications attributed to anemia especially in severe anemia.

Clinical Trials.gov ID registration: NCT04016922

Keywords: *Maternal anemia, Doppler, IUGR, Neonatal outcome.*

Introduction

Hemoglobin concentration diagnoses and determines severity of anemia, it's screened using WHO-defined cutoffs at lower value for pregnant women than non-pregnant (11 g/dl versus 12 g/dl). Severity determined using cutoff of hemoglobin of less than 7 g/dl[1,8]

Iron deficiency (ID) is a status with no mobilizable iron stores leading to decreased iron supply to tissues due to long-term negative iron balance. Finally, the most significant negative effect of ID is anemia[2] which is linked to unfavorable outcome of pregnancy as preterm delivery, low birth weight, neonatal ID[4,7], low Apgar scores at 5 min[5].

Also suspected to lower oxygen to the fetus, making blood centrally distributed to preserve cerebral oxy genation[6,14] and asymmetrical IUGR. With no evidence of placental insufficiency documented yet[6].

WHO report, 2001 indicated that IDA is a significant problem throughout the world averaging 56% in developing countries while 14% in industrialized countries.[3,6]

ID has a negative impact on child intelligence and behavior. It's prudent to prevent ID in fetuses by preventing ID in the pregnant woman.[11]

IUGR is associated with increased perinatal morbidity, higher chance for neurodevelopmental impairment and increased incidence of adult diseases such as diabetes and cardiovascular disease [7]

IUGR is defined as "abdominal circumference >2SD below the mean for gestational age confirmed by serial assessment of the fetal growth parameters".[8]

Color Doppler in ultrasound machines provides a chance for noninvasive hemodynamic monitoring as it can reliably predict adverse outcomes in SGA fetuses [9], so surveillance with Doppler is done when suspecting IUGR [8]

Distribution of blood between the placental and cerebral regions determined with Cerebro-Umbilical ratio(C/U ratio) [7, 8]. Normally it's > 1.1, but decreases in case of hypoxia because of increase in placental resistance and cerebral vasodilation[9, 15]correlating closely with fetal growth, hypoxia, and behavior, prior to 34 weeks of pregnancy[2]

Perinatal morbidity of IUGR fetuses is greater than in normal ones. The umbilical artery and the MCA Doppler may be abnormal, without effect seen on growth until 26-32 weeks' gestation; mild utero-placental insufficiency [10]

Material and Method

This prospective comparative study included 521 pregnant women attended Kasralainy Maternity Hospital, from July 2019 to September 2019. Including patients aged 20-35 years with singleton living fetus ≥ 32 weeks' gestation on admission (calculated by LMP or by 1st trimester ultrasound), with hemoglobin levels below 109 g/L. Excluding patients in labor, multifetal pregnancy, medical disorder other than IDA as chronic hypertension, preeclampsia, D.M., hemoglobinopathies, or blood loss as placenta previa, congenital anomalies; after explaining the study, patients provided informed consent to participate and were subjected to:

1. **History:** Symptoms as weakness, LMP, obstetric code, mode of deliveries.
2. **Examination:** For pallor, tachycardia, fundal height, rupture membranes, cervical dilatation.
3. **Venous Samples:** CBC, serum ferritin.
4. **Ultrasonography:** For viability, placental site, estimated fetal weight (EFW), amniotic fluid index, using 3.5 MHz curvilinear transducer on (Voluson 58-GE ultrasound Seoul, South Korea) machine equipped with color-flow mapping, and a 50-Hz high-pass filter; measurements were performed in a semi recumbent position. Color-flow imaging was used to visualize the umbilical artery, renal artery and MCA. Pulsed Doppler was performed with a sample volume of 5 mm.
5. **Doppler Flowmetry:** the RI and S/D ratio of the umbilical artery, and the RI and S/D ratio of MCA, distribution of blood flow in the fetus was measured by C\U (C=MCA PI, U= Umbilical artery PI) and the RI of the renal artery were measured. For each, the mean of three measurements recorded

Venous samples and ultrasonography done on admission, repeated ten days after treatment and followed up till delivery (every 2 weeks till 36week then every week till delivery).

Group (A): mild anemia (Hemoglobin concentration: 90-109 g\L)**:** received oral ferrous fumerate therapeutic dose: 100-200 mg/d, iron was continued for 3 months to replenish stores, adequate replacement when ferritin reached 50 ng/ml, to maintain maternal stores and neonatal iron stores.

Group (B): moderate anemia (Hemoglobin concentration: 70-89 g\L): received iron sucroseparenterally**.**

The dose was calculated using the following formula according to product literature:

IV iron dose (mg) = blood volume (dl) x hemoglobin deficit x3.3

Blood volume (ml) = 65 ml x weight in kg (blood volume/kg = 65ml/kg)

Blood volume (dl) = blood volume (ml)/100 (each dl contains 100ml)

Hemoglobin deficit = difference between observed and desired hemoglobin. (desired hemoglobin 11g %)

3.3 = reflects the amount of iron (in milligrams) in each gram of hemoglobin.

Group (C): severe anemia (Hemoglobin concentration: >70 g\L): received blood transfusion in the form of packed RBC; each unit contains 200 ml RBCs, which contain 200 mg iron.

Statistical Method: An estimated minimum sample size of 521 participants was calculated using StatsDirect application Version 3.2.7 using a 95% confidence interval and a power of 80% and based on prevalence of IUGR in anemic population of about 79.2% [14]

The variables entered using Excel 2016 (Microsoft Corporation, Redmond, WA, USA) before transfer to SPSS (statistical package for the Social Sciences) version 25 (IBM Corp, Armonk, NY, USA) for Microsoft Windows (2010) where data entered for analysis. Data described in terms of range, mean □□standard deviation (□□SD) for quantitative data, number and percentages for categorical data.

Comparison between groups done using one-way analysis of variance (ANOVA) with post hoc multiple 2-group comparison test.

For comparing serial measurements within each group repeated measures ANOVA was used in normally distributed quantitative variables.

Within group; comparison of numerical variables done using paired *t* test in comparing 2 groups. *P* values less than 0.05 was statistically significant.

Results

Table (1): Summary of data.

Discussion

A significant difference in age, parity, mode of delivery and BMI between group (A), (B) and (C) demonstrated by the percentage of those aged ≥ 30 years in group (C) about 65.85% compared to 30% in (B) and 10% in (A) and the percentage of multiparous women was the highest in group (C) representing 90.24% also high in (B) forming 80% compared with 39.1% in (A).

Mode of delivery showed significant difference between the groups as the rate of CS among multiparous women was higher in group (C) about 81.08% versus 25% in (B) and 16.67% in (A), reflecting higher incidence of ID and IDA with increasing age and parity.

Prepregnancy or early pregnancy BMI measurement revealed higher percentage for underweight being 56.1% in group (C) versus 10% in (A) and (B).

Similar to what was stated: a significant relationship between parity and severity of anemia. Multiparas is more prone for severe anemia due to frequent pregnancies and inadequate spacing versus primigravidas.[5]

But not with the result which suggested that age and parity were independently associated with maternal anemia[13]

Regarding hemoglobin and serum ferritin, the major impact of treatment was in group (C) as the mean hemoglobin concentration was elevated by about 7 g% from admission till delivery; showing the impact of blood transfusion. Yet, hemoglobin in group (B) was elevated about 2.9 g%, while 2 g% in (A)

Ten days after treatment, they elevated and the difference was significant among all groups; a more rapid response may be to parenteral iron than oral iron.

At delivery, further elevation significant difference found between groups (A) and (B) reflecting that both oral iron and parenteral iron had almost a similar impact on hemoglobin and serum ferritin on the long run. Significant difference within the same group compared at time of admission, ten days after treatment and at delivery.

Similar to what stated: for women who required a rapid replacement of iron stores, intravenous iron sucrose is more effective than regular oral iron therapy[9]

IUGR occurred in 36.5% of the study population with the highest percentage in group (C) (73.17%) when compared with (A) and (B); a statistically significant difference between (A) versus (B) and (C) regarding mean EFW on admission and a significant difference between the groups regarding gestational age by dates and that by ultrasound on admission.

No significant effect in group (A) but a significant difference between all groups regarding AFI on admission and ten days after treatment and a potential benefit was the prevention of development of oligohydramnios as pregnancy advances especially in group (C) as there was a significant increase in AFI noticed in group (B) and (C) after treatment versus (A)

This doesn't agree with what stated: there was no significant increase in AFI after treatment [4]

Also as noted in this study that there was an increase in AFI in group (B), (C) ten days after treatment which correlated with a decrease in umbilical artery RI and renal artery RI; showing that increased perfusion in the umbilical artery and in the renal artery may be the cause.

Data regarding the umbilical artery RI and S/D ratio showed a significant difference between group (A) and the other two groups on admission, ten days after treatment with a higher RI in group (A); this might be attributed to the non-effectiveness of oral iron on short-term therapy. On the other hand, at delivery all groups showed improvement in the umbilical artery RI but still group (C) had the best chance. This result also points out to the effectiveness of blood transfusion on the long-term outcome.

Regarding renal artery RI, there was a significant difference between group (A) and other groups on admission and this may be attributed to the higher percentage of cases with IUGR in group (B) and in group (C) in whom IUGR is associated with decreased kidney size and nephron number and hence decreased urine production so decreased AFI which is similar to what has been stated by another studyas regards renal artery RI in cases of IUGR[13]

Ten days after treatment, renal artery RI decreased in all groups with a significant difference between group (A) and other groups. At delivery, the renal artery RI decreased in all groups with a significant difference between group (C) and other groups. This result also points out to the effectiveness of blood transfusion on the long-term outcome.

Similar to what stated: increased impendence to blood flow in the umbilical arteries and the fetal renal arteriesin severe IUGR associated with hypoxemia [15]

The C\U ratio, in group (B) & (C) were below the normal range, reflecting that the fetus adapted by blood flow redistribution towards the brain then corrected by the increase of both the cerebral resistance index and the C/U ratio after blood transfusion and parenteral iron evidenced by a significant difference between all groups regarding mean C/U ratio ten days after treatment.

In group (A), the C/U values were within normal reflecting that the blood flow distribution between the brain and placenta was normal despite being anemic one.

This agrees with: Distribution of fetal blood flow (between the placental and cerebral regions) is determined with C/U ratio, which is the ratio between the cerebral and umbilical pulsatility index. This parameter is always >1.1 during normal pregnancy, but decreases in the case of hypoxia because of increase in placental resistance and cerebral vasodilatation[9]

This agrees with other study which showed similar impact of blood transfusion and parenteral iron on Doppler indices [4]

A statistically significant difference between the MCA RI and MCA S/D ratio among the groups on admission. Ten days after treatment, RI increased in group (B) and group (C) with a significant difference between them and group (A). At delivery, it further increased in group (C) with a significant difference between the groups.

Specific MCA Doppler changes were evaluated specifically MCA PSV and PI in IUGR fetuses. They found that while an abnormal PI preceded an abnormal PSV, the PI demonstrated an inconsistent pattern. MCA-PSV, however, consistently showed an increase in velocity and immediately prior to demise, concluding that MCA-PSV is a better predictor of IUGR-associated perinatal mortality than any other measurement [8]

Regarding MCA PSV as suggestive of fetal anemia due to increased blood velocity; may be an area for future research in this topic to show whether maternal IDA may cause fetal ID and fetal anemia or not aided by cordocentesis to diagnose fetal anemia by hemoglobin level and hematocrit concentration in fetal blood.

Absent end-diastolic flow velocities of the renal artery should be considered suspicious for fetal hypoxia especially if oligohydramnios is documented, it was found that IUGR fetuses with oligohydramnios have a PI above the established values for the 95th percentile. The combination of IUGR, oligohydramnios and elevated PI of the fetal renal artery seems to be associated with an increase in perinatal morbidity and mortality [8, 13]

Preterm labor occurred in 7.1% of the study population being highest in group (C) (24.39%) versus group (A) and group (B) evidenced by a significant difference in gestational age at delivery among all groups.

At delivery, the highest mean neonatal birth weight was in group (A) versus group (B) and group (C) but the difference was not significant.

Neonates of group (C) showed lower mean APGAR scores at 5 min. versus group (A) and group (B) and the difference was significant with no cases needed NICU admission in group (A), while five cases (2%) in group (B) and four cases (9.8%) in group (C) admitted.

This agrees with what stated: severe iron deficiency anemia is associated with poor pregnancy outcome including increased risk of IUGR and preterm labor [12]

Abstract

New imidazole contains, oxazole and thioxoimidazolidin were synthesized by using simple method**.** All compounds were synthesized by using Derivatives aniline as stating material which was obtained from Furfural and Sodium nitrite with. Hydrochloric acid derivatives (S_4, S_5) was obtained from reaction (S_4, S_5) with Thiosemicarbazide while reaction of (S_{11}, S_{12}) with add chloro ethyl acetate derivatives (S_{18}, S_{19}) were obtained reaction of Benzene sulphonyl chloride was reacted with (S_{18}, S_{19}) Triethylamine were get (S_{25}, S_{26}) finally reaction of acetyl chloride was reacted with ($S_{25,}$ S_{26}) Triethylamine were get (S_{32}, S_{33}) FTIR, 1HNMR, GC MASS spectra and molecular docking were used to characterized derivatives

Several bacterial species like *S.aureus, S Epidermitis, Escherichia Coli* and *Klebsiella Sp*were used to tested antibacterial activity .

All the synthesized compounds having promising docking results with COX-2 active site as shown in Compound (, $S_{12,}$ $S_{18,}$ $S_{26,}$ $S_{19,}$ S_{32} and S_{33}) showed H-bond interactions with Arg121 and Tyr356 and these two amino acids exist in the binding with five approved NSAIDs .These compounds have H-bond with Arg121 and Tyr356 which is the binding site of diclofenac, lumiracoxib, tolfenamic acid.

Keywords: *Imidazole, Schiff base thioxoimidazolidin.*

Introduction

The most common Heterocyclic were found good biological molecules like imidazole.[1] containing heteroatoms like nitrogen (N), oxygen (O), or sulfur (S) The best known of the simple heterocyclic compounds are furan, and thiophene molecules with five and six membered rings mostly are high activity .[2-5]. All natural products with heterocyclics are important in biologically and molecular docking active system[6] and medicinal to approved drugs. imidazole derivatives in heterocyclic chemistry considered most important compounds and drugs used as antibiotics, anticancer,[7] anti-tubercular,[8] antibacterial,[9] antifungal,[10] anti-HIV,[11] anti-inflammatory,[12] antioxidant,[13] antimicrobial,[14] and anti-ulcer[15].

Method

General procedure for the synthesis of 5-Arylfuran-2-carbaldehyde (S_4, S_5): These compounds were synthesized characterization the procedure in reference [16]. 4-Substituted aniline (0.272 mole) a mixture of concentrated HCl (67.4 m L) and H_2O (45 mL). The solution to 0ºC with Sodium nitrite (19 g, 0.276 mole) dissolved in H_2O (50 ml). The solution was stirred for 20 min, refinement and then furan-2-carboxaldehyde (30.8 g, 0.32 mole) in H_2O

(100 mL) was added with a solution of Cu -Cl_2 H_2O(5g, 0.08mol) in H_2O (50 mL) at a temperature of 10–12 C. The reaction mixture was slowly warmed up to 35C recrystallized from ethanol.

Synthesis of (2-((5-Arylfuran-2-yl) methylene) hydrazine-1-carbo-thioamide)(S_{11}, S_{12}): To compound derivatives (5 Aryl furon-2-carbaldehyde) (S_4, S_5), (0.01 mole in 30ml ethanol) at room temperature, (2-3) drop from glacial acetic acid was added. The mixture was stirred for (10min) and add thiosemicarbazide (0.01mole, 0.009gm). The mixture was refluxed for (12hrs). The reaction is allowed to cool, then the mixture was poured in to crushed ice and recrystallized from ethanol or methanol to yield desired compound[17].

Synthesis of (1-(((5-Arylfuran-2-yl) methylene) amino)-2-thioxoimid-azolidin-4-one) (S_{18}, S_{19}): To compounds (0.02mole) (S_{11}-S_{12}) in 30ml (1,4-dioxane) at room temperature Sodium bicarbonate was added (0.02mole,0.645gm) with stirred for (30min) and added Ethyl chloro acetate (0.02mole,2.46gm). The mixture was the refluxed for (30hrs). Then powered into ice water. After that the precipitate filtered off and the solid was recrystallized by using dioxane to yield the desired compound. [18]

Synthesis of ((Z)-1-(((5-Arylfuran-2-yl) methylene) amino)-3-(phenylsulfonyl)-2-thioxoimidazolidin-4-one) S_{25} _ S_{26}: Compounds (S_{18} _ S_{19})(0.001mole) in 25ml of (1, 4-dioxane) stirring for (10 min). Triethylamine Et_3N was added with stirring for (1hr) in ice bath and then added benzene sulphonyl chloride (0.001mole, 0.176 gm) to a stirred solution of compound. The mixture was the refluxed for (22hrs)(at 120 ºC).

Synthesis of ((Z)-3-acetyl-1-(((5-phenylfuran-2-yl) methylene) amino)-2-thioxoimidazolidin-4-one) compounds S_{32}_ S_{33}: Compounds (S_{25} _ S_{26})(0.001mole) in 25ml of (1, 4-dioxane) stirring for (10 min). Triethylamine Et_3N was added with stirring for (1hr) in ice bath and then added acetyl chloride (0.001mole, 0.078gm) to a stirred solution of compound. The mixture was the refluxed for (10 hrs.) 110 ^{0}C

Results and Discussion

		HIS90	1	2.972

Conclusions

The compounds were synthesized by using Derivatives aniline as starting material which was obtained from Furfural and Sodium nitrite with. Hydrochloric acid to give derivatives aldehyde the compound against different pathogenic bacteria and yeast were achieved using 125 µg/ml concentration as illustrated. The effect of compounds **(S_{11}, S_{12}, S_{18}, S_{19}, S_{25}, S_{26}, S_{32}, S_{33})** was evaluated against *Staphylococcus aureus and Staphylococcus Epidermitis Escherichia Coli* and *Klebsiella Sp*. All the synthesized compounds are promising docking results with the COX-2 active site as shown in Compound (, S_{12}, S_{18}, S_{26}, S_{19}, S_{32} and S_{33})

Effect of Fortifying Whole Wheat Flour with Frankincense Powder as a Good Nutritional and Antioxidant Source

Abeer Ghazi ALmasoudi

Food Science Department, College of Science, Taif University, Branch of the College at Turbah, Saudi Arabia

Abstract

This research was to supplement the whole wheat flour with frankincense to produce a high nutritional value of biscuits at 2, 4 and 9%, respectively. The chemical composition of Boswellia frankincense and it is blends biscuits and also nutritional, physical, functional and sensory qualities of biscuits fortified product were determined.

The results showed that, Boswellia frankincense powder rich in content with essential oil. In a related the results showed that, chemical composition is higher in different biscuits blends. The sensory characteristics were non - significant decrease in total general acceptance. Similar results in the functional and physical properties were found of the resulting biscuit samples. Generally, all supplemented levels of frankincense powder showed acceptable results in the sensory, physical and functional characteristics in biscuits with a significant improvement in the nutritional qualities.

Keywords: *Boswellia frankincenser, whole wheat flour, essential oil, antioxidant.*

Introduction

Nowadays, consumers are increasingly recognizing the need to eat functional foods that contain nutrients that provide additional health benefits besides basic nutritional needs[1]. Whole meal wheat flour had contained basically rich fiber, minerals, vitamins, and natural antioxidants than white flour. Thus whole cereal wheat flour is assumed to be as an excellent source of nutritional constituents for people's health with many other benefits[2]**.** The whole meal wheat flour acceptable processing from cereal products which appearance an increased nutritional balance. Utilize the active role of cereals is hopeful for the processing of functional products whose specific advantage will have to be appearances [3].

Bakery products are the greatest public processed food in the global[4]. Among that, biscuits considered the most group of snack foods between bakery products for the reason that they are prepared from simple and easily able to be used raw materials. They are more consumed for the reason that they have a very able to be agreed with taste. Therefore, there is the most necessary to become better their nutrient value to feed poorly nourished people as well as children [5]**.**

Frankincense is a famous material that Sold and located in the stores of Arab herbs and medicinal herbs and uses Frankincense in traditional medicine to treat many diseases. Chemically, frankincense consists of colloidal acids (56-65), gum materials (20 -36%), volatile oils (4 - 8%), respectively[6]**.**

The objective of this research was to assess the influence of frankincense powder addition on whole wheat biscuit targeting good sensory acceptance with high nutritional value.

Materials and Method

Materials: Wheat seeds were obtained from Grain Soils and Flour Mills Organization at KSA. Frankincense powder and other ingredients were purchased from the local market at Jeddah, KSA.

Method

Preparation of whole wheat flour and its blends: Wheat seeds were milling to give powder and sieving through a 60 - mesh sieve to obtain symmetric flour as recommended by **Hallab *et al.*[7]**.

Whole wheat flour was well blended with frankincense powder at levels 2, 4 and 9% to produce biscuits. The control was also prepared with 100% wheat flour. The biscuits were baked at 170-180°C for 12 min.

Chemical analysis of frankincense and biscuits: Alcohol-soluble resin, water soluble gum and essential oil fractionated using GC-MS were determined in frankincense according to **AOAC[8]**. Biscuits and its blend were chemically analyzed for moisture, ash, lipids, fiber and protein contents according to **AOAC [8]**.

Sensory evaluation of biscuit: Biscuit produced using suggested blends were evaluated for their sensory characteristics by ten panelists mentioned by **AACC [9]**.

Texture analysis of biscuits:

Hardness and Breaking strength were measured by using texture analyzer

Physical and color properties of biscuit:

Sai-Manohar and Haridas-Rao[10] was calculated the thickness (mm), spread ratio (mm), thickness (mm), weight (g), volume (cm) and specific volume (cm^3/g) was measured in different blends biscuits.

Color (L^*, a^* and b^*values) of the biscuits was determined by using hunter colorimeter

Functional properties: Bulk density was determined by **Wang and Kinsella[11],** water absorption capacity and index by **Anderson[12],** dispersibility by **Kulkarni [13]**, swelling power and solubility index by **Takashi and Seib [14]**.

Phytochemical and microbiological assay: Antioxidant activity, flavonoids, polyphenolic and tannin were determined by **AOAC[8].** Total bacteria count and yeast and mold were assayed according to**[15].**

Statistical Analysis: All the obtained data were statically analyzed by SPSS computer software**[16]**.

Results and Discussion

Chemical composition of Boswellia frankincense: The result from Table (1) showed that the frankincense resin contains 8.0% essential oil, 60.8% alcohol-soluble resin, 23.4% water soluble gum and 9% other active compounds. The GC-MS analysis of frankincense essential oils observed that the major components were methylchavicol, α-thujene and α-pinene (11.0, 10.0 and 8.2%, respectively). These results are confirmed with **[17]** found that Boswellia resin had contained about 5-9% essential oil, 65-85% alcohol-soluble resin, and the residual 21-22% is water-soluble gum. Also, they indicated that the Boswellia resin oil consists of major compounds were α-thujene, α-pinene, sabinene and methylchavicol (12.0, 8.0, 3.8 and 11.6% respectively).

Table (1): Chemical composition of Boswellia frankincense

Components		**%**
Alcohol-soluble resin		60.8
Water soluble gum		23.4
Essential oil		8.0
The major component of the essential oil	α-pinene	8.2
	α-thujene	10
	Sabinene	1.9
	β-pinene	0.8
	Myrcene	3.5
	α-phellandrene	0.8
	Limonene	2.0
	Methylchavicol	11.0
	Cembrenol	1.8
Other active compounds		9.0

Chemical composition of biscuits with frankincense: The present results from Table (2) revealed that the biscuits with frankinens recorded the highest result in ash, fiber and lipids were 1.44, 2.46 and 19.32% for 9% frankinens biscuits compared with 1.36, 2.41 and 18.68% for control samples biscuits

Meanwhile, the highest value of crude protein was recorded for control samples followed by biscuits with 2% frankinens being 11.42 and 11.30%, respectively. These results are agreement by **Al-Harrasi *et al.*[18]** found

that, the proximate analysis of Boswellia were from 6.25 to 10.65% for moisture, From 1.02 to 6.66% for ash, from 0.25 to 1.14% for protein, from 13.30 to 24.8% for carbohydrates and from 71.56 to 77.38% for lipids.

Table (2). Chemical composition of biscuits with frankincense.

Samples	Moisture	Protein	Lipids	Ash	Fiber	Carbohydrate
100% WWF Control	3.84[a] ±0.12	11.42[a] ±0.38	18.68[b] ±0.58	1.36[a] ±0.03	2.41[a] ±0.13	66.13[a] ±1.12
2% Frankincense	3.83[a] ±0.09	11.30[a] ±0.23	18.88[b] ±0.29	1.38[a] ±0.06	2.39[a] ±0.08	66.05[a] ±1.23
4% Frankincense	3.85[a] ±0.13	11:22[a] ±0.12	19.03[ab] ±0.19	1.42[a] ±0.10	2.43[a] ±0.17	65.90[a] ±1.22
9% Frankincense	3.90[a] ±0.11	10.96[ab] ±0.10	19.32[a] ±0.49	1.44[a] ±0.08	2.46[a] ±0.19	65.86[a] ±0.90

Sensory evaluation and texture analysis of biscuits with frankincense: From the results sensory evaluation in Table (3) and Photo (1), it could be seen that no significant variations ($p>0.05$) among control biscuit sample and biscuit sample contained 2% level of frankincense powder for taste. While significant differences ($p<0.05$) were recorded in the control biscuit and biscuit which prepared by using 4 and 9% frankincense powder.

The color acceptability score for control, and biscuit made from blends containing 2, 4 and 9% frankincense powder were 18.3, 18.5, 18.7 and 18.7, respectively. Changes in color and taste in biscuit may be due to aroma volatiles in frankincense powder. Biscuit color improvement with increasing frankincense powder due to the frankincense essential oil which was light yellow[19].

The biscuit hardness in the same table was increased at 2% frankincense powder levels but again a lowering was shown at 4 and 9% frankincense levels. Higher fiber content in frankincense powder than whole wheat flour perhaps refers to elevating hardness of the biscuits in proportion to 2% frankincense powder. Although, the high levels of fat content was increased in frankincense led to decreasing the hardness of biscuits made of 4 and 9% frankincense powder than control samples. These results confirmed with **Emami *et al.*[20]** who found that, the hardness of biscuits increasing as a result of fat reduction.

Photo (1): Biscuit with frankincense powder

Table (3): Sensory evaluation and texture analysis of biscuits with frankincense

Samples	Hardness (g)	Breaking strength (Load in g)	Color	Taste	Odor	Appearance	Crunchines	Total
100% WWF	2395^{b} ±4.52	360^{a} ±1.16	18.3^{b} ±0.17	19.7^{a} ±1.19	19.9^{a} ±1.00	18.5^{a} ±0.89	18.6^{a} ±1.05	95.0^{a} ±1.57
2%F	2411^{a} ±3.78	362^{a} ±2.02	18.5^{a} ±0.82	19.4^{ab} ±1.52	19.0^{b} ±0.72	18.25^{a} ±0.82	18.45 ±0.41	93.5^{a} ±3.89
4%F	2269^{c} ±6.18	322^{c} ±2.45	18.7^{a} ±0.72	18.4^{ab} ±0.72	18.7^{c} ±0.56	18.75^{a} ±0.65	18.45^{ab} ±0.99	92.8^{a} ±2.56
9% F	2201^{d} ±5.19	287^{d} ±1.96	18.7^{a} ±1.29	17.8^{b} ±0.94	18.7^{c} ±0.56	18.35^{a} ±0.32	18.3^{ab} ±0.78	91.7^{a} ±1.92

Physical and color characteristics of biscuits with frankincense: From the results in Table (4), it could be observed that, the control sample biscuits had a weight of 61.58g and volume 205 cm^3 with specific volume of 3.33 cm3/g. The replacement of whole wheat flour with different levels of frankincense powder caused gradual slightly increase in the weight of prepared biscuit parallel with increasing the level of substitution. The making greater in biscuit weight could be the reason for the whole meal wheat has contained rich amounts from fiber content which characterized by great water holding capacity[21].

Moreover, there were no significant variation ($p>0.05$) in volume and specific volume between control and biscuit sample which substituted with frankincense powder except biscuits made of 9% frankincense powder was decrease in volume. Also, the obtained results showed that the average thickness value of the control biscuit sample was 8.7 mm and it showed non-significant decrease with increasing frankincense powder levels.

The results in a Table (3) showed that the *L** degrees of biscuit samples lowering while *a** degree was elevated with increasing the ratio of frankincense powder, but *b** degrees trended non - significant decrease except biscuit with 9% frankincense powder which showed significant decrease compared with the control samples. The slightly reduction of *L** degrees and increased *a** degrees didn't affect the darkening of the biscuit. The slight improvement in color was interpreted as a color of frankincense oil (light yellow) as[19] found; it was dependant on the fortification level.

Functional properties of biscuits with frankincense: The results from Table (5) showed that the water absorption index ranged from 4.01 to 3.49 whilst the water absorption capacity ranged between 92.5 to 94.2%. The water absorption capacity of the wholemeal wheat flour was decreased than different blends, this could be confirmed that the addition of frankincense powder to wheat flour give high water binding capacity, which in turn to become better the reconstitution ability[22]. The solubility index and swelling power of the flour samples ranged from 9.92 and 10.29 to 8.88 and 9.89%, respectively. **Moorthy and Ramanujam[23]** observed that the swelling power of flour granules is a significance of the extent of associative forces within the granule. The value of dispensability was increased in blends from 74.3% in control biscuits to 75.6% in different biscuits blends. Thus, they will easily reconstitute to lead fine consistency dough through mixing [24].

The bulk density of the flour samples ranged between 0.64 and 0.71 g cm-3. The bulk density is mostly influenced by the particle size and the density of flour or flour blends and it is quite significant in determining the packaging need, raw material treatment and usage in wet processing in the food industry[22].

Phytochemical and antimicrobial activity of different biscuits: Table (6) indicated that the results phytochemical activities are shown that increase significantly with increasing addition of frankincense powder to whole wheat flour to produce of biscuits. This is due to frankincense contained a high percentage of antioxidants. **Masoud *et al.*[25]** found that frankincense had contained rich amounts from antioxidant components showed that higher activities. Thus, frankincense can also be utilized as an antioxidant complement.

Table (4): Physical and color characteristics of biscuits with frankincense

Physical Prorertie	100% WWF Control	2% Frankincense	4% Frankincense	9% Frankincense
Weight (W) (g)	61.58^{c} ±1.6	61.82^{b} ±1.02	62.11^{ab} ±2.26	62.43^{a} ±0.92
Volume (cm3)	205^{a} ±2.65	197^{a} ±2.77	193^{ab} ±3.12	187^{b} ±4.15

Spread ratio W/T	5.24^{a} ±0.19	5.35^{a} ±0.20	5.41^{a} ±0.30	5.38^{a} ±0.62
Color Biscuits				
L	58.40^{a} ±1.00	57.59^{b} ±1.36	57.05^{c} ±1.19	56.99^{d} ±0.79
a	11.44^{b} ±0.58	11.59^{b} ±0.82	11.85^{a} ±0.41	11.99^{a} ±1.32
b	18.67^{a} ±1.02	18.41^{a} ±1.18	18.31^{ab} ±0.72	18.01^{b} ±0.42

Table (5): Functional properties of different biscuits blends

Sample	Water absorption index	Solubility index	Swelling power (%)	Water absorption capacity (%)	Dispersibility (%)	Bulk density (g cm^{-3})
100% WWF	4.01^{a} ±0.06	9.92^{a} ±0.42	10.29^{a} ±0.22	92.7^{c} ±1.03	74.3^{b} ±1.18	0.69^{a} ±0.05
2%F	3.94^{a} ±0.12	9.84^{a} ±0.39	10.02^{a} ±0.33	92.5^{c} ±0.99	75.6^{a} ±2.05	0.64^{a} ±0.09
4%F	3.48^{b} ±0.09	9.87^{a} ±0.57	10.19^{a} ±0.14	93.8^{b} ±0.67	75.4^{a} ±1.58	0.71^{a} ±0.03
9% F	3.49^{b} ±0.05	8.88^{b} ±0.12	9.89^{ab} ±0.19	94.2^{a} ±1.92	75.5^{a} ±0.96	0.64^{a} ±0.10

The antimicrobial activity in the same table indicated a decrease of the total count and a total colony of yeast and mold of biscuit blends with increasing frankincense powder from 2% to 9%. The biological activity of frankincense resins may be caused the volatile oil and their derivatives[26].

Conclusion

It could be concluded that the frankincense powder was added at different levels from 2 to 9% and the resulting biscuits had contained the highest amount 9% of frankincense showed that the lowest value in overall acceptability. Biscuits with 2 and 4% frankincense were without a sufficiently changed in physical and sensory characteristics. Incorporation of frankincense in formulation markedly increased the antioxidant content and antimicrobial activity.

Abstract

Purpose: Purpose: This study aimed to investigate the effects of high-power pain threshold ultrasound versus conventional ultrasound on upper trapezius myofascial trigger points. Method: Seventy participants with active trigger points were randomly divided into three groups, groups A, B and C. Group A (n=23) received high-power pain threshold ultrasound twice/week for two weeks. Group B (n=24) received conventional ultrasound twice/week for four weeks. Group C (n=23) (control group) received sham ultrasound twice/ week for four weeks. Visual analogue scale (VAS) scores, surface electromyography were used to evaluate participants pre and post-treatment. Results: According to the within-group analysis, there were significant differences in all variables between pre- and post-treatment in the three groups ($p<0.05$). The between-group analysis revealed a significant decrease ($p <0.001$) in the normalized resting electromyographic (EMG) activity of the left trapezius after treatment in group A compared with group C. Groups A and B had significantly greater decreases in VAS scores after treatment than group C ($P<0.005$). In addition, group A had significantly lower VAS score after treatment than group B. Conclusion: Both techniques of ultrasound are effective for the treatment of subjects with active trigger points, but high-power pain threshold ultrasound is superior.

Keywords: *High-power pain threshold ultrasound, conventional ultrasound, surface electromyography, myofascial trigger points.*

Introduction

Myofascial pain syndrome (MPS) is a type of chronic pain disorder that affects a portion of the population that is characterized by the existence of trigger points. Trigger points are hyperirritable loci inside a tight band of skeletal muscles and are commonly observed in the upper fibres of the trapezius due to overload and microtrauma.[1] Trigger points are clinically categorized as latent or activemyofascial trigger points (MTrPs), Pain and increased resting myoelectric activity are present for active MTrPs. in individuals with active trigger points, consistent with a previous neurophysiological study.[2]

The production of heat is the main and most widely recognized effect of ultrasound (US), which is considered one of the most common techniques that used for the treatment of MPS. The thermogenic effect of US leads to a transient increase in the flexibility of dense collagenous structures which subsequently reduces joint stiffness, pain and associated muscle spasms and momentarily increases circulation.[3]

Previous studies that examined the effect of US for treatment of MPS have commonly administered as

Corresponding Author:
Ibtsam A. Ali
Lecturer, Basic Science Department, Faculty of Therapy, Cairo University
e-mail: ibtsammohmed83@yahoo.com

conventional US which is between 0.8- 1.5 watt/cm², which has improved MPS.[4,5]

Some studies have also evaluated another type of US therapy, namely, high-power pain threshold ultrasound (HPPTUS), and have reported that it is effective in the treatment of MPS.[3,4,6]

To date, few studies have investigated the effect of US on EMG activity in MPS. Therefore, this study provides new insights and major contributions regarding the effect of US on EMG activity in MPS.

The current study aimed to compare the effects of HPPT and conventional US therapy on pain, myoelectric activities in individuals with upper trapezius active trigger points.

Materials and Method

This randomized clinical trial was performed at the Laboratory of Electromyography, Faculty of Physical Therapy, Cairo University. The study protocol was approved by the research ethics committee of the Faculty of Physical Therapy (NO: P. T. REC/012/001519) and registered in the Pan African Clinical Trial Registry. (Registry ID PACTR 201712002882400).

Sample Size Calculation: The minimum required sample size was calculated to be 20 patients per group. This calculation was designed to reveal an effect size of 0.5 with an alpha of 0.05 and a power of 80% considering the visual analogue scale (VAS) score as the primary outcome. Based on the sample size estimation while considering a probable dropout rate (10%) and our available resources for conducting this study, we aimed to include 70 patients. The number of patients was calculated using G*Power (version 3.1.9.2) (Franz Faul, Uni Kiel, Germany).

Participants: Seventy participants their ages ranged from 18 to 30 were provided verbal and written explanations of the purpose of the study. If the participant agreed to participate, he or she signed a consent form that was approved by the Faculty of Physical Therapy. Then, the participants were randomly allocated to the following three groups by software randomization (1:1 allocation ration) using randomly permuted block sizes created with a random number generator: Group (A) received HPPT-US on the bilateral upper trapezius in four sessions at 3-day intervals. . Group (B) and group (C) received conventional and sham US respectively on the bilateral upper trapezius for four weeks twice per week.

Inclusion and exclusion criteria:

Participants were included if they had active MTrPs in the upper trapezius muscle bilaterally and complained of pain at rest, jump sign at pressure, had a limited range of motion (ROM), or experienced referred pain.[7] Participants were excluded if they had a history of any degenerative disorders, cervical disc hernia or fibromyalgia that might cause pain or if they had MPS and had received any therapy within the previous 6 months. Heavy manual laborers and patients who regularly performed physical exercises, had any systemic diseases, had previous neck or shoulder surgery, or had any contraindication for US therapy were also excluded.[5]

Instrumentation:

Assessment Instrumentation: Pain intensity was assessed using the VAS. The scale is presented as a line: one end of the line corresponds to no pain, and the other end of the line corresponds to the worst possible pain. Use of the VAS is a valid and reliable method for assessing pain intensity. Each participant was instructed to put a point on the line to identify the pain intensity. [8]

Myoelectric signals were identified bilaterally from the upper trapezius muscle by usinga two-channel digital electromyogram device (Neuro-EMG-Micro, Neurosoft, Ivanovo, Russia).

Treatment Instrumentation: The equipment used for US for all groups was a Med Serve system (England NN114HE, Prosound/ULS-1000, S/N: U0547).

Procedures: Group (B) received a standard dose of US therapy (conventional US) in continuous mode (1 MHz, intensity of 1.0 W/cm²) during which the head of the US device was moved in a circular motion over the trigger point for 5 min.[9] Group (C) received sham US, which involved the same procedures as conventional US except that the US device was switched off. Group (A) received HPPT-US using the same device in the same mode and at the same frequency. The probe was held fixed over the trigger point, and the US dose was increased until intolerable pain was felt by the participant. The probe was held fixed for 3 s at the dose at which intolerable pain was felt, and then, the dose was decreased by half. At this dose, the probe was moved in a circular motion over the trigger point and the surrounding

area for 15 s, and then, the dose was increased a second time in a similar manner. The maximum dose that could be given to this group of patients for 3 s ranged from 1.5 to 2.5 W/cm². [3,6] The same technique was repeated three times, and the treatment session ended.

The EMG electrodes were two recording electrodes (one active and one reference) placed parallel to the upper trapezius muscle with a 2-3 cm distance between them, and the ground electrode was wrapped around the wrist joint. [10]The skin covering the area of the upper trapezius muscle and the wrist joint was carefully cleaned with alcohol. Then, the recording electrodes were positioned 2 cm lateral to the centre of a line drawn from the c7 spinous process to the posterolateral aspect of acromion bone. The test was performed with the patient seated in a chair, and the participant was asked to maintain the trapezius muscle in a resting position for six seconds followed by elevating both shoulders, retaining this position in isometric contraction for six seconds, supported by suitable verbal commands. The participants had been previously taught how to perform the required tasks. Each task was performed 3 times with one minute rest intervals, and the root mean square (RMS) value was used. [11]

Normalization of EMG activity: Normalized values were calculated as follows: Normalized RMS %=EMG amplitude during resting/(average of EMGMAX for the 3 trials)×100. [12]

Statistical Analysis: Data analysis was performed using the SPSS 23.0 for Windows statistical software. In the beginning, the normality of data distribution was tested through the Shapiro-Wilk test. Descriptive data for participants, characteristics and dependent variables was calculated as mean ± SD. Because of skewed distributions, the EMG parameters were square root-transformed before analysis. 2x3 mixed model MANOVA was carried out to compare the three groups (between-subject effect) at each of the before and after test time periods and between the before and after test time periods (within-subject effect) for each group for the outcome variables. Furthermore, testing for the interaction effects between both independent variables was conducted. The alpha level of significance was adopted at P< 0.05.

Results

The demographic characteristics of the participants are shown in table (1), There was no significant difference in the mean age, weight, height and BMI between the three groups (p > 0.05). Also, there was no significant difference in sex distribution between groups (p = 0.25). Compared group C, mixed-model MANOVA revealed a significant decrease in the mean value for normalized resting EMG after treatment in Group A (HPPTUS) (P =0.017, CI: -0.96 - -0.073). Regarding pain, the decrease in the mean values for VAS score was significant in Group A and B after treatment as compared to group C (Group A VAS: P<0.001, CI: -3.66 - -1.98; Group B VAS: P<0.001, CI: -2.26 - -.60), as shown in table (2). In addition, the results showed significant decrease in the mean values for VAS in Group A as compared to Group B after treatment (VAS: P<0.001, CI: -2.22- -.56 and NDI: P=.011, CI: -5.47 - -.65), as shown in table (2). Moreover, the mean values for VAS score, normalized resting EMG activity of the right and left trapezius muscle decreased after treatment compared with before in the three groups, as shown in table (2).

Table 1. Demographic characteristics of participants in the three groups

		HPP US	Conventional US	Sham US	p-value
		Mean ± SD	Mean ± SD	Mean ± SD	
Age (years)		21.65 ± 3.61	21.41 ± 2.43	21.65 ± 2.72	0.95
Weight (kg)		67.08 ± 7.65	68.04 ± 6.92	68.26 ± 7.4	0.84
Height (cm)		162.65 ± 5.19	162.91 ± 6.65	163.34 ± 5.66	0.92

Discussion

This study aimed to compare the effect of HPPT-US with that of conventional US in participants with upper trapezius active MTrPs. The present study showed significant improvements in all three groups, but the superiority for the HPPT US group.

Our results are in agreement with those reported by Majlesi and Unalan (2004)[6] who found that HPPTUS is more effective than conventional US for the treatment of MPS according to VAS score and neck active lateral bending ROM. Koca et al. (2014)[4]alsocompared the effects of US treatment applied at low-, medium, and high-power doses on trigger points and found that, in general, HPPT-US therapy was more effective than other techniques.

In contrast, Esenyel et al. (2007) [13] found no significant difference between HPPTUS and conventional US in the treatment of trigger points with respect to VAS score, as Kim et al., 2014 [9]also reported no significant difference in VAS score between HPPTUS and conventional groups of elderly patients with latent MTrPs. This discrepancy from the results of the current study may be due to different ages and types of MTrPs.

The current study showed decreased normalized resting EMG activity of the muscle in all groups. Few studies have reported decreased basal electrical activity and fewer local twitch responses of the trapezius muscle after treatment with US.[14,15]The results of these previous studies are in agreement with those of the current study, as we found significantly decreased normalized resting EMG activity after treatment in both treatment groups. In contrast,another study found no effect of static US on EMG activity in the treatment of individuals with chronic neck pain. [16]

The current study showed significant improvements in normalized resting EMG activity of the left side in the HPPT-US compared with control group, on my point of view, the improvements were significant in the left side as most participants were right handed so, the muscle on the left side was more relaxed than right side.

Interestingly, the improvement observed in the HPPT and conventional US groups may be due to the thermogenic effect of US.[3]The effects of HPPTUS may be also due to the high intensity of US stimulation, which has been reported to decrease evoked action potential amplitude and exert an accompanying thermal effect. [17]The improvement observed in the control group may be due to the compression and massaging effect of the US probe. [18]

In the current study, all of the measures that were evaluated showed a significant improvement, while greater improvement was found in the HPPT-US group.

Therefore, HPPTUS is more economical treatment than conventional US treatment due to the reduced number of required treatment sessions.

Limitations: This study was limited by the short treatment time, and there was no follow-up evaluation.

Conclusion

Both conventional and HPPT-US techniques are effective for treating subjects with active trigger points of the upper trapezius muscle, while HPPT-US is more effective.

Deltoid Splitting Approach for the Treatment of Proximal Humeral Fractures

Mohamed Adel[1], Ahmed Lymona[1], Mohammed Mousa[1]

[1]Consultant of Orthopedic Surgery, Orthopaedic Department, Al Kasr Al Ainy Hospital, Cairo University, Cairo, Egypt

Abstract

Purpose: We evaluated the assessment of clinical, functional and radiological outcomes of the patients using deltoid splitting approach in fixation of proximal humeral fractures.

Method: Prospective study during the period March 2015 –January 2018 in level 1trauma center, Twenty three (23) patients underwent treatment of proximal humeral fractures using deltoid splitting approach. Out of these three (3) cases were excluded from the study as they had shoulder hemiarthroplasty (2 cases and one side of bilateral fractured patient), in one of the cases there was intraoperative humeral head split which was not diagnosed preoperatively and so, it was excluded from the study. This study group comprised 11 men and 9 women, with a mean age of 49 years (range 20–77). Patients were followed up for a minimum of one year (12-15 months).

Results: We measured the humeral shaft angle (HSA) and the humeral head height (HHH) to assess theradiological outcome the results were: 17 patients had adequate HSA in postoperative x-rays and 3 patients had inadequate HSA, 12 patients had adequate HHH and 8 patients had inadequate HHH. We used The Constant shoulder score to evaluate the functional outcome. The twenty cases which are included in the study the results were: 10 patients were excellent, 8 were good and 2 had fair constant score.

Conclusion: Deltoid splitting approach is a successful method for treating proximal humeral fractures regarding to clinical and radiological outcome. Anatomical reduction of the fracture and rigid fixation is important to save satisfactory functional outcome.

Keywords: *proximal humeral fracture, deltoid splitting approach.*

Introduction

Proximal humeral fractures are the second most common fractures in the upper extremity and the third overall most common fracture, after hip fractures and distal radial fractures, in patients older than sixty-five years of age[1].

Although the majority of proximal humeral fractures are either non displaced or minimally displaced and can be treated with sling immobilization and physical therapy, approximately about 20% of displaced proximal humeral fractures may benefit from operative treatment.

Many techniques have been described in surgical treatment of these fractures, but no single approach is considered to be the standard of care. Surgeons involved in treating proximal humeral fractures should be able to identify the fracture pattern and select an appropriate management of this pattern regarding bone quality.

Orthopaedic surgeons should have experience with many techniques, including transosseous suture fixation, closed reduction and percutaneous fixation,

open reduction and internal fixation with conventional or locked-plate fixation, and hemiarthroplasty.

In the future, locked-plates in combination with the use of osteobiologics may play an important role in the treatment of displaced proximal humeral fractures, facilitating preservation of the humeral head in appropriately selected patients[2].

Material and Method

Prospective study during the period March 2015–January 2018 in level 1 trauma center, Twenty three (23) patients underwent treatment of proximal humeral fractures using deltoid splitting approach. Out of these three (3) cases were excluded from the study as they had shoulder hemiarthroplasty (2 cases and one side of bilateral fractured patient), in one of the cases there was intraoperative humeral head split which was not diagnosed preoperatively and so, it was excluded from the study. The study group comprised 11 men and 9 women, with a mean age of 49 years (range 20–77). Patients were followed up for a minimum of one year (12-15 months).

Four cases were pedestrian of road traffic accidents, ten cases were involved in motor car accidents, six cases were due to a fall on the ground. We classify our proximal humeral fractures according to Neer's classification. Out our cases, 9 cases had associated osseous injuries, one patient had lung contusion. All patients who were involved in traffic accidents received a full survey at the time of emergency admission and other associated osseous lesions were managed accordingly.

The surgery was performed after a mean time of 3 days (range 1–5 days). Radiological investigations consisted of AP and axial views performed during the immediate postoperative period and an AP view at follow-up visits. Residual post-operative displacement and late displacement of the fracture were measured by an independent observer. Failure was defined as at least 10 degrees of decrease in humeral shaft angle or by a decrease of humeral head height by > 5 mm compared with immediate post-operative X-ray.

Inclusion Criteria:

1. Age: adults from 20 – 80 years old.
2. Closed fractures.
3. Fractures Neer type II, III and IV.
4. Fracture dislocations.

Exclusion Criteria:

1. Neurovascular affection or diseases.
2. Previous surgery in the affected shoulder.
3. Non fit patients for surgery.
4. Head split fractures (comminuted humeral head fractures).
5. Patients who needed shoulder hemiarthroplasty.

Operative Procedure:

Anaesthesia: General anesthesia was used for all the patients and was combined with scalene block anesthesia in some of the cases for postoperative pain control. Prophylactic broad-spectrum antibiotic, 3rd generation cephalosporin, was given preoperatively within an hour and in all cases.

Patient Positioning: Patient in semi-sitting position. For all of them we should ensure radiolucent area under the shoulder allowing for intra-operative fluoroscopic AP, external rotation and internal rotation views.

Operative Technique: The incision is made from a point between the anterior third and the posterior two thirds of the lateral border of the acromion and can be extended downwards and be completed as the anterolateral approach of the humerus. Marking 5cm below the lateral border of the acromion is made as a landmark which helps for easier identification of axillary nerve intraoperatively, after incising the skin and the subcutaneous tissues with adequate hemostasis the fascia over the deltoid muscle is now visible.

The fascia is now dissected and the anterior raphe of the deltoid muscle is identified as a white raphe between the anterior and middle fibers of the deltoid.

After blunt splitting of the raphe without cutting through any muscle fibers, identification of the axillary nerve is done at about 5-7 cm from the lateral border of the acromion, the nerve is found inside the muscle and sometimes it is more than one branch (leach of nerves) close to each other. Anterior and posterior gentle release of the nerve to free it and gently elevating it, the subdeltoid bursa now is identified and the fracture is reached.

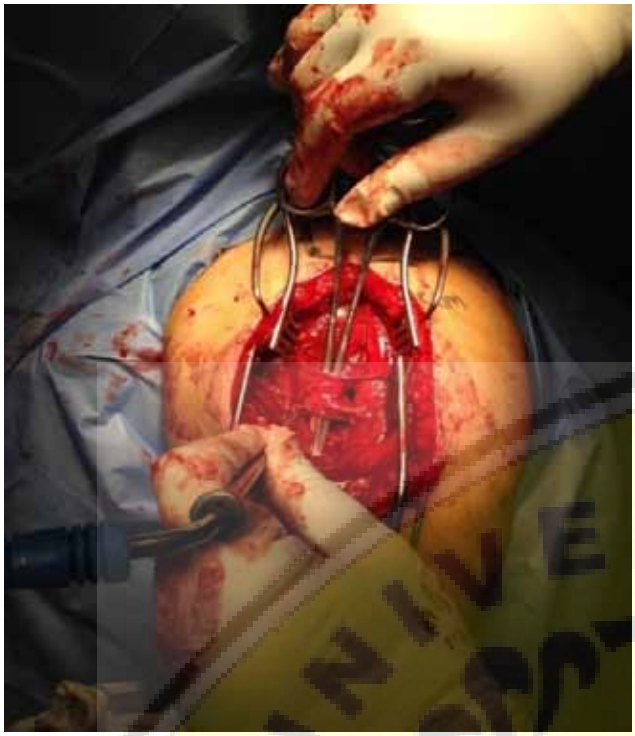

Fig. (1): The axillary nerve and it is seen as a leach of nerves.

The fracture now is identified and reduced either by direct reduction or by indirect reduction by putting conventional screw in the oval hole of the plate after application of the plate under the nerve. In comminuted fractures sutures can be taken in the greater tuberosity or/and the lesser tuberosity and then can be passed through the plate holes after putting the head screws in order not to cut the suture by the progressing screws, Another method of reduction involve preliminary K wires fixation of the fracture through small holes in the philos plate .

Confirm Reduction: Confirm the reduction by image intensification; attention should be paid on the correct alignment of the proximal humerus in all planes. Particularly varusmal position has to be corrected. The medial "calcar" region should be well opposed.

Results

Post-operatively our patients were checked for the condition of the wound, neurology, and distal pulses. Distal pulses were felt in all patients; there were no intraoperative iatrogenic neurologic injuries. Closed suction drains were removed after 2 days in all of our patients; and patients were mobilized from the arm sling as soon as possible most of them on the 3rd postoperative day. Our cases were followed up for a minimum 12 months (range from12 – 15 months), three cases were lost in follow up visits .We used The Constant shoulder score [3]**(Constant and Murley, 1987)**to evaluate the functional outcome and the humeral shaft angle ***(HSA)*** and humeral head height ***(HHH)***to assess theradiological outcome.

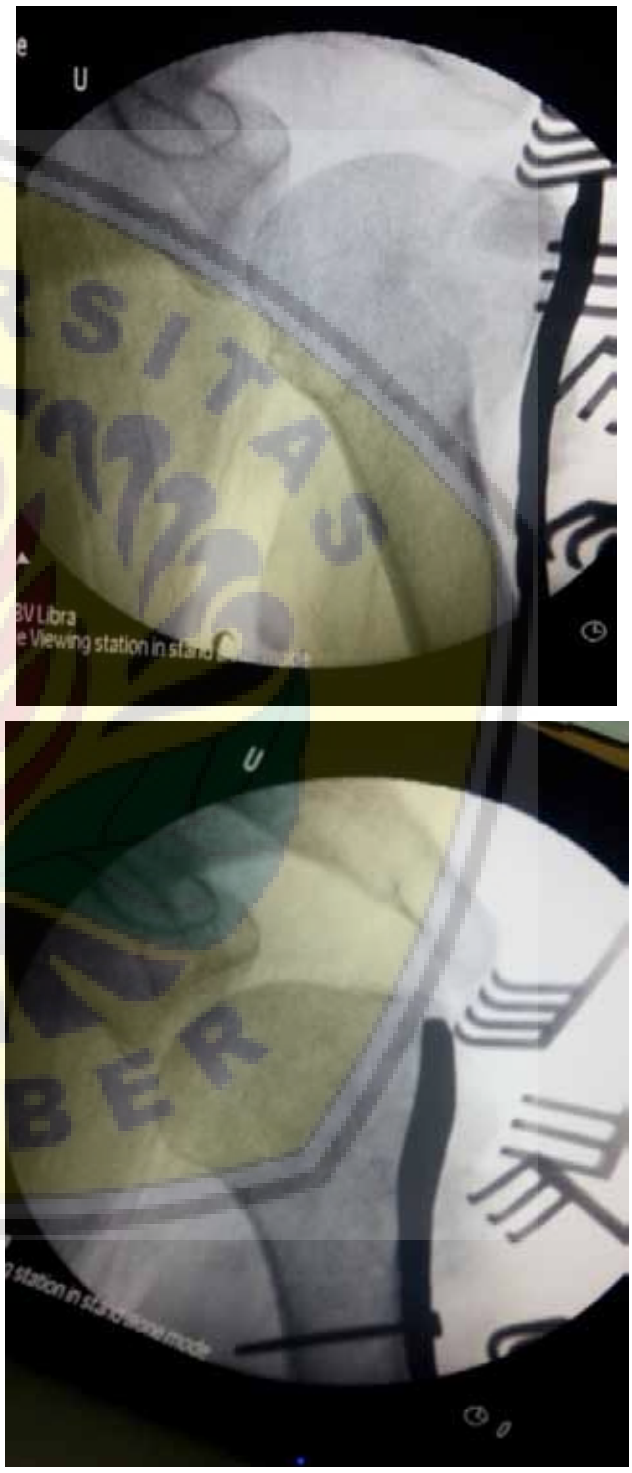

Fig. (2): Indirect reduction after application of the plate by conventional screw in the oval hole of the plate.

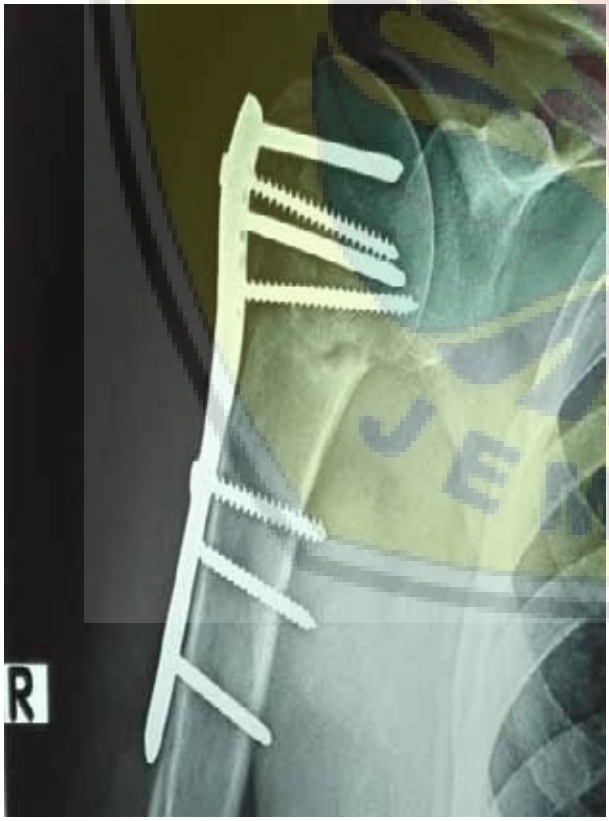

Fig. (3): pictures of two patients in the study after completing fixation by philos plate with the axillary nerve is seen in the first image and accepted position of the plate in the second image.

Scoring of the Results: The Constant shoulder score[3]**(Constant and Murley, 1987)** was used to evaluate the functional outcome of our patients, four factors were assessed and scored; Pain reported by the patient (15 points); Activities of Daily Living (ADL) reported by the patient (20 points); Range of Movement - assessed by the examiner (40 points) and strength - assessed by the examiner (25 points), the greater number of points up to a maximum of 100 points indicates better function of the shoulders.

Complications:

A. **Infection:** Wound problem recorded in 3 patients; all of them had superficial wound infection with serous discharge. This infection was managed by repeated dressing and antibiotic treatment and all of them went to uneventful recovery.

B. **Malreduction and malunion:** In all the cases it was aimed at anatomical reduction, the results of the series showed, each one of them has got good and anatomical reduction but four of them have got poor reduction.

C. **Shoulder stiffness:** In the study 2 cases had shoulder stiffness one month postoperative but there was marked improvement after physiotherapy with no functional impairment.

D. **Neurological complications:** None of the patients in our study had signs of postoperative axillary nerve injury in the form of permanent deltoid wasting or parasthesia at the badge area. Only one case had an axillary nerve partial axonal neuropathy and it improved after seven months.

E. **Cosmetically Bad Scar:** None of the patients in our study complained of scar problems due to the relatively small sized incision which was stitched in all patients either by subcuticular stitching or by staples, although the scar is not parallel to skin Langer's lines.

Discussion

Most authors advocate a deltopectoral approach for the treatment of unstable 3- and 4-part fractures of the proximal humerus; this approach is extensile and allows for easy intraoperative conversion to hemiarthroplasty. However, visualization of the fractured greater tuberosity, which is usually externally rotated by the cuff muscles is difficult and often requires extensive soft-tissue retraction and dissection. Often, the deltoid origin

or insertion and/or the pectoralis major insertion must be at least partially detached to access this fragment. Significant functional impairment of the anterior deltoid can occur with release of >20% of the deltoid insertion.

Florian Fankhauseret al.[4] had a series of 28 patients who had open reduction and internal fixation of proximal humeral fractures by locked plate and screws using the deltopectoral approach. He stated that the overall clinical results, with a mean Constant and Murley score of 74.6 points in patients with an average age of 64.2 years.

Robert A. Gallo et al.[5] had a series of 10 patients who had open reduction and internal fixation by locked plate and screws for fixing proximal humerus fractures using 2 incision technique, the first is a standard deltopectoral incision for placing the shaft screws, the second is a 4-cm lateral incision is marked from the edge of the mid portion of the lateral acromion and extended longitudinally to the posterior aspect of the humeral head for mobilizing a retracted greater tubrosity. The main complication of this 2-incision technique is postoperative stiffness, which affects the treatment of proximal humerus fractures in general.

Gardner et al.[6] reported that no iatrogenic axillary nerve injuries had occurred in 70 cases performed using deltoid splitting approach, and in several cases, the nerve was found to be incarcerated in the fracture and freed before fracture reduction. He found that when splitting the anterior deltoid raphe distally from the acromion, the axillary nerve was found in a predictable location.

LaFlammeet al.[7] used a proximal deltoid split approach for locked plating of 30 proximal humerus fractures, and they noted that the axillary nerve was easily palpated and protected in all cases. Similarly**, Lill et al**. [8] used a deltoid splitting approach, paying close attention to the location and protection of the axillary nerve, and placed locked screws distally. These authors reported no complications related to this approach.

Egolet al.[9] concluded that the relatively low incidence of avascular necrosis may be due to the use of surgical techniques involving less soft-tissue dissection and preservation of vascularity. Care should be taken to avoid the complications of humeral head avascular necrosis while using the deltopectoral approach for treating proximal humeral fractures with a short calcar segment. Less soft-tissue dissection and preservation of vascularity may help to decrease the incidence of avascular necrosis.

In our study we had 20 patients with less than 5 day-old fractures were fixed surgically by locked proximal humeral plate and screws and followed up for a minimum of one year (average, 1.3 years).

It was noted that the axillary nerve was easily palpated and protected in all cases, using a deltoid splitting approach and paying close attention to the location and protection of the axillary nerve then placing locked screws distally gave good results.

There were no adverse effects from exposing the axillary nerve and placing a plate beneath it. However there was one case of partial axillary nerve affection which was fully recovered after seven months with no permanent deltoid atrophy.

The distance between the axillary nerve and the lateral border of the acromion was measured in every case in the study and the average distance was 5.7 cm (from 5.3 cm to 7.2 cm). There were no non unions, no cases of deep infection which required implant removal and no reoperations were done.

There was mal-reduction in 4 cases in this study in the form of head shaft angle (HSA) of <125◦and humeral head height (HHH) < 5 mm varus displacement.

The preoperative delay before surgery and associated fractures in the same limb had poorer results especially in old patients. In our study there was better positioning of the plate and this led to better placement of the head screws and avoidance of impingement with.

The patients with the best results were the patients who had low energy trauma, good bone quality, and intact posteromedial cortex. Even with highly comminuted fractures, this approach is considered an effective alternative to deltopectoral approach. The average time for return to work in isolated proximal humerus fractures in the series was six weeks.

Conclusion

Deltoid splitting approach is a reliable technique for treating acute displaced proximal humeral fractures, which enables patients to use their hands earlier with high satisfaction and minimum complications. Surgery with minimal surgical trauma to soft tissue is considered to be the key to a successful outcome.

Abstract

Introduction: Endoscopic third ventriculostomy (ETV) is gaining popularity as the modality of choice in patients with hydrocephalus of different etiologies. The aim of this study was to review the clinical and radiological outcome of patients with hydrocephalus due to aqueductal stenosis who were operated upon ETV or ventriculoperitoneal (VP) shunting.

Method: A prospective cohort study that included70 patients with AS of different etiologies were studied. Cases were divided into two groups, Group A included patients that were operated upon by ETV and Group B included cases that were operated upon by VP shunt. The selection of procedure was decided based on availability of endoscopic set and surgeon preference.

Results: Our study included 70patients; Group A included 44 cases (62.8%) while Group B included 26 cases (37.2%). Most of cases were presenting with headache, vomiting and papilledema. Imaging showed triventricular hydrocephalus due to aqueductal stenosis. ETV succeeded in 37 (84%) of cases. 26% of Group A patients presented with early complications with 14% failed ETV that required VP shunt. Compared to ETV, Group B had almost no perioperative complications, while late complications as shunt obstruction and/or infection were significant in 34.5% of cases.

Conclusions: In adults with aqueductal stenosis the success rate of ETV may exceed 80%. The delayed complications of shunt system render ETV the modality of choice in aqueductal stenosis. Radiological improvement has no clinical impact in successful ETV cases.

Keywords: *Aqueductal stenosis, Hydrocephalus, Endoscopic third ventriculostomy, Ventriculoperitoneal shunts.*

Introduction

Aqueduct stenosis (AS) is either primary when isolated or secondary to compression by pineal region tumors[1]. Primary AS has no identifiable cause in the majority of cases and known as idiopathic.[2,3,4,5] A study done by Hirsch et al. Included 114 patients were 74% considered idiopathic[6].

Primary AS can take one of different histological types including; atresia, forking, septum or gliosis. [7, 8] Endoscopic third ventriculostomy ETV and shunt surgery are the most commonly used modalities for treatment of AS. While shunt surgery is successful in more than 80% of patients, shunt related complications made recent studies focusing more on ETV.[2, 3, 5, 9].

As regards the perioperative morbidities and mortalities, mortality rate is close to zero in modern studies on shunt surgery. Morbidities are usually due

Corresponding Author:
Mostafa Raafat Motawae
Neurosurgery Department, Faculty of Medicine, Beni-Suef University, Egypt
e-mail: raafatneuro@med.bsu.edu.eg

to long term side effects as infection and mechanical dysfunction.[10, 11] The complication rate in 5 year follow up can reach up to 50%.[12] As the shunt is a lifelong treatment modality, the risk of complications is cumulative with younger patients have higher risk due to longer life expectancy.[13]

ETV success rate is higher in adult population approaching 80%. Limited follow up after ETV can make the evaluation of long-term efficacy difficult.[6, 14, 15]Ventriculostomy occlusion could represent a fatal complication in some cases.[16]While shunt complications are usually delayed, ETV complications are usually early after surgery and usually transient.[4] Still shunt is recommended by most authors as an alternative to failed ETV operations.[6]

Method

A prospective cohort study in which seventy patients with aqueductal stenosis of different etiologies were studied. Cases were divided into two groups. **Group A** included patients that were operated upon by ETV and **Group B** included cases that were operated upon by VP shunt. These cases were brought to clinical attention in Cairo University, Beni Suef University hospitals, over two years starting from October 2015 through October 2017.

Patients included were of adult age group, with different underlying etiology of aqueductal stenosis including pineal region lesions and tectal gliomas, while Patients with history of previous CSF shunt insertion, or CSF infection were excluded from our study.

Preoperatively evaluation was submitted for each patient including a full history, full clinical examination, routine laboratory investigations, CT scan and/or MRI were done. Preoperative ETV success score[17] was recorded for every case. Patients were submitted to either ETV or VP shunt. The selection of procedure was based on availability of the procedure, surgeon preference. In the early postoperative period, the patients were monitored for improvement of the clinical manifestations using Glasgow coma scale (GCS)[18] to assess the conscious level, and visual analogue scale (VAS)[19] to evaluate headache improvement. Patients were followed for 1 month postoperatively to monitor possible early or delayed postoperative complications.

All patients were subjected to control *CT scan* of the brain on the first postoperative day, 1 week postoperative and 1 month postoperative to evaluate the size of ventricles, periventricular CSF permeation, and cortical effacement. Postoperative MRI brain T2 sagittal sequence was done for all Group A patients to detect a patent ostium 1 week after the procedure.

Statistical Method: Data of the seventy patients was coded and entered using the statistical package SPSS (Statistical Package for the Social Sciences) version 25. Data was summarized using mean, standard deviation, median, minimum and maximum for quantitative data, and using frequency (count) and relative frequency (percentage) for categorical data. Comparison between quantitative variables was done using the nonparametric Mann-Whitney test.For comparing categorical data, Chi square test was per-formed. Exact test was used instead when the expected frequency was less than five. P-value < 0.05 was considered as statistically significant.

Results

The data collected from 70 adult cases with Aqueductal stenosis were analyzed prospectively. **Group A** included 44 cases (62.8%) while **Group B** included 26 cases (37.2%).

The distribution of demographic, clinical data and etiology are shown in tables 1, 2.

Table 1: Patients' demographic and clinical data

		Group A	Group B	p value	Significance
Age (Years)		57.48 ± 10.14	58.12 ± 8.52	0.669	NS
Gender	Male	27 (61.4%)	17 (65.4%)	0.737	NS
	Female	17 (38.6%)	9 (34.6%)		
Headache	VAS more than 5	36 (81.8%)	24 (92.3%)	0.303	NS
	VAS less than 5	8 (18.2%)	2 (7.7%)		

		Group A	Group B	p value	Significance
Vomiting	Yes	26 (59.1%)	10 (38.5%)	0.095	NS
	No	18 (40.9%)	16 (61.5%)		
Papilledema	Yes	16 (36.4%)	7 (26.9%)	0.416	NS
	No	28 (63.6%)	19 (73.1%)		
Abducens palsy	Yes	4 (9%)	5 (19.2%)	0.783	NS
	No	40 (91%)	21 (80.8%)		
Gait Disturbances	Yes	3 (6.8%)	2 (7.6%)	0.541	NS
	No	41 (93.2%)	24 (92.4%)		
Disturbed conscious level (GCS)	Yes	15 (34.1%)	11 (42.3%)	0.492	NS
	No	29 (65.9%)	15 (57.7%)		

NS (non-significant), GCS (Glasgow Coma Scale), VAS (Visual Analogue Scale)

Table 2: Etiology of Aqueductal stenosis

	Group A	Group B	p value	Significance
Pineal Region lesion (2ry)	20 (45.5%)	11 (42.3%)	0.480	NS
Idiopathic (1ry)	24 (54.4%)	15 (57.7%)		

NS (non-significant).

Clinical Outcome: Regarding the clinical outcome in both groups, conscious level assessment by Glasgow coma scale (GCS) showed improvement in both groups with no statistically significant difference (p value 0.645).Postoperative assessment of headache severityusing VAS on day 1 postoperative showed no statistically significant difference between the 2 groups (p value 0.516).

Utilizing the ETV success score, all the cases included in Group A have scored 90 points. The ETV success rate was 84% (37 cases), while 16% (7 cases) had persistent symptoms in the early postoperative period and required VP shunt.

Postoperative complications were monitored in the early postoperative period (1 week) and the late postoperative period (1 month) as in table 3 and 4 respectively.

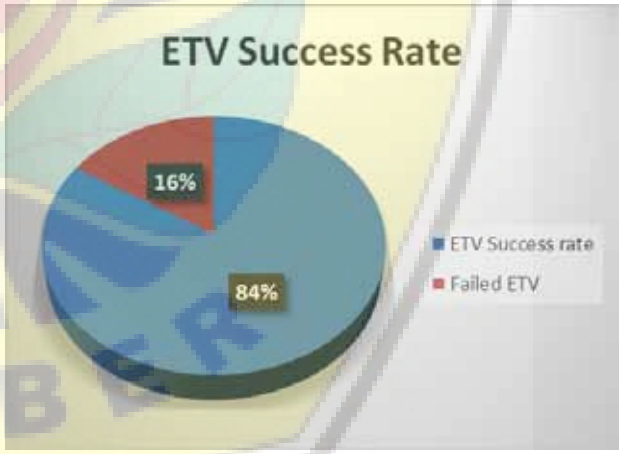

Figure (1): ETV Success rate.

Table 3: Early Postoperative complications

Complications	Group A (%)	Group B (%)	P value	Significance
Failure	7 (16)	0 (0.0)	0.001	S
Fever	12 (27)	3 (11.5)	0.001	S
Vomiting	3 (6.8)	2 (7.6)	0.654	NS
CSF leak	2 (4.5)	0 (0.0)	0.145	NS
Fits	2 (4.5)	0 (0.0)	0.145	NS

S (significant), NS (Non-significant).

Table 4: Delayed Postoperative complications:

Complications	Group A (%)	Group B (%)	P value	Significance
Failure	0 (0.0)	9 (34.5)	0.001	S
CSF Infection	0 (0.0)	3 (11.5)	0.001	S
Dysfunction	0 (0.0)	6 (23)	0.001	S

S (significant), NS (Non-significant).

The radiological outcome was evaluated on basis of reduction of the ventricular size and/or periventricular CSF permeation in CT scan done on day one (early) and 1 month(late) postoperative as in table 5. Early radiological improvement was found in almost all cases of group B, while in group A delayed or no radiological improvement after 1 month which had no clinical correlation.

Table 5: Radiological outcome

	Duration	Group A(%)	Group B(%)	p value	Significance
Lateral Ventricle size	Early	2 (4.5)	26 (100)	0.001	S
	Late	12 (27.3)	0 (0.0)		
3rd Ventricle size	Early	8 (18.2)	24 (92.3)	0.001	S
	Late	30 (68.2)	2 (7.6)		
CSF permeation	Early	34 (77.3)	24 (92.3)	0.564	NS
	Late	8 (18.2)	2 (7.6)		

S (significant), NS (non-significant)

Discussion

The population selected for our study were 70 patients with age ranged from 16-55 and mean age of 31 years. Few other studies were concerned with adult age group with aqueductal stenosis as **Grand** study of 250 adult patients, age ranged from 17 to 88 years with mean age 51 years.[20]. **Tiesell** has reported age ranging from 16-75 with mean age of 30 years.[21]

In our study, aqueductal stenosis was 1ry in 39 (55.7%) of cases and 2ry to pineal or tectal tumors in 31 (44.3%) of cases. In the literature, most of the studies were concerned with 1ry aqueductal stenosis in adult age group. Our results denoted that tumoral stenosis is a common etiology in contrast to results of **Hirsch et al** Study of 113 patients with aqueductal stenosis; tumoral stenosis was detected only in 24% of patients.[6]

Other studies were concerned with tumoral obstructive hydrocephalus as that of **Anthony et al**, in thier study of 117 patients with hydrocephalus due to infratentorial tumors revealed that 40% of patients had aqueductal stenosis due to tumoral obstruction. [22]

In our study, the most common clinical findings were headache (85.7%), vomiting (51.4%), papilledema in (32.8%). Less frequent symptoms as urinary incontinence, gait disturbances and cranial nerve affection were also reported. **Tiesell** has publishedthe analysis of data collected from nine studies concerned with aqueductal stenosis in adult group. Headache was the most common symptom as in our study, with median frequency of 70%. Vomiting and papilledema were the 2nd common with median frequency of 40% and Papilledema 30%.[21]

In our study, analysis of the preoperative radiological findings for all cases was done. Results revealed that all caseshad clear triventricular hydrocephalus with cortical effacement. Our result were corresponding to

the results that **Stoquart**has reported in his 17 cases study concerned with diagnosis of aqueductal stenosis by means of MRI, that all cases had triventricular hydrocephalus with small 4th ventricle.[23] Results were also close to results of **Tushar and Falconer** study of 10 cases in which all cases had the same radiological features, but moreover they reported that only half of the cases had funneling of the aqueduct.[24]

There are 2 major alternatives for treatment of cases with aqueductal stenosis, ETV and shunting. In our study, 44 cases (62.8%) were submitted to ETV while 26 cases (37.2%) were submitted to V/P shunts. Almost all modern studies on aqueductal stenosis are more focused on ETV than shunting.

In our study, all cases have scored 90 in Drake ETV success score. The success rate of ETV cases was 84%, while the success rate of V/P shunting was 100%. **Grand** has reported a success rate of 76% in his 250 adult patients submitted to ETV.[20] **Labidi** study of 59 adult patients with aqueductal stenosis submitted to ETV revealed that success rate was 82%, which is close to our results.[25]

In our study, variable intervals follow up CT scans were made for each case revealing early reduction in size of third ventricle within the 1st month post-operative, while lateral ventricle size reduction started with variable degrees within 6 months postoperatively. Delayed reduction in the ventricular size in ETV had no clinical significance in all cases, as it didn't change the outcome .Other studies have reported the change in ventricular size in variable postoperative intervals following ETV.

Romeo et al have reported in their study that Persistent ventriculomegaly has been noted even in the absence of clinical symptoms of hydrocephalus, prominent reduction in size of ventricles in the 1st month postoperative but he didn't report any cases of normalized ventricular size, as in our study.[26]**Tiesell.** had a different conclusion that reduction in the size of ventricles is a sign of ETV success and is directly related to clinical improvement.[21]

Perioperative complications are more common with ETV than shunting. **In our study**, no intraoperative complications were reported. While in the early post-operative period Fever was reported in 12 cases (27%), fits in two case (4.5%), and CSF leak in two cases (4.5%). Late complications were more common with V/P shunts as shunt obstruction or shunt infection. **Labidi** study, they reported fits in 10% of cases, CSF leak in 10% of cases,motor deficit was reported in 2% of cases, and significant ICH in 2% of cases.[25]

Conclusion

In adults with aqueductal stenosis the success rate of ETV may exceed 80%. The delayed complications of shunt system render ETV the modality of choice in adult patients with aqueductal stenosis. Delayed radiological improvement in successful ETV cases has no clinical impact.

Factors Affecting Prevention of Joint Contracture Regarding Patients with Burn

Nadia Mohamed Taha[1], Eman Ali Metwaly[2], Samah Abdallah Mohamed[2]

[1]Professor, [2]Lecturer, Medical–Surgical Nursing Department, Faculty of Nursing, Zagazig University, Egypt

Abstract

The prime objective of this study was to assess the factors affecting prevention of joint contracture in Egyptian burn patients. About 30% of patients under study were females; males respectively; 61.8% of them were married. Also 80% of studied patients are living in rural areas. The studied patients had unsatisfactory levels of both knowledge and practice regarding prevention of joint contracture. It was showed herein that Physical factors as complications at site of burn as infection, minimal physical exercise, minimal joint support, minimal skin graft, and no regular physiotherapy, Psychological factors as Fear from pain associated with physiotherapy, Fear from occurrence of deformity, and feeling by depression from shape of burn are the important factors needed to decrease burns among Egyptian patients. There was a statistical significant relation between unsatisfactory level of patient knowledge and age (p=0.008), level of education (p=0.022) and occupation (p=0.016). A statistical significant relation between unsatisfactory knowledge and satisfactory level of practice regarding when someone exposed to burn (p=0.016). Also, there was a statistical significant relation between unsatisfactory level of practice and knowledge regarding Skin layers (p=0.024), Outer layers of skin (p=0.006) and Inner layer of skin (p=0.006) and sign of infection (p=0.026).

Keywords: *Joint Contracture, Physiotherapy, Burn, Factors.*

Introduction

Removing deep partial or full-thickness burns without care can develop severe deformity and scar contracture in the joint with significant reduction in patient activities and acute bacterial infection[1,2]. Burns Treatment strategy is prevention of contractures rather than their management. Despite the advances in burn management protocols, there are many data supporting high incidence of joints contractures[3].

The management of joint contractures provides a great challenge both for the orthopaedic and the plastic surgeons[4]. The treatment of joint contractures needs Splinting, movement, physiotherapy, and various surgical method; including scar release, tendon lengthening and osteotomies with skin graft, with almost protracted morbidity in most of the cases[5].

Early excision and grafting of deep second degree and full-thickness burns greatly decrease severity of contractures and hypertrophic scarring. The performed anti-deformity positioning also assist's to avert the risk of contracture formation[6]. All these factors lead to otherwise avoidable contractures. It is currently showed that a burn victim who receives the best initial treatment can expect to heal without any contracture[7].

Stretching, active movement, or passive movement therapy, have historically been an integral part of the physiotherapy management of patients with joint contractures. Both stretches and passive movement therapy recently are the main physiotherapeutic interventions to treat contracture. These interventions can assist in the management of pain and improve burn treatment[8,9]. The general guide- line is that these interventions should start as early as possible to prevent joint contracture.[10]

Research Questions: Assess patients' knowledge regarding prevention of joint contracture. Determined practice regarding prevention of joint contracture. Determined factors affecting prevention of joint contracture regarding patients with burn.

Design: A descriptive design was utilized to achieve the aim of this study and to answer the research question.

Sample: The study sample included purposive sample of patients with 2nd or 3th degree of joint burn in departments of specialized central hospital in Hehya. Total number of sample was 55 patients. Patients with severe co-morbidity diseases as Rheumatoid arthritis were excluded.

Tools:

1. Assessment of patient's knowledge and practice.
2. Factors affecting prevention of joint contracture questionnaire: it includes factors related to burn, physiological factors, psychological factors and social factors.
   - Validity of the tool was done by five expertise and reliability byCronbach's Alpha test and retest was 0.801.
   - Pilot study was done on six patients.

Results

The demographic characteristics of patients under study were recorded. Results are given in Table 1. According to age rang, about 14.8%; 58.2% of patients were ≤30 years; >30 years respectively. Regarding gender about 70.9%; 29.1% of patients were male; females respectively. For the marital status, 38.2%; 61.8% of patients were singles; married respectively. About 74.5%; 25.5% of patients were educated; non-educated respectively. For the occupation, 52.7%; 47.3% of patients were working; not working respectively. In regard to patient residency, about 80%; 20% were rural; urban respectively.

Table 2: Illustrated that the studied patients had satisfactory level of self report practice regarding eating high protein diet, hemoglobin analysis, liver and kidney function**,** regular dressing of burn, maintain fluid and electrolyte equilibrium and decrease pain and edema (81.8%, 81.8%, 78.2%, 76.4%, 65.5%).

The frequency of physiological factors related to site, causes and place of burn were studied. Results are given in Table 3. For site burn, cervical joint was showed by 29.1%, but both lower limbs and limbs were showed by 1.8% for each. Percentage of burns in other sites varied. The causes of burns were flame (49.1%), boiled water (43.6%) and electrical current (7.3%). about (80%) of burns were happened at home, but others at either work (10.9%) or street (9.1%).

As given in Table 4: about 100% of studied patients had joint burn; 58.2% of them had Complications at site of burn, 65.5% of them moving burned area, 78.2% were with regular dressing of burn, 81.8 Eat high protein diet, 81.8% of studied patients moving affected joint incomplete range of motion.

As given in Table 4: about 16.4% of studied patients followed physiotherapy, 14.5% of them followed Physiotherapy in tabulated session. Also, it was found that.

Table (1): Demographic Characteristics of studied patients (n=55)

Demographic Characteristics	Frequency	Percent (%)
Age (Years):		
≤30	23	41.8
>30	32	58.2
Range	16-55	
Mean± SD	32.9±9.4	
Median	33	
Gender		
• Male	39	70.9
• Female	16	29.1
Marital status:		
• Single	21	38.2
• Married	34	61.8
Education:		
• Educated	41	74.5
• Not educated	14	25.5
Occupation:		
• Working	29	52.7
• Not working	26	47.3
Residence:		
• Rural	44	80.0
• Urban	11	20.0

98.2% of studied patients were Fear from deformity, 83.6% of studied patients Fear from not healing of wound and 81.8% of them feel depressed from shape of burn. Also it was illustrated that Social factors affecting burn were as follows: 67.3% of the studied patients Feel isolation due to burn.

As given in Table 6: it was showed that there was a statistical significant relation between total knowledge, and psychological factors of studied patient regarding Fear from pain associated with physiotherapy (p=0.02) and Fear from unhealing of wound (p=0.007).

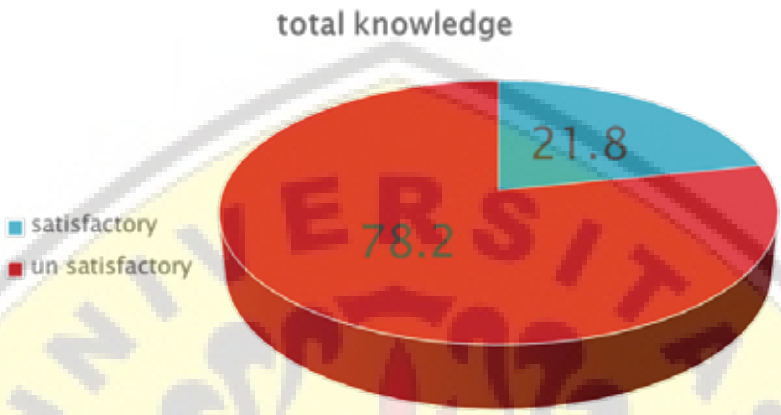

Figure 1: Frequency distribution and percentage of correct patient's knowledge about burn

Discussion

The study population included 55 patients with joint burn in inpatient in specialized central hospital in Hehya Sharkia governorate, Egypt, Nearly more than two thirds of studied patients were male and their age ranged from 18-55 with mean 32.9±9.4. This result may be explained from the researcher point of view by the fact that males are generally active and, therefore, they are exposed to hazardous situations at both home and work. These results supported latter published results in this respect with[11], the ages of patients ranged from 7 to 46 years. In the same line with latter findings[12].

The present study revealed that nearly the majority of patients had unsatisfactory level of knowledge regarding prevention of joint contracture**.** This may be due to lack of community based education related to burn injury. This is coupled with[13] who stated that first aid knowledge for burns is rather limited especially developing and underdeveloped countries. In the same line with[14] who indicated that previous background knowledge on burn first aid was present in more than one third in respondents.

In the study employed herein, nearly more than two third of the studied patients had unsatisfactory level of practice regarding prevention of joint contracture. This could be due to less encouragement of students to conduct health education for burn prevention and first aid management. Also media not develop programs for burn awareness to increase the people knowledge regarding the importance of physical exercise, range of motion and healthy diet. This is in conform with[15] who reported that only one third of total participants were aware of first aid procedures for burns injury management.

Concerning the type of burn injury, the findings of the present study showed that the common causes of burn about half of studied patients is flame followed by boiled water. From the researcher point of view this may be explained that kerosene and gas are the most frequent fuels in houses and work places and carless handling of gas pipes without safety features and accidental hand grenades and firing. This is in agreement with[16].

The present study stated that about one third of studied patients had cervical joint burn followed by knee joint, elbow joint, and wrist joint. This agrees with[12,17]who clarified that among the body areas affected, the commonest contracture was of the neck, followed by axilla, fingers/hand, elbow, knee and ankle/foot, and more than one third of studied patients had more than one contracture.

It was showed in this study that more than half of the burn patients were suffering from mainly infection, which are local and systemic signs as fever, purulent exudates and bad odor. This could be explained by auto infection and from environment contamination which include linen, bed, other patients or visitors and also may be from hospital staff during dealing with patients and open wounds, could not use aseptic techniques observed by researcher during collection of the data.[18,19] within 24h, burned patients can start suffering from opportunistic bacterial attacks that can vary from simple infections, such as those easily treatable by antibiotics to more complicated bacteria, which may have natural or acquired resistance to drugs. Infection by multiple drug resistant bacteria could create additional complexity to the problem.

The most of studied patients were fear from deformity, nearly the majority of them were fear from not healed wound, and about two third of them fear from pain associated with physiotherapy. This could be due to that all patient admitted to burn unit complaining of severe procedural pain after wound dressing and physiotherapy. As most of the patients have no pain killers before procedures (no regularly scheduled analgesics).

Smeltzer et al.[20]. These authors identified that regular pain relief is essential, in particular prior to all interventions such as change of dressing and exercise; this needs to be given in adequate time to take effect before commencing the procedure.

The current study revealed that more than three quarters of the study patients feel depressed from shape of burn. The results were in agreement with[21] who informed that most of burn patients have experienced a very frightening event leading to their burn injury and that the hospital experience itself can be frightening. Patients and his family may be experiencing feelings of anger, guilt and despair; they may also be having nightmares and flashbacks of the event.

It could be recommended that educational programs should be launched to create mass awareness about prevention of joint contracture regarding patients with burn; Providing a number of trainers to manage nursing care for burn patients during critical cases or rehabilitation after treatment is necessary. Also

the educational programs for patients about first aid management of all types of burns.

Conclusion

It was concluded that the studied patients had both unsatisfactory level of knowledge and practice regarding preventing of joint contracture. The most common factors that affecting burn contracture were physical factors, Psychological factors, social factors.

Abstract

Background and objective: We hypothesized that pie-crusting technique does not affect the long term results after arthroscopic partial medial menisectomy.

Method: the study included 30 patients with tight medial compartment who were undergoing arthroscopic partial medial menisectomy.

Results: The follow up period was 3 months. The median Lysholm score had increased at the end of the follow up period to 93 (86-98) with P value < 0.001 which was statistically significant.

Conclusion: The Pie-crusting technique is safe and efficient for visualization of the posterior horn of the medial meniscus. It allows the avoidance of causing iatrogenic chondral damage or fracture of the medial femoral condyle.

Keywords: *Tight, pie-crusting, MCL, medial.*

Introduction

Posterior horn of medial meniscus is commonly a site of meniscal tears. Unrestricted arthroscopic visualization of the posterior horn of medial meniscus is crucial to perform adequate menisectomy. In patients with tight knees, the medial femoral condyle makes the visualization of the posterior horn of the medial meniscus and usage of instruments is very difficult.[1,2].

Vigorous manipulations with the instruments in cases with tight knees may cause iatrogenic chondral damage which may contribute to degeneration of the articular cartilage and osteoarthritis[3,4]. Also this inadequate visualization may lead to insufficient menisectomy[5,)]. Meniscal pathologies may be missed as a result of this inadequate visualization. Moreover this vigorous manipulation to open the medial compartment, could lead to rupture of medial collateral ligament (MCL) or even fracture of femur[7,8].

Agneskirchner and Lobenhoffer[3,9], Bosch[10], Park et al[(11)] and later Fakioglu et al[(12)] revealed a less invasive technique for openining medial compartment by puncturing thpostero-medial capsulo-ligamentous structures percutaneously with the use of a needle.

In the current study, the technique of Fakiogluet al[12] for enlargement of medial joint space in tight knees was used using needles. Also we were concerned about studying the possible complications especially residual medial laxity.

Patients and Method

From February 2014 to October 2015, a prospective

Corresponding Author:

e-mail: dr.mohamrgamal@gmail.com

randomized analytical clinical study was done to evaluate percutaneous release effects of superficial medial collateral ligament (pie-crusting technique) with tight medial compartment of the knee undergoing partial menisectomy for torn posterior horn of the medial meniscus.

The material of this study included thirty (30) patients with torn posterior horn of medial meniscus with tight medial compartment of the knee. All patients were selected according the following criteria:-

- Age: skeletally mature patients.
- Both sexes were included.
- Torn posterior horn.
- Athletes and non- athletes.
- No malalignment that needs corrective osteotomy.
- No other ligamentous injuries.
- No osteoarthritis.
- No any other articular lesions.

Patients were subjected to the following:

(A) Preoperative evaluation

1. Careful history taking: Gender, affected side and cause of injury.
2. Analysis of patient's complaint: Analysis of patient's complaint was carried according to Lysholm score evaluation.
3. Clinical examination: Full clinical examination of the affected knee and the contra-lateral knee was done.
4. Radiographic evaluation:
   - **A. Standard standing X- rays of both knee (AP, lateral views):** To exclude osteoarthritis or malalingment.
   - **B. MRI of the affected knee:** To detect the site & type of the meniscal tear and to detect any other ligamentous injuries or patellar instability.

(B) Operative meniscal procedure after pie-crusting technique: Patients who were planned to undergo partial menisectomy of the posterior horn of the medial meniscus, if they were found to have tight medial compartment, then percutaneous release of the medial collateral ligament was done.

Technique of surgery:

1. **Position of the patient:** The patient was laid supine. A tourniquet over soft cotton is applied and elevated to 300 mm Hg after administration of the anesthesia.
2. **Anesthesia:** 22 patients received spinal anesthesia, while the other 8 patients received general anesthesia. Antibiotic was given with induction of anesthesia.
3. **Routine knee arthroscopy:**
   - Standard antero-lateral and low antero-medial portals were used with a 30° viewing scope.
   - A fluid pump was used for inflow through arthroscopic sheath.
   - Next a quick diagnostic knee examination was done starting with supra-patellar pouch, lateral gutter, patello-femoral joint and medial gutter.
   - Next, a probe was inserted through the antero-medial working portal into the medial compartment.
   - With the knee in extension to 30º flexion, valgus and external rotation were applied by an assistant to give best visualization of PHMM.
   - If visualization or instrumentation were difficult, the pie-crusting technique was done (Figure 1).

Figure 1: Tight medial compartment of the knee

4. **Pie-crusting technique:** When visualization or instrumentation of postero-medial meniscus under valgus stress was inadequate, controlled release for postero-medial capsulo-ligamentous structures with the metal inner shaft of the 16 gauge (G) syringe needle was performed.

- The release was done by targeting the posterior third of superficial MCL proximal to medial meniscus.
- Puncture at this site produces a cracking sensation with a resultant opening in the medial compartment of the knee seen on the arthroscopy screen.
- If the opening in the medial compartment was sufficient on the monitor, then the release was aborted .
- If the realese was not sufficient, postero-medial capsulo-ligamentous structures were punctured without removing needle from skin. A more horizontal planewas used, while endeavoring to limit the punctures to the posterior part of the MCL, and the process was continued until the desired amount of opening of the medial compartment of the knee was reached (Figure 2).

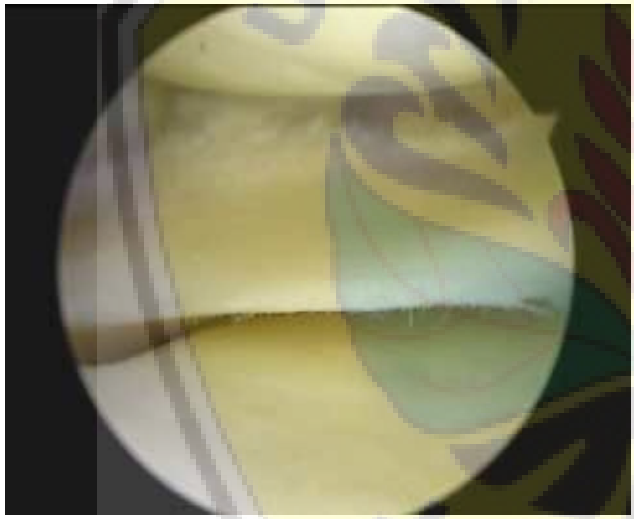

Figure 2: Opening of the medial compartment after pie-Crusting technique.

C. Postoperative care

- The patient was advised to use ice.
- No brace was used.
- Analgesics: Pethidine 50-100 mg ampoule intramuscular was given when required for 2-3 days, Diclofenac sodium 50 mg. tablets twice daily for one week starting from the second day.
- Prophylactic antibiotics: Ceftriaxone 1 gm IV. 12 hourly for 2-3 days.
- Weight bearing was encouraged from the second day post-operative whether with or without crutches as tolerated by the patient.
- Discharging the patient was after 24 hours post-operative.

(C) Rehabilitation program

For the first 6 weeks:

- Active range of motion as tolerated.
- Weight bearing was allowed as tolerated.
- Isometric quadriceps contraction exercises.
- No squatting.
- No pivoting.

After that:

- Squatting is allowed gradually.
- Pivoting is allowed gradually.

(D) Follow up evaluation: All patients were evaluated after surgery every two weeks up to the second postoperative month, then after one month.

In this study the follow up period was 3 months.

After assessment of the patients clinically and radiographically, the postoperative rating scales were recorded and all data were documented 3 months post-operatively.

1. **Clinical Evaluation:** Postoperative clinical evaluation was similar to the preoperative evaluation. In addition the site of pie-crusting was examined for tenderness, swelling or ecchymosis.
2. **Radiological evaluation:** Stress valgus x-rays were done in full extension and 30° flexion after 3 months and the difference with the contralateral normal limb was documented.

These X-rays were examined for: The amount of opening in theMedial joint space (Figure 3-A, 3-B).

3. **Postoperative rating scale:** After clinical and radiographic assessment, the postoperative rating scale was calculated. The Lysholm knee score was used for this purpose.

Statistical Analysis: Comparison of quantitative variables using Wilcoxon signed ranks test was performed for paired samples. . All statistical calculations were done using SPSS version 21. $P< 0.05$

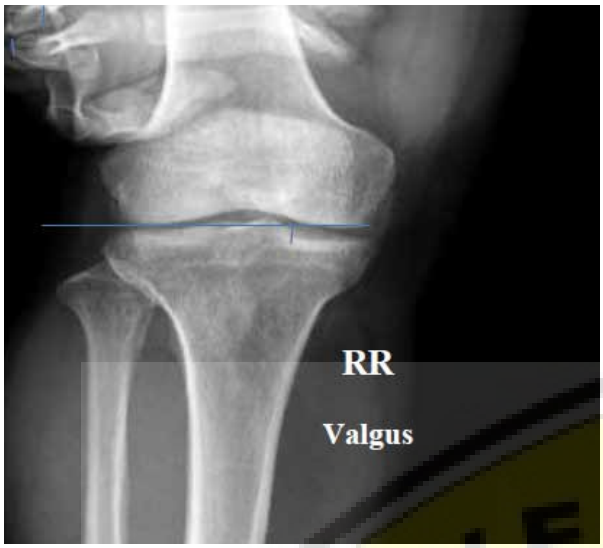

Figure 3A: Stress valgus x-ray in extension.

Figure 3B: Stress valgus x-ray in 30º flexion.

Complications:

1. **Medial sided knee pain:** All of the patients complained of pain at the site of release after the operation that lasted for 1-2 weeks post-operatively and resolved spontaneously.
2. **Residual medial laxity:** No cases complained of post-operative residual medial laxity at the end of follow up period.
3. **Superficial ecchymosis:** 10 patients complained of post-operative ecchymosis that resolved spontaneously

Results

Thirty patients underwent pie crusting technique, while they were having partial menisectomy for torn posterior horn of the medial meniscus. The results of the study at the end of the follow-up period were assessed both clinically and radiologically.

Lysholm Score: Evaluation of patients was done through Lysholm score. In our study the median Lysholm score was about 49 (35-65) in the preoperative period. The median Lysholm score had increased at the end of the follow up period to 93 (86-98) with P value < 0.001 which was statistically significant (Tab. I).

Stress Valgus Test: Regarding the stress valgus test, there was no difference between the normal side and diseased side in extension and in 30º flexion at the end of the follow up period.

Stress valgus x-ray: Regarding the stress valgus x-ray in extension, the mean medial joint space opening was 2.27 mm in the normal side, while it was 2.30 mm in the affected side at the end of the follow up period. The P value is 0.317, which does not represent a statistical significance between the 2 sides.

Regarding the stress valgus x-ray in 30º flexion, the mean medial joint space opening was 3.27 mm in the normal side and in the affected side as well at the end of the follow up period. The P value is 1 which does not represent a statistical significance between the 2 sides.

Tab. I: Compaing between pre/post-operative Lysholm scores

	Mean	Standard Deviation	Median	Minimum	Maximum	P value
Pre-op lysholm score	50.03	8.09	49.00	35.00	65.00	<0.001
Post-op lysholm score	92.47	3.88	93.00	86.00	98.00	

Discussion

The posterior horn of the medial meniscus is still the single greatest source of errors in knee arthroscopy, despite the great advancement in arthroscopic techniques and instruments[1,2].

The superficial MCL is a primary stabilizer of medial side of knee. Biggest strains in the MCL were detected in its posterior region proximal to the joint line according to biomechanical studies[13]

In the current study, pie-crusting was done by puncturing the posterior third of the superficial MCL superior to the meniscus using 16 gauge needle which was moved out-in.

In Fakiogluet al[12] the targeted point for release was also the posterior third of the superficial MCL proximal to the medial meniscus. This was done by the mean of a 16 gauge needle which was out-in. However, they performed postoperative sagittal MRI sections in 14 patients, and they found that the needle punctures were located within the posterior and middle thirds of the MCL, but in four patients, the injury was restricted to the middle third. In all patients, the localization of the injury was proximal to the medial meniscus in coronal sections[12].

Park et al[11] and Atoun E et al[14] performed modified MCL pie-crusting technique and were targeting the posterior part of the MCL just above the joint line by the mean of 18 gauge needle which was moved in-out technique.

In our study, we used manual valgus stress, while Fakiogluet al[12] used an automated device to produce a certain amount of valgus stress force. When visualization or instrumentation of the postero-medial meniscus under this certain amount of valgus stress was inadequate, controlled release of the postero-medial capsulo-ligamentous structures was performed.

In our study, we used Lysholm score as a scoring system. The median Lysholm score preoperatively was 49 (35-65). The median Lysholm score had increased at the end of the follow up period to 93 (86-98) with P value < 0.001 which was statistically significant.

In Fakiogluet al[12], Lysholm score was also used as a scoring system and in our study, we did not encounter any intra-operative complications such as MCL rupture or fracture of the MFC. Although all the patients have post-operative pain (grade I MCL sprain) that lasted for 1-2 weeks, they were capable of weight bearing either alone or assisted by crutches. No brace was used.

Fakioglu et al[12] found no intraoperative complications and during postoperative period, noted mild pain at medial needle tract lasting for 15 days and also no pain on palpation. A short-hinged knee brace worn postoperatively for 4 weeks without restriction in joint motion and with full weight-bearing.

Table (II) shows a comparison between this study and other authors who performed MCL pie-crusting.

Table (II): Comparison between this study results and results of other authors addressing the same problem of tight knees

	The present study	**Park et al [11]**	**Fakioglu et al [12]**	**Bosch [10]**	**Atoun et al[14]**
Operation	Medial meniscectomy	Meniscal suturing	Medial meniscectomy	Medial Meniscectomy	Medial meniscectomy
Needle used	16 gauge syringe needle	18 gauge needle	16 gauge venous cannula	16 gauge venous cannula	18 gauge needle
Target area	Posterior part of superficial MCL above level of MM	Posterior part of *deep MCL* above level of MM	Posterior part of superficial MCL above level of MM	Posteromedial capsulo-ligamentous structures above level of MM at the junction between posterior horn and body of MM	Deep MCL above MM
Needle movement	Out-in	In-out	Out-in	Out-in	In-out
Post-operative radiological follow up	Stress valgus x-ray	No	Stress valgus x-ray and MRI	No	No

Conclusion

Adequate visualization of the posterior horn of the medial meniscus is crucial for the performance of proper menisectomy.

In cases with tight knees, the Pie-crusting technique is safe and efficient for visualization of the posterior horn of the medial meniscus. It allows the avoidance of causing iatrogenic chondral damage or fracture of the medial femoral condyle.

The medial collateral ligament heals eventually in all patients after the Pie-crusting technique without causing any subjective instability.

Incidence of Postoperative Neurological Complications after Off-Pump versus On-Pump Coronary Artery Bypass Surgery in the Early Postoperative Period

Mahmoud Gamaleldin Ali[1], Tamer Farouk Siam[2], Tamer Eid Fouda[3], Ahmed Maher Elnaggar[4]

[1]Ass. Lecturer, [2]Professor, [3]Lecturer, [4]Ass. Professor, Cardiothoracic Surgery Department, Faculty of Medicine, Cairo University, Cairo, Egypt

Abstract

Background: Stroke is a devastating complication of coronary artery bypass grafting (CABG). In our study, postoperative neurological complications were assessed after on pump CABG versus off pump CABG.

Methodology: This prospective retrospective comparative study included 200 patients who had CABG divided equally into two groups: group A (on pump) CABG and group B (off pump CABG). Preoperative, operative and postoperative data are analyzed to compare neurological outcomes of the two groups.

Results: Incidence of early postoperative neurological complications after on pump CABG is higher that after off pump CABG but without statistically significant difference. However, operative time, incidence of AF and ICU stay are significantly more after on pump CABG. While, EF is increased significantly after off pump CABG.

Conclusion: Postoperative neurological insults especially stroke are more after on pump than off pump CABG but that failed to reach statistically significant difference.

Keywords: *Stroke, CABG, On-pump, Off-pump, A.F, ICU.*

Introduction

Neurological injury is an important complication after CABG. It comprises two types. Type-1 includes stroke, transient ischemic attack (TIA) and coma (incidence 3 to 6%). Type-2 is more subtle and includes cognitive impairment. These are defects associated with attention, concentration, memory, motor function and mental responses.

Cardiopulmonary bypass is associated with an intense inflammatory response. This response produces an acute, massive defense reaction, induces mild-to-huge interstitial fluid shifts; generates a host of micro emboli (<500ĕm); and causes temporary dysfunction of nearly every organ.[1]

Method:

Patients: This is prospective retrospective comparative study which includes 200 patients underwent isolated first time CABG, 100 patients by on-pump technique (Group A) and the other 100 patients by off pump technique (Group B) in Cairo University hospitals. Patients were excluded for:

- Combined cardiac surgery.
- Emergency surgery.
- Cardiogenic shock.
- Preoperative intra-aortic balloon pump.

Corresponding Author:

e-mail: dr.mahmoud.gamaleldin@outlook.com

- History of supra-ventricular tachyarrhythmias.
- Renal or respiratory impairment.
- Previous stroke, transient ischemic attack.
- Significant carotid artery lesion.
- Intracardiac masses or thrombi.
- Ascending aortic calcification
- Conversion from off-pump to on-pump technique

Peri-operative data were collected for each patient in both groups.

Postoperative Neurological examination: The first post-operative neurological examination was performed in ICU 12 hours after admission. Functions were checked and compared with preoperative status. Pupillary reflex, orientation, speech, memory, motor and sensory function. The major outcome variable was stroke which is defined as visible/evident temporary or permanent new neurological defect during the same hospital stay. The neurological deficit was confirmed clinically by a senior neurologist unaware of the study status and CT brain scan in case of positive examination.

Results

Table (1) illustrates proper matching between both groups.

Table (1): Demographic characters in study groups

Variables	On pump CABG (n=100)		Off pump CABG (n=100)		p-value	Sig.
Age (Years)						
Mean/SD	56.1	8.1	56.9	8.6	0.5	NS
Sex						
Male	85	85%	70	70%	0.02	NS
Female	15	15%	30	30%		

Table (2) illustrates that there is no statistically significant difference between two study groups as regards medical history. On the other hand, there is statistically significant difference with p-value <0.05 as regards smoking history with **higher** percentage of smokers were found among group on pump CABG.

Table (2): Comparisons of medical history in different study groups

Variables	On pump CABG (n=100)		Off pump CABG (n=100)		p-value	Sig.

Discussion

Neurological injury resulting from cardiac surgery has a range of manifestations from focal neurological deficit to encephalopathy or coma[2]

In our study, we tried to answer this question "Is incidence of stroke and other neurological complications reduced after off-pump CABG versus conventional on-pump CABG or not?" By analyzing our experience with both techniques.

Analysis of the preoperative patients' criteria showed that the mean age in group A was 56.1 year and in Group B was 56.9 with no significant difference between both groups. This was found to be generally younger than CABG population in western cultures. **In 2007, Biancari** and others reported that the mean age was 66.2 ± 9.1 year in CCAB group and 65.9 ± 8.8 in OPCAB group. [3]

We also found that males represent 85% and females 15% in group A while in group B, males represent 70% and females make 30% of the whole group with no significant difference between the two groups. In **2010**, **Maas AH and Appelman YE** explained that CAD is less common in females as Cardiovascular disease develops 7 to 10 years later in women than in men and they assumed that exposure to endogenous oestrogens during the fertile period of life delays the manifestation of atherosclerotic disease in women.[4]

According to Hogue et al, in 1999, History of stroke is the strongest independent predictor of perioperative stroke. As a result, we excluded any patient with history of any neurological deficits.[5]

We also excluded any patient with carotid artery lesions in both groups by performing routine preoperative bilateral carotid artery duplex.In **Da Costa'sseries in 2015**, there was a 10% rate of ischemic stroke in patients with carotid stenosis ≥50%, and in carotid stenosis ≥ 70% this index reaches about 16.6 %.[6]

Palmerini and othersin2014, stated that chronic AF is a risk factor for cerebral embolism, and in patients undergoing CABG the peri-operative period may be at increased risk of stroke due to the necessity to modulate anticoagulant therapy. That's why we excluded patients with AF from to avoid misleading results.[7]

In our study, the mean preoperative EF in group A was 57.02 while it was 57.7 in group B with no significant difference between both groups. Patients with poor contractility are excluded from this study as according to **D'Ancona et al**, depressed LVEF% (<30%) is a stronge preoperative determinant for Cerebrovascular accidents. [8]

Severe atherosclerosis of the ascending aorta is often an unexpected intra-operative finding during CABG **(Palmerini)**. So intraoperative gross assessment of the ascending aorta for aortic wall astherosclerosis and calcifications was performed routinely for all patients in this study to exclude patients with aortic asthersclerosis.[7]

Regarding the average number of proximal anastomoses to the ascending aorta, the mean number in group A was 1.9 while it was 1.8 in group B with no significant difference between both groups. This means that manipulations of the ascending aorta in both techniques were comparable. Unlike this study, **Biancari's study in 2007** stated that he number of proximal aortic anastomoses in OPCAB group was 1.6 ± 0.7 significantly less than 2.1 ± 0.6 in the CCAB group which may be explained by decreased number of distal anastomoses in **Biancari's study** which is not the case in our study.[9]

In this study, the mean cross clamp time in group A was 52.02 min and the mean CPB time was 66.8 min. In **2003, Ancona's analysis** concluded that even myocardial ischemic time longer than 90 min and CPB longer than 120 min did not have a significant impact on CVA rate **(10).Ancona's** results are in contrast with the findings of **Bucerius *et al.* in 2003** where CPB time had a strong independent relationship with CVA occurrence.[11]

Analysis of the postoperative results in this study shows that more patients in group A (7 patients) had re-exploration for bleeding than group B (3 patients) but with no significant difference. **Frojd and Jeppsson in 2016** stated that re-exploration for bleeding was a significant predictor of perioperative stroke.[12]

In our study, incidence of postoperative AF was 19% in group A higher than that of group B 8% and it was statistically significant. On the same way, **Moller's met-analysis in 2008** showed a significantly reduced risk of AF in OPCAB group as compared with CCABG group [13]. However **Ercan's study** stated that there is no difference in the incidence of post-CABG AF between OPCAB and CCAB groups[14]. **Palmerini and others in 2014** suggested that new onset AF is also a risk factor for post-CABG stroke.[7]

Postoperative neurological examination in our study showed that incidence of postoperative major neurological complications in group A was 5% higher than that in group B (2%) but without significant difference. In group A "on pump CABG", 5 patients had cerebrovascular accidents in the early postoperative period with one mortality and 2 patients in group B with no mortality as detailed before in table[7].

In **Biancari's study in 2007**, Off-pump CABG was

performed in 557 patients, and conventional CABG was performed in 445 patients. Off-pump CABG was associated with a lower but not significant rate of postoperative stroke i (1.8% vs 2.5%, P = .45). **Biancari** concluded that the neuroprotective efficacy of OPCAB is marginal compared with that of CCABG[9]. Moreover, **Ascione's study in 2002** which included more than 4000 patient who had isolated CABG, 22% of them had off-pump technique demonstrated that off-pump surgery was associated with a substantial, but not significant, protective effect against stroke [15].

On the other hand, a Meta-Analysis of Systematically Reviewed Trials (3996 patients enrolled in 41 RCTs) made by **Sedrakyan and colleagues in 2006** illustrated that Off-pump CABG was associated with a 50% reduction in the relative risk of stroke, 30% reduction in AF and 48% reduction in wound infection. Stroke was reported in 27 trials and evaluated in 3062 patients. Off-pump use was associated with fewer strokes in most of individual trials. They explained that by one of the most important predictors of stroke after cardiac surgery is manipulation of the atherosclerotic ascending aorta. Off-pump surgery has a potential to reduce the need for aortic manipulation and there is evidence that off-pump CABG is associated with substantially reduced levels of S-100 protein (indicative of minor or major brain injury) and reduced microembolic release as compared with on-pump CABG. They found also substantial reduction in AF associated with off-pump. AF is associated with a higher risk of cerebrovascular accidents, and preventing it was found to reduce postoperative stroke occurrence [16]. Similarly, **Ercan and others in 2014** (a retrospective analysis of 478 consecutive low risk patients undergoing coronary bypass surgery between January 2002 and December 2007) was performed. of these patients, 83 cases had on-pump and 395 cases had off-pump CABG) detected significantly more neurological complications in the on-pump group (1.1% vs. 6% p=0.01). Accordingly even in low-risk patients CPB causes more neurological complications than OPCAB.[14]

Our study has some limitations: limited number of patients in both groups with its disadvantages regarding statistical significance. Also, short follow-up duration is a limiting factor. Other studies with larger number of patients and longer follow-up period may give more conclusive results.

Biochemical and Physiological Study of the Effect of Sesame Seeds on Quail Males Exposed to Thermal Stress

Thaer M. Al-Mushhadani[1], Haitham L. Al-Hayali[1]

[1]Lecturer, Biology Dept./College of Science, Mosul University

Abstract

The research was undertaken to investigate the effect of sesame seeds on quail birds exposed to heat stress through some haematological and biochemical parameters. The results indicate that heat stress caused a significant decrease in haematological parameters. A significant increase in cholesterol, triglycerides, HDL, VLDL, LDH, ALP, AST, ALT, protein, albumin and a significant decrease in LDL in serum. A significant increase in cholesterol, triglyceride, LDH, ALT and albumin in liver. A significant increase in cholesterol, triglycerides, LDH, and AST in heart.

Whereas sesame given a protective effect against the negative impact of heatby raising the level of blood variables tolevel close to what they are in the control group. Sesame also gave a significantly positive effect by reducing some variables such as cholesterol, triglycerides, LDL, VLDL as well as LDH, ALP, AST and ALT enzymesin addition to lowering total protein, albumin and raising the HDL in serum compared with the heat stress group. Sesame also decreased some biochemical parameters in both the liver and heart tissues.

Keyword: *Quail, sesame, heat stress.*

Introduction

Sesame have been widely employed in culinary as well as in traditional medicines for their nutritive, preventive and curative properties. Sesame is a primary source of phytonutrients such as omega-6 fatty acids, flavonoid phenolic anti-oxidants, vitamins, and dietary fiber with potential anti-cancer as well as health promoting properties. Sesame contain up to 55% oil and 20% protein, sesame proteins consisted of lysine, tryptophan and methionine while sesame oil is rich in linoleic and oleic acids[1].

In addition, it content tocopherol and fat-soluble lignans have identified as the major antioxidants of sesame seeds and oil[2].

Heat stress is one of the major causes that results in production losses in terms of decreases in weight gain, feed intake, feed efficiency, and increased mortality. Heat stress considered as a major distress in poultry especially in the hot regions of the world. This may be associated with biochemical and pathological consequences, which can potentially promote the process of oxidative stress[3].

Oxidative stress is one of the consequences of heat stress resulting in increased reactive oxygen species production (ROS), decrease serum and tissue levels of antioxidant vitamins in birds that play a role in the antioxidants defense system, oxidative stress occurs from excess ROS production, antioxidant depletion or both [4].

Breeding of quail has rapidly increased in the last years, quails enter a competition with the broilers as a source of meat as the demand for animal protein has increased therefore the heat stress considered as a major factor of problems for these birds and is enough to cause increased body temperature also change circulating leucocyte components [5].

This study aimed to evaluate the effect of heat stress on quails then observe the effect of administration of sesame on hematological parameters and some biochemical variables especially those related to liver and heart functions.

Materials and Method

Plant: The plant used is sesame seeds (*Sesamumindicum*) placed in empty capsules where each one contain 200 mg (1g/kg body weight).

Animals: Twenty healthy quail males aged (30-35) days and weighted (190-200) g was used. The birds kept in well-ventilated room at controlled temperature (24 ± 2) and eaten standard provender.

Thermal Stress: The thermal stress was done by placing the birds in the room (2x2) m^2 width and 2 m high with upper air vent. Electric heater used as a heat source, the temperature was set at 40 C° and measured by mercury thermometer.

Experimental Design: The birds divided into four groups (5 quail each). The treatment continued daily for 30 days period. The first group (control) given empty capsules (placebo). The second given orally, Sesame capsules daily for 30 days. The third group exposed to thermal stress for 8 hours daily for 30 days. The fourth group exposed to thermal stress for 8 hours and given directly oral seeds capsules daily for 30 days.

Blood Collection: Blood samples were collected from the bird wing vein at the end of the experiment then divided into two parts, one of them with (EDTA) used forcomplete blood count (CBC) and the other part was used for further biochemical analysis.

Hematological Parameters: Packed cell volume (PCV), hemoglobin (Hb), red blood cell count (RBCs), mean cell volume (MCV), mean cell hemoglobin (MCH), mean cell hemoglobin concentration (MCHC), total leucocyte count (TLC) and differential leukocyte count were assessed.

Blood Biochemical Parameters: Serum samples were analyzed for enzymatic activities of aspartate amino transferase (AST), alanine transaminase (ALT), alkaline phosphatase (ALP), lactate dehydrogenase (LDH), total cholesterol (TC), triglycerides (TG), total proteins (TP), albumin (Alb) and globulin (Glob).

Tissues Collection: Cardiac and liver tissues obtained after dissection of the bird, washed and placed in normal saline.

Cell Extract Preparation: Cardiac and liver samples were extracted by weight 0.5 g of the tissue and add 5 ml of Tris-HCl, grinder with mortar then grinding process completed with homogenizer and cell destroyed by ultrasound. Cooled centrifugation at 10000 rpm used to obtain the cell extract.

Tissues Biochemical Parameters: Biochemical analysis same as blood.

Statistical Analysis: The program (SPSS) version (21) was used to analyze the data [6].

Results

Table (1) shows that there was no significant differences in RBCs, Hb, PCV, MCV, MCH and MCHC between sesame and control group. The result also indicate a significant decrease in variables exposed to heat stress and a clear significant differences between heat-prone group and the group exposed to heat added sesame.

Table (1): Effect of sesame seeds and heat stressed on hematological parameters in quails

The results of table (2) demonstrated that there was a significant increase in total cholesterol, triglycerides, high-density lipoprotein (HDL), very low-density lipoprotein (VLDL), LDH, ALP, AST, ALT, total protein and albumin. Also showed a significant decrease in low-density lipoprotein (LDL). Whereas the group exposed to heat stress in the presence of sesame seeds gave a significant decrease in total cholesterol, triglycerides, HDL, LDL, VLDL, LDH, ALP, AST, ALT, total protein and albumin similar approximately to that in the control group in compared with the heat group alone.Also the results indicate that there were no significantchanges between sesame group and control group except a significant increase in HDL value and a significant decrease in LDL value.

Table (2): Effect of sesame seeds and heat stressed on serum biochemical parameters in quails

Groups / Parameters	Control	Sesame seeds	Heat	Heat + Sesame seeds
	Mean ± SE	Mean ± SE	Mean ± SE	Mean ± SE
Cholesterol (mg/dl)	232.0 ± 2.00 ^{a}	244.0 ± 1.00 ^{a}	284.0 ± 6.00 ^{c}	258.0 ± 0.00 ^{b}
Triglyceride (mg/dl)	80.0 ± 1.00 ^{a}	87.0 ± 0.00 ^{a}	195.0 ± 0.00 ^{e}	130.0 ± 10.00 ^{b}
HDL (mg/dl)	120.0 ± 1.00 ^{a}	143.0 ± 1.00 ^{b}	162.0 ± 1.00 ^{c}	189.0 ± 2.00 ^{d}
LDL (mg/dl)	96.0 ± 1.00 ^{c}	83.6 ± 0.00 ^{b}	83.0 ± 5.00 ^{b}	41.6 ± 3.00 ^{a}
VLDL (mg/dl)	16.0 ± 1.00 ^{a}	17.4 ± 0.00 ^{a}	39.0 ± 0.00 ^{c}	27.4 ± 1.00 ^{b}
LDH (U/L)	1271 ± 3.00 ^{b}	1123 ± 17.00 ^{a}	1312 ± 4.00 ^{c}	1277 ± 7.00 ^{bc}
ALP (U/L)	697.0 ± 1.50 ^{a}	704.0 ± 25.00 ^{a}	946.0 ± 8.00 ^{b}	710.0 ± 6.00 ^{a}
AST (U/L)	50.0 ± 1.00 ^{a}	59.0 ± 2.00 ^{a}	94.0 ± 1.00 ^{d}	73.0 ± 1.00 ^{c}
ALT (U/L)	50.0 ± 3.00 ^{ab}	40.0 ± 0.00 ^{a}	75.0 ± 5.00 ^{b}	45.0 ± 5.00 ^{ab}
T. Protein (g/dl)	2.90 ± 0.05 ^{a}	2.90 ± 0.10 ^{a}	3.30 ± 0.05 ^{b}	3.15 ± 0.05 ^{ab}
Albumin (g/dl)	1.80 ± 0.00 ^{a}	1.75 ± 0.05 ^{a}	2.00 ± 0.00 ^{c}	1.90 ± 0.00 ^{b}
Globulin (g/dl)	1.10 ± 0.10 ^{a}	1.15 ± 0.05 ^{a}	1.30 ± 0.10 ^{a}	1.25 ± 0.15 ^{a}

*The replicates were used for each treatment.
** Based on Duncan-test, different letter refers to a significant difference between treatments at $P \leq 0.05$.

Table (3) indicates that there were a significant increase in liver tissue cholesterol, triglyceride, LDH, ALT and albumin in the heat-prone group, while sesame reduced this increase in the sesame-prone group. Whereas there was no effect on AST, proteins and globulins. As well, the results showed that there were no significant changes between sesame and control group.

Table (3): Effect of sesame seeds and heat stressed on liver biochemical parameters in quails

Groups / Parameters	Control	Sesame seeds	Heat	Heat + Sesame seeds
	Mean ± SE	Mean ± SE	Mean ± SE	Mean ± SE
Cholesterol (mg/dl)	35.5 ± 3.00 ^{a}	33.0 ± 1.00 ^{a}	76.5 ± 10.50 ^{b}	48.0 ± 0.00 ^{a}
Triglyceride (mg/dl)	66.5 ± 10.50 ^{a}	50.0 ± 6.00 ^{a}	149 ± 6.00 ^{c}	119.0 ± 3.50 ^{b}
LDH (U/L)	3587 ± 38.5 ^{a}	3554 ± 61.0 ^{a}	6278 ± 60.0 ^{c}	3944 ± 47.0 ^{b}
AST (U/L)	14.0 ± 1.00 ^{a}	14.0 ± 2.00 ^{a}	18.5 ± 2.50 ^{a}	14.0 ± 0.00 ^{a}
ALT (U/L)	63.5 ± 4.5 ^{a}	64.5 ± 2.5 ^{a}	128.0 ± 1.00 ^{c}	101.0 ± 3.00 ^{b}
T. Protein (g/dl)	1.50 ± 0.20 ^{a}	1.50 ± 0.10 ^{a}	1.95 ± 0.05 ^{a}	1.55 ± 0.05 ^{a}
Albumin (g/dl)	1.20 ± 0.00 ^{a}	1.30 ± 0.10 ^{a}	1.70 ± 0.10 ^{b}	1.35 ± 0.10 ^{a}
Globulin (g/dl)	0.30 ± 0.00 ^{a}	0.20 ± 0.10 ^{a}	0.25 ± 0.15 ^{a}	0.20 ± 0.05 ^{a}

*The replicates were used for each treatment.
** Based on Duncan-test, different letter refers to a significant difference between treatments at $P \leq 0.05$.

The result of table (4) showed a significant increase in cholesterol, triglycerides, LDH, and AST in heart tissue in birds exposed to heat stress. Sesame reduced the level of these variables in stress group in the presence of sesame. There were no significant differences between the sesame and control groups. ALT, protein, albumin and globulin not affected by heat stress.

Table (4): Effect of sesame seeds and heat stressed on heart biochemical parameters in quails

Groups / Parameters	Control	Sesame seeds	Heat	Heat + Sesame seeds
	Mean ± SE	Mean ± SE	Mean ± SE	Mean ± SE
Cholesterol (mg/dl)	18.5 ± 0.50 ^{a}	19.0 ± 1.00 ^{ab}	21.5 ± 0.50 ^{b}	20.5 ± 0.50 ^{ab}
Triglyceride (mg/dl)	19.0 ± 0.50 ^{a}	17.0 ± 1.00 ^{a}	30.0 ± 0.50 ^{b}	26.0 ± 0.50 ^{b}
LDH (U/L)	5631 ± 139 ^{a}	6762 ± 96.5 ^{b}	8102 ± 80 ^{d}	7560 ± 202 ^{c}
AST (U/L)	20.0 ± 0.00 ^{a}	30.0 ± 2.00 ^{a}	45.0 ± 5.00 ^{b}	25.0 ± 5.00 ^{a}
ALT (U/L)	17.5 ± 1.5 ^{a}	15.5 ± 2.5 ^{a}	19.0 ± 2.00 ^{a}	15.0 ± 1.00 ^{a}
T. Protein (g/dl)	1.25 ± 0.05 ^{a}	1.35 ± 0.05 ^{a}	1.40 ± 1.00 ^{a}	1.30 ± 0.00 ^{a}

Discussion

In the present study, the administration of sesame had an effective effect in reducing oxidative stress in quail males. On the light of the presented in table (1) the results which is agreement with[7] they found that exposure of broiler chicken to thermal stress significantly reduces the level of hemoglobin and hematocrit values. Also[8] which indicated that heat stress significantly alter erythrogram by decreasing RBCs, PCV and Hb concentration producing anemia of macrocytic hypochromic nature. Macrocytic hypochromic anemia developed during the period of stress due to red cell destruction or hemorrhagic anemia induced by (ROS) production and decreased antioxidant levels resulting in various deleterious effects such as enhanced membrane rigidity, osmotic fragility, membrane fluidity, reduced erythrocyte survival, and structural damage to RBC membranes, ultimately resulting in hemolytic anemia.

In addition, [5] cleared that heat stress decrease RBCs, Hb, PCV, MCH and MCHC in exposed quail to 40C° in comparison with that exposed to 22C°. The reason due to that actual body temperature of poultry may fall as much as 20C° below the normal range. Poultry are not well adapted and disposed to high ambient air temperatures. They lack sweat glands in the skin and are therefore unable to gain much from natural evaporative cooling [9].

On the other hand, the results of table (1) indicate a decrease in WBCs, lymphocytes, monocytes and granules in the heat stress group in compared with control. As well, the sesame showed a significantly increased in monocytes and granulocytes numbers.

The results, which is agreement with [8], they pointed that a significant reduction in lymphocyte and eosinophil numbers in heat stress group compared with control quail group. Also the results agreement with [7] they reported that thermal stress causes reduction in number of lymphocyte by reduction in size of lymphatic organs like spleen, thymus and bursa. In addition, significant reduction of monocyte was observed.

[10]They showed that employing sesame in broiler diet at 250 and 500 mg/kg for 4 weeks, which enhances the blood picture represented by the increase in RBC, Hb, PCV and total leucocytes count as compared with the control.

Regarding to the heat stress group given sesame, it was evident the protective effect of sesame against the negative impact of heat, through the maintaining of blood variables in this type of birds. The reason due to the high nutritional sesame content of proteins, vitamins

and minerals as well an antioxidants that plays a major role in preventing oxidative stress caused by heat. Alsoplay an important role in its oxidative stability and anti-oxidative activity [11] and [12,13] talk that sesame meal is a good source of protein and usually used as animal feed.

As for the effect of sesame on the birds exposed to stress in the table (2) its results which is agreement with [14,15] they indicated that 5% of sesame oil work significant decrease in serum triglyceride, cholesterol, LDLc, VLDLc and significant increase in HDLc in rats and lambs. In addition, they explained that the reason might be due to presence of sesamin, which is a major lignan in sesame that have lipid lowering effect as these lignans inhibits the absorption of cholesterol from the intestine.

The results also agreement with [16] they mentioned that rabbits supplemented with sesame oil 5% were found to have lower LDLc.

Others [17,18] indicated that temperature between 41-42 °C is increase in the concentration LDH in the serum of layer hence at 22 weeks old. Also [19] showed that In Vitro exposure of bone cells to hyperthermia leads to increase of vitamin D3 and ALP compared with control group. As a result, to destroy of the cells in organs, lead to release of ALP into the blood and raises it.

In addition, [20] confirmed that the chronic heat stress significantly increased AST compared to the other groups in broiler. As well, [21] demonstrate that the increasing of total proteins may due to heat shock proteins rapidly synthesized and protect the poultry under some extent of heat stress.[22] Showed that plasma cholesterol, ALT, and AST levels were higher under heat stress and decreased due to addition of 10 g/kg grape seedsin quail.

Finally,[23] demonstrate that the diet contain cooked or peeled of sesame seeds into broiler chicks leads to a significant increase in weights and indicate that seed serve as a very good source of plant protein for livestock feed.

The results of the table (3) agreement with [24] they confirmed that heat stress increases synthesis of adrenocortical hormones that will be followed by blood glucose level and body fat. Therefore, they found that peppermint extract reduces cholesterol and triglycerides in broilers.

In addition, the results agree with[25] he indicated that Sesame oil have effective hepato-protective action against lead acetate induced hepatotoxicity in mice. Also showed that levels of ALT and AST increased with co-exposure to lead and lipopolysaccharide induced liver injury but were lower with sesamin treatment.

It is worthy to mention that heat stress have significant effect on serum biochemical and electrolyte parameters of broiler chickens, which assist preliminary evaluation of the damage degree of corresponding organs [26].

Finally, regarding to the outcome of table (4) the researchers[27,28]indicated that consumption of sesame or sesamol can reduce cardiovascular by reducing cholesterol and triglyceride in rats.

The results agreement with [29] they observed significant in cardiac muscle LDH in rats exposed to diazinon toxicity and the treatment with sesame oil caused significant declines in enzyme by 80%. Also the treatment with sesame oil alone or synergistic with alph-lipoic acid showed protective effect against oxidative stress induced bydiazinon.

Conclusion

On the light of the previously results indices, it appears that the heat stress have a negative effect on haematological and biochemical parameters whether in serum or tissues. The addition of sesame caused significant positive effects on parameters thus we can use sesame as a protective agent against oxidative stress such as heat stress in quails.

Universal Exercise Unit versus Functional Resisted Training Effect on Muscle Strength in Spastic Diaplegia

Ahmed Salim Mohamed[1], Hebatallah Mohamed Kamal[2], Asmaa Osama Elsied[3], Elham Mohamed Abd El-Gafar[4]

[1]Physical Therapist, Department of Physical Therapy For Pediatrics, Banha Teaching Hospital, Banha, Egypt, [2]Professor, Physical Therapy Department for Pediatric and Its Surgery, Faculty of Physical Therapy, Cairo University, Egypt, [3]Assistant Professor, physical Therapy Department for Pediatric and Its Surgery, Faculty of Physical Therapy, Cairo University, Egypt, [4]Professor, Department of Pediatric, Faculty of Medicine, Benha University, Egypt

Abstract

Background and Objective: Strength training is one of the most important techniques in pediatric rehabilitation especially in children with CP that has no adverse effects on spasticity or R.O.M.

Aim: Comparing between effect of Universal Exercise Unit and Functional resisted exercises on the strength of lower limb muscles in children with spastic diaplegia.

Methodology: Forty spastic diaplegic children of both sexes (20 boys and 20 girls), their ages between 3 to 6 years and divided to 2 groups, (A) had Functional resisted training exercises three exercises (squatting, sit to stand, forward step up) for both lower limbs in addition to specially designed physical therapy program. (B) had Universal Exercise Unit strengthening exercise for lower limb muscles (Pushing movement) in addition to specially designed physical therapy program .peak force, Total work, Maximum work repetition, Average power, Agonist to antagonist ratio were assessed by using Biodex Isokinetic Dynamometer.

Results: Significantly improvement in pre and post treatment for study child (More improvement in B than study group A) in all measured variables.

Conclusion: It can be concluded that Universal Exercise Unit might be effective way for improving lower limb strength more than Functional resisted training exercises in spastic diaplegic cerebral palsy children.

Keywords: *Cerebral palsy, Diaplegia, Average Peak Force, Total Work, Maximum work repetition, Average power, Agonist to antagonist ratio, Universal Exercise Unit, Functional resisted training*

Introduction

Cerebral palsy is occurs in early stages and correlated with a motor impairment affecting motion and posture[1]

Spastic Diplegia is the common term applied to difference of spastic quadriparesis in which the lower limbs spasticity is more than upper limbs and detected during crawling phase. Growth of lower limbs suffer s upper torso grows normally[2]

Weakness was recorded as clinical status in spastic cerebral palsy and implied by names assigned to CP types. No evidence for support clinical bias against testing and training for individuals with CP[3]

Strength-training was encourag results with CP, partial in addressing muscle weakness and refining capabilities[4]

Muscle weakness is main factor in dysfunctional movement in those with CP[5] and related to muscle short

Ening[6] Alterations affect force-generating in muscle[7]

Universal exercise unit, therapy sessions extended are from three to four hours Children and adults have neurological conditions can used. Spider cage is made of metal could be depending on population pediatric or adults. Elastic resistance of cords used to increase strengthen of muscles[8]

Universal exercise unit (UEU) therapy is one of the treatment method that can be used other than traditional physical therapy exercises for CP children [9]

Functional strength training with anti-gravity muscles and aiming at maximal carry and could given by using resistance and gravity, weight, resistance bands and weights.[10]

Biodex Isokinetic Dynamometer provides a reliable method of testing and training of muscle performance [11]

So the purpose of this study is to compare between Universal exercise unit and functional resisted training effect on muscle strength in spastic diaplegia.

Materials and Method

Study Design: This study was a randomized controlled clinical trial. The evaluation process was conducted in the Biodex isokinetic lab at the Faculty of Physical Therapy and the intervention process were conducted in the outpatient clinic of the Faculty of Physical therapy from April 2018 till July 2018.

Subjects: Forty children with spastic diplegia, aged between 3-6 years, selected from both sexes from the outpatient clinic of the Faculty of Physical Therapy, Cairo university participated in this study, they were selected according to the following inclusion criteria:- (1) Diagnosed as C.P of spastic diaplegia (2) Degree of spasticity was 1 according to Modified Ashwarth's scale (3) Able to understand orders given to them. Exclusive criteria: (1)No fixed deformities (2)Neither visual nor auditory problems (3)Neither perceptual nor cognitive problems.

Procedures: The study was conducted after the approval of the ethical committee of the Faculty of Physical therapy, Cairo University.All participants (Child's parents) gave their informed consent for participation. The test procedures were explained to each participant. All participants' rights to privacy were protected. All participants were protected from harms.

Evaluation process:

Measuring lower limbs muscle strength: Peak force, maximum work repetition, totalwork, average power, Agonist to antagonist ratio was detected by using Biodex Isokinetic Dynamometer.

1. **Collection of personal data:** Included name, age, weight, addresses and telephone number.
2. **Testing Session:** Children were educated and were informed of the purpose and intention of the test.
   (a) **Starting position:** 45 degree flexion for both hips and knees.
   (b) **Range of motion:** From 45 degree flexion to 0 degree extension.
   (c) **Pushing velocity:** 9.17 m/sec.
   (d) **Movement repetitions:** 5 repetitions.

The Child was in semi reclined position and the trunk fixed by straps and the child was asked to move or push the handle[12]

Treatment intervention:

For Study group A: Children of this group received Functional resisted training exercises including three exercises (squatting, sit to stand, forward step up) for both lower limbs in addition to specially designed physical therapy program to manage the other problems.

1. **Squatting:** The squat begins in upright with knees and hips fully extended and squats down in a continuous motion till desired squat depth in continuous motion ascends return to upright position[13]
2. **Sit to Stand:** Performing the Exercise (A)The child Sit on a stool)B)The child Slide forward as far as possible)C)The child Moves his feet back so his heels are lined up with the front edge of the chair)D) The child Uses his butt and legs to stand up[14]
3. **Forward step up:** Child placed entire right foot onto t chair. Press right heel onto bench, bring his left foot to meet his left so he was stand on bench[15]

For Study group B: Children of this group received

Universal Exercise Unit strengthening exercise for lower limb muscles (Pushing movement) addition to specially designed physical therapy program.

Universal exercise unit

Child Position: Supine lying position on the table inside the spider cage, child fixed with straps on the chest, pelvic, and on the non-involved limb while the other lower limb is free to perform exercise.

Child is asked to push his\her lower limb against weight. The child performed this movement 10 repetitions at first then increase every session with the estimated weight till 10 sets then increase weight and decrease sets to one set. we can calculate weight by using Fixed Percentage of a Person's Body Weight Method[16] and repetitions by using one Maximum Repetition, training start with dynamic warm-up, initially 1 or 2 sets of 8–15 repetitions with a light to moderate load (about 30–60% 1 RM) [17]

Results

In the present study, the therapeutic efficacy of the universal exercise unit versus functional resisted training effect on muscle strength in spastic diaplegia was investigated, peak force, maximum work repetition, total work, average (AVG) power and agonist/antagonist (AGON/ANTAG) ratio were be assessed before treatment (pre-treatment) and after three successive months of treatment (post) for each patient in both groups (A and B).

Regarding the age in both groups (A and B), the results of the present study revealed a statistically insignificant deference between the two groups as the mean values of the age were 55 ± 10.6 years and 53.7 ± 10.7 years, respectively with p>0.05 **(Table 1).**

Table (1): Mean values of age (months) within studied groups.

Variable		Mean±SD	Range	t-value	p-value
Age (Months)	Group (A)	55±10.6	36 – 72	0.51	0.615 NS
	Group (B)	53.7±10.7			

SD: Standard Deviation. NS: Non-Significant.

A statistically insignificant deference (p>0.05) was recorded as mean values of groups (A and B) pretreatment were 87.16 ± 6.52 and 86.38 ± 7.39 for peak force, 182.42 ± 16.27 and 178.37 ± 13.38 for total work, 35.44 ± 4.85 and 37.3 ± 6.32 for average (AVG) power, 60.02 ± 9.98 and 59.11 ± 9.6 for agonist/antagonist ratio respectively **(Table 2)** and 2 and 2.5 for maximum work repetition **(Table 3).**

Comparing mean values after treatment application between groups (A and B) showed a statistically significant deference as mean values were 101.07 ± 8.98 and 108.35 ± 9.57 for peak force, 203.51 ± 14.93 and 223.13 ± 20.82 for total work, 44.02 ± 5.46 and 49.43 ± 7.39 for average (AVG) power, 67.52 ± 10.06 and 80.37 ± 7.7 for agonist/antagonist ratio respectively **(Table 2)** and 3 and 4 for maximum work repetition **(Table 3).**

Table (2): Mean ± SD pre and post treatment mean values of studied groups.

Variable	Time of Treatment	Group (A)	Group (B)	t-value	p-value
Peak force	Pre	87.16 ± 6.52	86.38 ± 7.39	0.35	0.727

Discussion

The selection of muscle strength to be evaluated in the present study also come in agreement with **Diamond and Armento**[18] who stated that all CP give relative atrophy of pelvis and lower limb muscles and secondary short stature.

Choosing Biodex Isokinetic Dynamometer for muscle strengthening evaluation was accepted by pervious studies such as **ALangari, and AL-Hazzaa**[19] reported that, Isokinetic illustrated highly reproducible and extensively used to evaluation of muscle strength.

Present study focused on the following parameters of the child's muscle strength; peak force, Total work, Maximum work repetition, Average power, Agonist to antagonist ratio which are evaluated by Biodex Isokinetic Dynamometer.

The previous data were collected to compare between pre-treatment differences of the two groups (2 study groups), pre and post treatment differences of the same groups and post treatment differences of the two groups.

Results were revealed no significant differences in variables; this confirms method that used in the two groups. Significant differences were observed when comparing before and after treatment mean values of measuring variables and supported by using physical therapy modalities in improving lower limb muscle strength (average peak force, total work, Maximum work repetition, Average power, Agonist to antagonist ratio).

Progressive loss of muscle strength with spasticity, interferes affected with motor rehabilitation **Scholteset** CP has to generate strength is rarely evaluated and quantified, and consequently prioritized to the goals of a treatment[20]

Taylor et al[21] found increase capacity to generate strength carrying CP one could cite progressive resistance exercises and gait established functional parameters, motor dexterity and conditioning

Damianoet al[22] concluded that children with normal motor development, as well as carrying spasticsdiplegia increase their capacity to generate strength when submitted to a resistive training. **Thompson et al** reported less ability to generate strength in muscle of lower limbs, except for hip extensors outcome of strengthening on CP patients. Isotonic, isometric, and isokinetic exercises using as faster increase muscle strength [23]

Increase average peak force, total work, Maximum work repetition, Average power, Agonist to antagonist ratio. These results could be attributed to strengthening of lower extremity muscles that might have caused of sufficient force. Muscle strengthening found in such children is necessary to produce joint stability and adequate equilibrium reactions agreement results with **Karimi et al [24].**

Concerning the pre -treatment data and post treatment results of the measured variables (average peak force, total work, Maximum work repetition, Average power, Agonist to antagonist ratio)of mild spastic diplegic children of both groups by using Biodex Isokinetic Dynamometer, the results revealed significant improvement in both groups ($p< 0.05$).

The significant improvement in the post treatment mean values of both groups might be attributed to the effect of selected physical therapy program, directly toward inhibiting abnormal muscle tone, abnormal postural reflexes, facilitating normal patterns of postural control and developing differ in normal movement trunk and decrease extremities.

Improving in study group A might be attributed to improvement of muscle strength (average peak force, total work, Maximum work repetition, Average power, Agonist to antagonist ratio) due to the effect of functional resisted training; this is supported by **Shepherd and Adams**[25] task specific training yields long lasting

cortical re organization and is specific to the areas of brain being used with a task. **Blundell and Shepherd**[26] found, non-weight bearing exercises may have limited transfer ability to actions that are weight-bearing and involve different and more complex patterns of muscle activation.

Higher improvement in the study group B (average peak force, total work, Maximum work repetition, Average power, Agonist to antagonist ratio) might be due to the effect of UEU; this is supported by **Koscielny**[27] UEU is a large, metal, three dimensional cages that houses a system of pulleys and bungees. Particular muscle group to work without compensations in order to enhance a specific movement necessary to achieve a functional skill.

Also this is supported by **Richard Koscielny**[28]who stated that the UEU is a versatile tool consisting of a system of pulleys, straps, and splints using during all stages of therapy. Pulley system enables one to isolate the desired muscle group work on specific movement or function. System of exercises performed range of motion, both active and passive, and improved muscle flexibility and tone.

Conclusion

Universal Exercise Unit and Functional resisted training is useful therapeutic modality increase lower limb muscle strength in spastic diplegic cerebral palsied children.

Abstract

Diabetes is a chronic disorder associated with abnormally high levels of the sugar glucose in the blood. Research has continued to study medicinal plants extracts for reducing blood sugar.

The present study aimed to evaluate the effect of using Cinnamon extract, at a dose of 2000 mg/kgB.W, and Sodium Selenite at a dose of 0.05 mg/kg diet, on Ceruloplasmin and Leptin hormone concentrations ond rabbits to overcome the toxic effects of Alloxan as well as to renovate and repair the damage in tissue caused at a dose of 400 mg/kg B.W by intraperitoneal injection.

The results of the study showed that the experimental diabetes by Alloxan at a dose of 400 mg/kg B.W resulted in a significant decrease ($P \leq 0.05$) in the concentration of Ceruloplasmin and Leptin hormone in the plasma of males and femalesrabbits., whereas treatment with Cinnamon and Sodium Selenite increased Ceruloplasmin and Leptin hormone in rabbits blood plasma.

Keyword: *Cinnamon, Leptin, plasma, Ceruloplasmin.*

Introduction

Many researchers in the field of public health dealt with Diabetes; its causes, complications and the required procedures to avoid developing this disease or mitigating its influences. Diabetes Mellitus is known as a condition caused by high blood sugar levels, which is caused by insulin imbalance, by reduction of its level in blood or increment in the factors inhibiting its influence. This disturbance leads to abnormalities in the metabolism of the body's basic substances (carbohydrates, lipids, and proteins) and disturbs the distribution of water and electrolytes. Diabetes comes in the forefront of diseases resulting from glands malfunctioning [1]. International and local research has continued to study medicinal plants for reducing blood sugar, one of these plants used to reduce the level of blood sugar is *Cinnamomum zylanicum*.

Selenium, on the other hand, is an essential component of the diet of humans and most animals, and it has a major role in metabolic processes. It is an antioxidant that the body needs in small amounts and is an essential component of the enzyme (GSH-px). Soil and water are the main source of Selenium in plants and animals. Selenium is in an inorganic form that can turn into different oxidation states under certain conditions.

Leptin is a hormone that regulates B.W and it consists of 167 amino acids, and is excreted from adipose

tissue, and some of it is excreted from the hypothalamus, stomach, placenta, skeletal muscles.[2]. Leptin was discovered by the researcher Zhang and his group in 1994[3], after isolating the obesity gene responsible for hormone formation by recombinant technology DNA on chromosome 6 when they found that mutations in these genes cause obesity in mice. Leptin is found in adipose tissues, especially subcutaneous adipose tissue where its level is 106 times higher than in the brain [4].

The aim of this study was to investigate the effect of Cinnamon and Sodium Selenite on Ceruloplasmin and Leptin in bloodplasmaof healthy rabbits with experimental diabetes.

Materials and Method:

Materials: Alloxan and Sodium Selenite were obtained from a bureau of medical supplies in Nineveh, In this study, 54 male and 54 female rabbits, ages of 9-12 months and weights ranging from 1250 to 1500g,; confirmed free of disease via periodic inspection by veterinarians from the Faculty of Veterinary Medicine. They were placed in specially made metal cages, under suitable conditions of temperature, 25 °- 28°C, and a period of lighting of 14 hours a day with good ventilation presented using aluminum containers in equal quantities and in a fixed sequence for all treatmentsWater was given to rabbits by containers attached to the cage from outside to prevent spilling.

A standard dietfor rabbits with a protein content of 16.5% was used in this study. This ratio was determined by the N.RC[5].Components used were the same adopted by [6].

The calculated energy in the diet was 2213 kilocalorie/kg diet according to the recommendations adopted by the N.R.C[5].

In this study we used the bark of cinnamon tree, and its classification was verified depending on [7]. The scientific name of the plant is (*Cinnamomum Zeylanicum*).

Preparation of cinnamon extract: For an easy and inexpensive method of preparation; cinnamon bark was cut into small pieces, then boiled water was added to 20 g of chopped cinnamon, left to boil for 30 minutes and then filtered to obtain watercinnamon extract [8] at a concentration of 2000 mg/ml of the extract after filtration,

Induction of Experimental Diabetes: Fodder was discontinued from rabbits for 24 hours before being injected with Alloxan at a concentration of 400 mg/ kg of B.W[9]. Alloxan was dissolved inphysiological solution immediately before use in a single dose under the intraperitoneal membrane [10].

Rabbits were fed and drinking water was replaced with 10% glucose solution after injection, for 24 hours, to reduce Hypoglycemia shock due to Aloxan treatment[11]. Treated rabbits' blood samples were taken to measure glucose level every two days during the first week of injection to ascertain the incidence, and to observe signs of extreme fatigue and frequent urination [12]. After confirming the development of diabetes, the rabbits were left for 40 days under observation for the purpose of adapting to the disease and producing complications on the body.

After randomly dividing the rabbits into six groups for each sex, the rabbits of each group were weighed after keeping off the fodder for 12 hours; the average primary weights were calculated and recorded for each group as a primary weight. Final weight was calculated after eight weeks of starting the treatment.

Blood samples were obtained by cardiac punctureto obtain plasma for the measurement of Ceruloplasmin and leptin hormone.

Rabbits were randomly divided into six groups (9 rabbits/group) for each sex. After the preliminary period, the treatment of rabbits started to be daily for 8 weeks.

Method: Ceruloplasmin concentration in plasma was estimatedusing the modified method of [14].

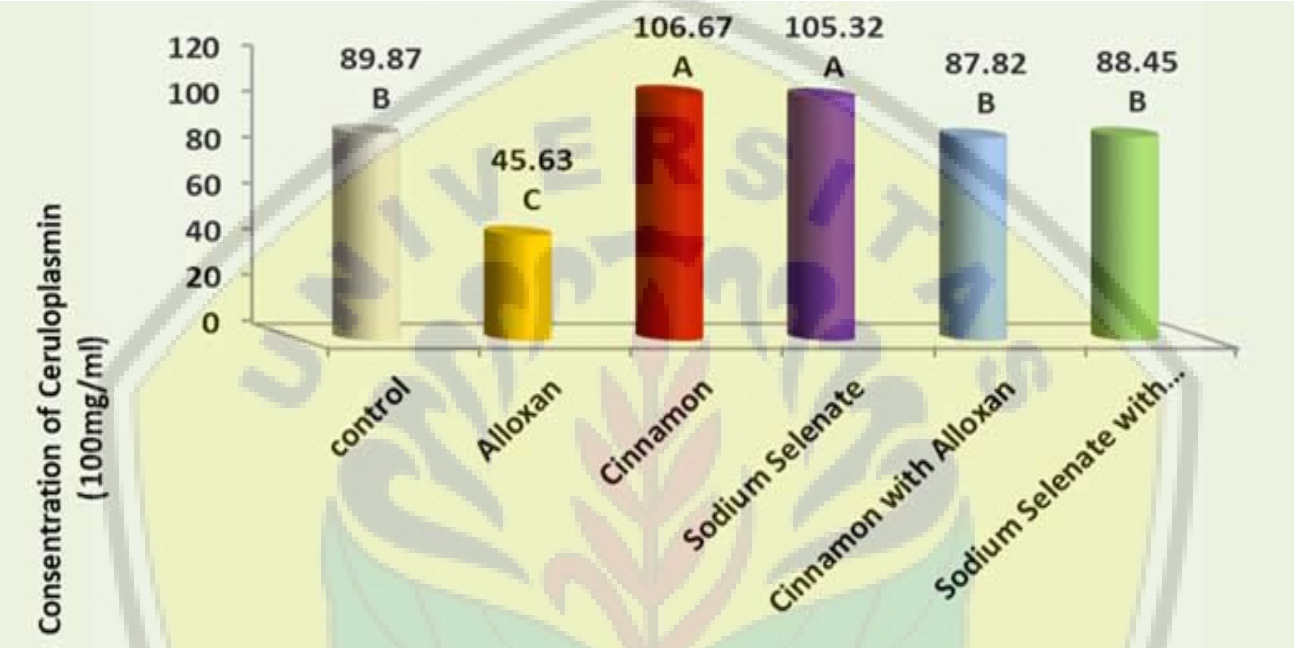
The concentration of Leptin in plasma of malerabbits was estimated using the analysis kit and then estimated at 450 nm wavelength.

Statistical analysis was performed using one way analysis of variance (C.R.D). Differences among the groups were determined using the Duncan's Multiple Range Test for all measurements in the study and the level of statistical discrimination was ($P \leq 0.05$)[15], usingSAS (2001).

Results and Discussion

In Figure (1), a significant increase was observed in Ceruloplasmin concentration in the plasma of male rabbits of Cinnamon group and Sodium Selenite group

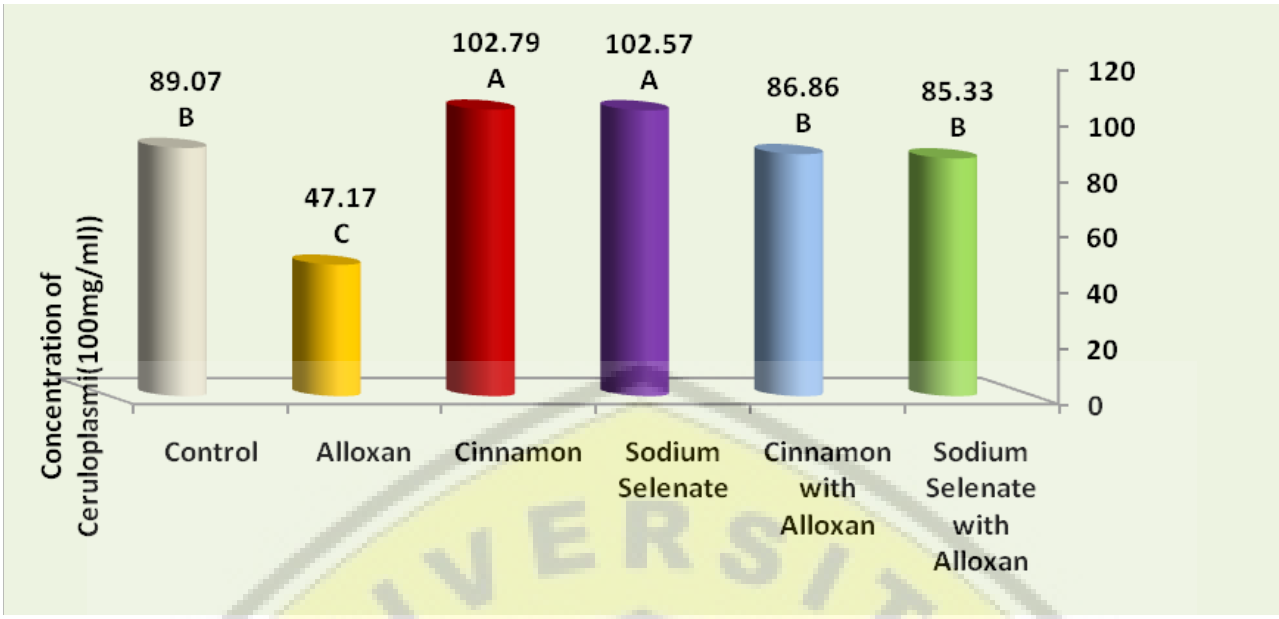
compared to other treatments, where the arithmetic mean of cinnamon group was 106.67mg/100 ml and for the Sodium Selenite group 105.32mg/100 ml, whereas the Alloxan group showed a significant decrease in Ceruloplasmin concentration in the plasma of malerabbits compared to other treatments, with an arithmetic mean of 45.63mg/100 ml. The group of Cinnamon with Alloxan and the group of Sodium Selenite with Alloxan improved the concentration of Ceruloplasminto reach the control level, where the arithmetic mean of the group of Cinnamon with Alloxan was 87.82mg/100 ml and for the group of Sodium Selenite with Alloxan was 88.45mg/100 ml. The control had a mean of 89.87mg/100 ml.



Values are expressed in arithmetic mean (±) standard deviation and the number of rabbits/group = 9
Figures associated with different letters indicate a significant difference at a probability level ($p \leq 0.05$)

Figure 1: Effect of treatment with cinnamon extract and of Sodium Selenite on Ceruloplasmin concentration (mg/100m) in plasma of healthy male rabbits having experimental diabetes.

Figure (2)shows a significant increase) in Ceruloplasmin concentration in the plasma of female rabbits of the Cinnamon group and the of Sodium Selenite group compared to other treatments, where the arithmetic mean of Cinnamon group was 102.79mg/100 ml and for the Sodium Selenite group 102.57. Whereas the Alloxan group showed a significant decrease in Ceruloplasmine concentration in the plasma of female rabbits compared to other treatments, where its arithmetic mean was 47.17mg/100 ml. The group of Cinnamon with Alloxan and the group of Sodium Selenite with Alloxan improved the Ceruloplasmin concentration to reach the control level. The arithmetic mean of the group of Cinnamon with Alloxan was 86.86mg/100 ml and the group of Sodium Selenite with Aloxan was 85.33mg/100 ml, whereas the control had a mean of 89.07mg/100 ml.



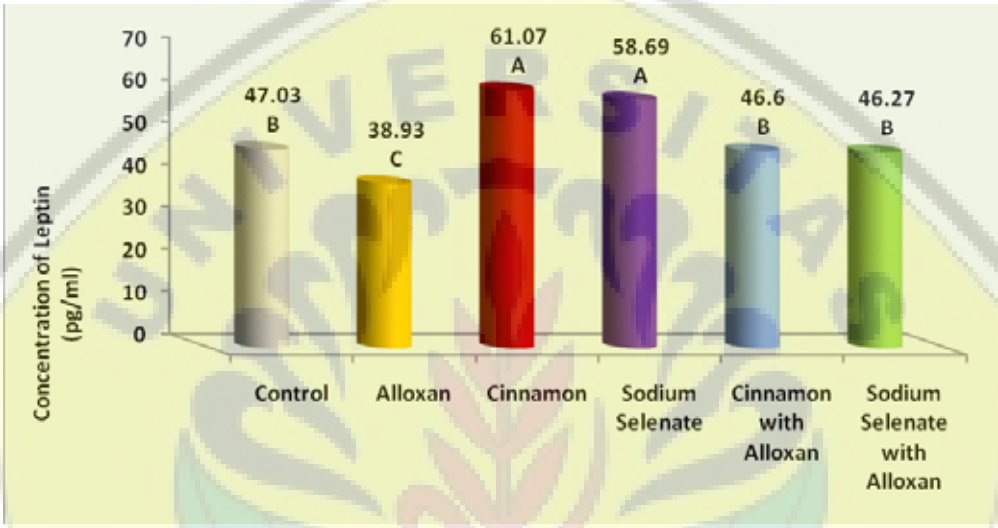
Values are expressed in arithmetic mean (±) standard deviation and the number of rabbits/group = 9
Figures associated with different letters indicate a significant difference at a probability level ($p \leq 0.05$)

Figure 2: Effect of treatment with Cinnamon extract and Sodium Selenite on Ceruloplasmin concentration in plasma of healthy female rabbits with experimental diabetes.

The increased concentration of Ceruloplasmin can be attributed to the high content of Cinnamon extract on polyphenols, flavonoids and glycosides, which reduce oxidative stress by removing free radicals and increasing concentrations of antioxidants and activating them, especially antioxidant enzymes such as Catalase, (SOD),(GSH-px)., and Glutathione reductase. Thus reducing the effect of oxidative stress on ceruloplasmin, which results in increase of its concentration in blood and prevents its interaction with mineral ions[16]. In addition to inhibition of the process of peroxidation of lipids andreducing the concentration of free cholesterol and LDH-C by breaking down the chain of diffusion reactions of free radicals and thereby increasing the concentration of Ceruloplasmin in plasma[17],[18].

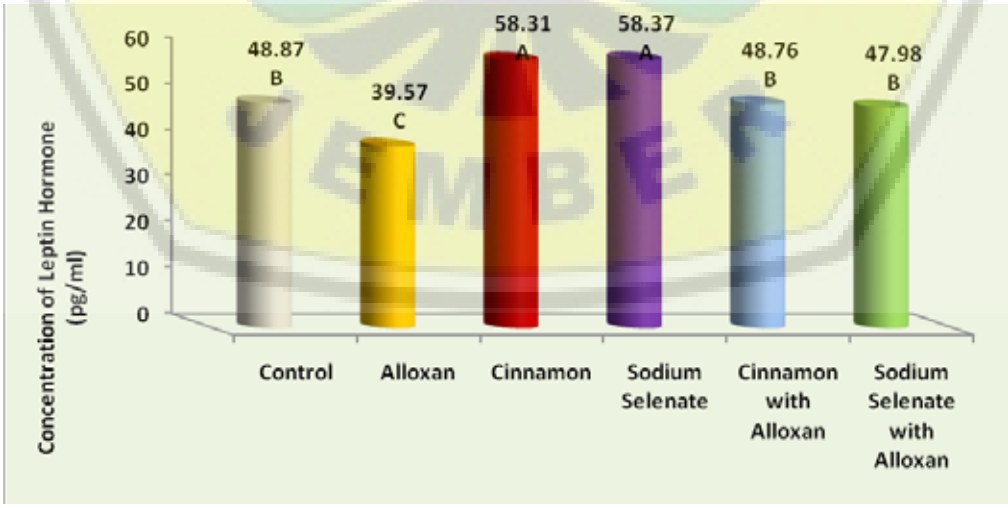
The low concentration of Ceruloplasmine in the Alloxan group can also be attributed to the low concentration of hemoglobin asreduced Ceruloplasmin is associated with anemia because it is necessary to release iron from its reservoirsas well as being necessary to exploit iron naturally by the Normoblast to build hemoglobin [19]. This association between hemoglobin and Ceruloplasmin is through the latter's role in the transfer of iron from its reservoirs in the liver to the position of hemoglobin formation inthe bone marrow, and thus, the formation of erythrocytes. Accordingly low concentration of hemoglobin is associated with low Ceruloplsmin[20].This might also be attributed to the lack of Ferritin retaining iron, transferrinand the low iron in the blood serum [21]. The reason might also be attributed to the low basal metabolic rate [22].Another reason might be that Ceruloplasmin is a protective antioxidant that prevents the formation of free radicals by binding to minerals such as iron Fe^{+} 2and copper ion (Cu2) and preventing the formation of free radicals [22][23]. This decrease may be due to complications of diabetes and the resulting high concentrations of free radicals, which induce Ceruloplasmin to remove these free radicals, thereby reducing its concentration in the blood [24]. Figure (3) shows a significant increase in the concentration of Leptin hormone in serum of male rabbits for the Cinnamon group and Sodium Selenite group compared with other treatments where the arithmetic mean of Cinnamon group was 61.07pg/ml and for the Sodium Selenite group 58.69pg/ml, whereas the Alloxan group showed a significant decrease in the concentration of Leptin hormone inplasma of malerabbits compared to other treatments where its arithmetic mean was 38.93pg/ml.Results showed an improvement in the concentration of Leptin hormone in the group of Cinnamon with Alloxan and ofarithmetic mean equals

to 46.6 pg/ml, and in the group of Sodium Selenite with Alloxanof arithmetic mean equals 46.27pg/ml, until their level reached the control group of arithmetic mean equals 47.03pg/ml. Figure (4)shows a significant increase in the concentration of Leptin hormone in sera of femalerabbits for Cinnamon group and Sodium Selenite group compared to other treatments, where the arithmetic mean of Cinnamon group was 58.31pg/ml, and for Sodium Selenite group 58.87pg/ml. Alloxan group showed a significant decrease in the concentration of Leptin hormone in sera of female rabbits compared to the other treatments, where its arithmetic mean was 39.57pg/ml. The group of Cinnamon with Alloxan and the group of Sodium Selenite with Aloxan improved in the concentration of the Leptin hormone with an arithmetic mean of 48.76pg/ml for the group of Cinnamon with Alloxan, and 47.98pg/ml for the group of Sodium Selenite with Alloxan, till their levels reached that of the control withan arithmetic mean 48.87pg/ml.



Values are expressed in arithmetic mean (±) standard deviation and the number of rabbits/group = 9
Figures associated with different letters indicate a significant difference at a probability level (p≤0.05)

Figure 3: Effect of treatment with cinnamon extract and Sodium Selenite on the concentration of Leptin hormone (Pg/ml) in plasma of healthy male rabbits with experimental diabetes.



Values are expressed in arithmetic mean (±) standard deviation and the number of rabbits/group = 9
Figures associated with different letters indicate a significant difference at a probability level (p≤0.05)

Figure 4: Effect of treatment with Cinnamon extract and Sodium Selenate on the concentration of Leptin hormone (Pg/ml) in plasma of healthy female rabbits with experimental diabetes.

High concentration of Leptin in the group treated with Cinnamon at a concentration of 2000 mg/kg B.W may be due to a positive relationship between the Leptin hormone and the concentration of insulin hormone and the level of glucose in the blood, and because Cinnamon contains Cinnamaldehyde, Eugenol and Polyphenol, which have significant role in stimulating the secretion of Insulin from beta-pancreatic cells. Increased insulin secretion increases the formation of Leptin hormone mRNA in the adipose tissue and then secretes Leptin to increase glucose metabolism [25]. Whereas the low level of Leptin in the group treated with Alloxan may be due to increased oxidation and burning of fat to produce energy from adipose tissue as well as low levels of insulin, which has a positive relationship with Leptin [26].

Abstract

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder among women of reproductive age. PCOS is associated with metabolic abnormalities, including insulin resistance. Dietary supplements, including chromium, are attractive strategies for alleviating insulin resistance. Several studies have been conducted to investigate the effect of chromium supplementation on PCOS. Therefore, the present review aims to highlight the impact of chromium supplementation on insulin resistance among women suffering from PCOS. Clinical trials were chosen to examine the effect of chromium picolinate supplementation among women with PCOS. The results demonstrated the beneficial effects of chromium supplementation as it decreased fasting blood sugar, serum insulin, and insulin resistance. These findings suggest that supplementing PCOS patients with chromium may alleviate insulin resistance.

Keywords: *Chromium picolinate, Insulin resistance, Polycysticovary syndrome.*

Introduction

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder among women, affecting approximately 5–10%. It causes anovulation and infertility in women during their reproductive age[1,2]. The risk of PCOS increases as a result of obesity, particularly increased abdominal fat[3]. PCOS is characterized by an increased prevalence of impaired glucose tolerance and insulin resistance.

The manifestation of PCOS and insulin resistance maybe improved through a healthy diet and regular exercise. The impact of the diet's macronutrient com position on PCOS has been previously studied [4]. In addition, growing evidence suggests that trace elements, such as copper, zinc, magnesium, calcium, manganese, and chromium, play a role in the pathogenesis of PCOS[5].

Chromium (Cr) is an essential nutrient for both humans and animals. In general, the organic forms of Cr are better absorbed than the inorganic forms[6]. The metabolic effects of Cr are affected by its ingested formulation. Chromium picolinate is a common form of Crfound in dietary supplements [7,8].

Crhasbeenrecognizedasanessentialmineralrequired in the insulin signal cascade[9]. Daily supplementation of 200–1000 mcg of chromium picolinate may decrease

blood glucose concentration[8]. Recent studies found that chromium supplementation improves PCOS patients' insulin metabolism and resistance conditions[10] pre-diabetic condition that precedes the onset of type 2 diabetes. The signs and symptoms of insulin resistance are similar to those of the insufficient dietary intake of Cr, including glucose intolerance; hyperinsulinemia; decreased HDLcholesterol and lean body mass; and increased LDL cholesterol, triacylglycerols, total cholesterol, and fat mass[11]. Insulin resistance offers potential avenues for early intervention to treat different diseases.

The majority of the recent available drugs that improve insulin sensitivity have adverse effects. Therefore, dietary supplements, such as Cr, are attractive strategies to alleviate insulin resistance[12,13]. However, studies investigating the effects of Cr on PCOS patient improvement are limited. Therefore, the present study aims to conduct a narrative review of the findings of previous studies that explored the impact of chromium picolinate on the insulin resistance indices among PCOS patients.

Methodology

The impact of Cr supplementation on insulin resistance among women suffering from PCOS was searched electronically using different databases, including Medline, Pub Med, and Google Scholar. All the studies published in the last 10 years period (2008–2018) were considered. Initially, 560 abstracts were found and evaluated based on the inclusion and exclusion criteria. The review included pilot, clinical, and randomized control trials that study the effects of chromium picolinate supplementation on PCOS patients. None of the animal studies, reviews, or qualitative research were included in this review. Case reports, essays, and blogs were also excluded due to the lack of reliability and authenticity. Therefore, a total of 7 articles qualified for use in this review.

Results and Discussion

The qualified articles in this review investigated the effects of daily chromium picolinate supplementation on insulin resistance and its related parameters among PCOS patients (Table 1).

Table 1: Characteristics of the Included Studies

Author (Year)	Sample Size	Age Criteria	Study Design	Chromium Dose and Duration	Outcome
Lucidi et al.[14]	10 PCOS women	18–39 years	Pilot study	Chromium picolinate (200 µg/d) or placebo for 4 months	Significant decrease in OGTT 1-hour glucose (mg/dL) and OGTT 2-hour glucose (mg/dL)
Amooee et al. [7]	92 women with clomiphene citrate-resistant PCOS	-	Randomized clinical trial	Chromium picolinate (200 µg/d) for 3 months	Reduced fasting blood sugar and serum insulin levels and increased insulin sensitivity
Jamilian and Asemi [15]	64 Women with PCOS (according to Rotterdam criteria)	18–40 years	Randomized double-blind, placebo-controlled, clinical trial	Chromium picolinate (200 µg/d) for 8 weeks	Favorable effects on insulin metabolism markers
Jamilian et al. [17]	40 infertile PCOS women candidates for IVF	18–40 years	Randomized double-blind, placebo-controlled trial	Chromium picolinate (200 µg/d) for 8 weeks	Beneficial impact on the patients' glycemic control
Lydic et al. [18]	10 PCOS patients	19–42 years	Pilot Study	Chromium picolinate (1,000 µg/d) for 2 months	Significantly reduced the glucose disposal rate
Ashoush et al. [19]	85 PCOs patients	20–35 years	Double blinded randomized controlled trial	Chromium picolinate (1000 mcg/day) for 6 months	Reduced insulin resistance among PCOS patients.
Fogle et al.[20]	25 PCOS women	-	Randomized control trial	(500 µg) twice daily for 3 months	Had no effect

Four studies used 200 µg of chromium picolinate in their experiments. Lucidiet al.[14] found that the daily supplementation of 200 µg of chromium picolinate for 4 months improved glucose tolerance. Similar findings were reported by Amooee et al.[7] who studied the effects of 200µg/d of chromium picolinate for 3 months among clomiphenecitrate-resistant PCOS patients. The results showed a significant decrease in fasting blood sugar and serum insulin levels that resulted in an increase in insulin sensitivity, which was measured using the quantitative insulin sensitivity check index (QUICKI). Jamilian and his research group studied the effect of the same dosage of chromium picolinate supplementation for a shorter period of time (2 months only). Their results from the study of 2015 showed that there were significant decreases in serum insulin levels and HOMA-IR as well as a significant increase in the QUICKI score among PCOS patients[15,16]. The same group found that chromium administration for 8 weeks to infertile PCOS women candidates for IVF had beneficial impacts on glycemic control as well as significant reductions in fasting plasma glucose and insulin levels. In addition, their results found improvement in insulin sensitivity as showed by the significant increase in QUICKI score and decrease in HOMA-IR[17].

The rest of the studies that qualified for this review examined the effect of higher doses of chromium picolinate on PCOS. Lydicet al.[18] demonstrated that 1,000 µg/d chromium picolinate supplementation for two months improved the glucose disposal rate among obese women suffering from PCOS by 38%[18]. Ashoush et al. [19] administered 1,000 µg/d of chromium picolinate for a longer period time (6 months) and found a significant reduction in fasting serum insulin and significant increase in the fasting glucose insulin ratio[19]. However, one study showed no significant changes in fasting glucose, insulin, and HOMA-IR from 1,000 µg/d chromium picolinate supplementation for three months among Hispanic and morbidly obese PCOS-IR patients[20]. These opposing findingsmay be explained by the different characteristics of the study participants, such as race and morbid obesity

Conclusion

According to the selected studies, daily 200-1000 µg chromium picolinate supplementation reduces insulins resistance in PCOS patients.

Role of Nerve Ultrasound in Diagnosis of Guillain-Barré Syndrome

Manal Mahmoud Al Kattan[1], Ehab Shaker Hafez Belal[1], Sandra Mohamed Ahmed[2], Basma Bahgat El Sayed[3], Osama Yacoub Mohamed[4]

[1]Professor of Neurology, [2]Assistant Professor of Neurology, [3]Assistant Professor of Neurophysiology, [4]Assistant Lecturer of Neurology, Neurology Department, Faculty of Medicine, Cairo University, Egypt

Abstract

Objective: To assess role of ultrasound (US) in diagnosis and follow up of Guillain-Barré syndrome (GBS) patients.

Method: We prospectively recruited 24 GBS patients and 40 healthy controls. Cross-sectional areas (CSAs) measured by nerve US and nerve conduction studies (NCS) were performed within the first week of disease onset and repeated after follow up period about 3 months.

Results: Nerve CSAs were significantly enlarged in most of examined peripheral nerves when assessed at disease onset compared to controls. However, no significant difference could be found when compared with follow up measures.

Conclusion: US measurement of CSA of the peripheral nerves could be a reliable non-invasive imaging modality helps in diagnosis of GBS.

Keywords: *Guillain-Barré syndrome, Nerve ultrasound, Cross-sectional area, Nerve conduction studies.*

Introduction

Guillain-Barré syndrome (GBS) is immune-mediated post-infectious disease that affects peripheral nervous system. Its common types are the acute inflammatory demyelinating polyradiculoneuropathy (AIDP), the acute motor axonal neuropathy (AMAN) and acute motor & sensory axonal neuropathy (AMSAN). GBS diagnosis is settled through history, clinical examination, cerebrospinal fluid analysis and electrophysiological features of neuropathy[1].

The electrophysiological changes in GBS patients may appear late which make early diagnosis within the first week is difficult[2,3]. In GBS, there have been many studies that have investigated the role of peripheral nerve US[4,5,6,7,8,9]. Most have investigated the use of nerve US in the early stages of GBS[6,8,9], where nerves are seen to be enlarged in comparison to controls.

In this study we prospectively performed peripheral nerve US and NCS in GBS patients to measure CSAs within onset of symptoms and after a period of follow up and to correlate them with NCS.

Methods

Subjects: This study was conducted on 24 patients with GBS. We recruited patients from Neurology Department - Kasr Al-Ainy from April 2017 to October 2018. These patients were compared to 40 healthy controls within one week of disease onset, 17 of them only were assessed after follow up period about 3 months as 1 patient died shortly after onset and 6 patients were lost at follow up. Inclusion criterion was adult patients with GBS; acute inflammatory demyelinating

e-mail: osamayacoub@kasralainy.edu.eg

polyradiculoneuropathy (AIDP), acute motor axonal neuropathy (AMAN) and acute motor & sensory axonal neuropathy (AMSAN), according to published criteria[1]. Exclusion criteria were; patients with recurrent inflammatory neuropathy, patients with history of any medical condition that could affect peripheral nerve diameter e.g. thyroid disease and patients with history of entrapment neuropathy. Disability was classified using the Hughes Score (HS)[10,11] ranging from 0 (normal) to 6 (death) The study was approved by the local Ethics Committee, and all patients and controls gave their informed consent to participate in the study.

Nerve Conduction Studies: Nerve conduction studies were carried out in the clinical neurophysiology unit, Kasr Al-Ainy, Cairo University using a Neuropack MEB9200 four channels apparatus. Measurements were done, according to Preston and Shapiro[12]. Motor studies were performed on ulnar, median, radial, posterior tibial and common peroneal nerves. Distal motor latency, amplitude, conduction velocity and F wave response were recorded. Sensory nerve conduction studies were done on ulnar and superficial peroneal nerves, where latency, amplitude and conduction velocities were recorded.

Nerve Ultrasound: Nerve Ultrasound was performed by expert neuro-sonographer operator using qualified system (Philips IU22 xMATRIX, California, US), no special preparation for the examination. This examination was done at Neurology department, Kasr Al-Ainy, Cairo University. It was performed on an affected arms and legs, and the nerves were scanned in axial planes, and the cross-sectional area (CSA) of each nerve was measured at standardized anatomical points; median nerve: at carpal tunnel inlet, junction between distal 1/3 and proximal 2/3 of forearm, antecubital fossa and junction between distal ¼ and proximal ¾ of the arm. Ulnar nerve: at Guyon's canal, junction between distal 1/3 and proximal 2/3 of forearm, 5 cm distal to elbow between 2 heads of flexor carpi ulnaris, at cubital canal and 5 cm distal to cubital canal. Radial nerve: at radial groove close to the shaft of humerus. Tibial nerve: just posterior to the medial malleolus and at the popliteal fossa adjacent to the popliteal artery. Peroneal nerve: just distal and anterior to the postero-lateral aspect of the knee before it turns around neck of fibula.

Statistics: Data was analyzed using IBM SPSS advanced statistics version 24 (SPSS Inc., Chicago, IL). Numerical data were expressed as mean and standard deviation or median and range as appropriate. Qualitative data were expressed as frequency and percentage. For quantitative data, comparison between two groups was done using Mann-Whitney test. Spearman-rho method was used to test correlation between variables. A p-value < 0.05 was considered significant.

Results

This study carried on 24 GBS patients. All of them were examined within first week of disease onset. 17 of them were assessed after follow up period about 3 months. 1 patient died shortly after onset and 6 patients were lost, and 40 normal healthy subjects served as controls. Patient's characteristics were shown at table (1).

Table (1): Characteristics of the patients' group.

Patient's characteristics		**n = 24**
Age, mean ± SD		36.38±12.16
Gender (Male : Female)		13:11
Sensory affection, n (%)	At onset	7(29.2)
	During the course	16(66.7)
Autonomic dysfunction, n (%)		3(12.5)
Cranial nerve affection, n (%)		12(50)
Respiratory affection, n (%)		4(16.7)
Symmetry of weakness, n (%)	Symmetrical	20(83.3)
	Asymmetrical (mild)	4(16.7)
Pattern of weakness, n (%)	Ascending	19(79.2)
	Descending	5(20.8)
Hughes Score (HS) at onset and at 3 months, n at onset (n at 3 months), (Hughes et al., 1978)	HS 1	0(9)
	HS 2	0(6)
	HS 3	2(2)
	HS 4	21(0)
	HS 5	1(0)
	HS 6	1(0)
Treatment, n (%)	Plasma exchange	17(70.8)
	Intravenous immunoglobulin	1(4.2)
	Both	4(16.7)
	None	2(8.3)

Nerve Conduction Studies: NCS were carried out at inclusion and after 3 months from entry in the study and used for diagnosis of GBS patients. The measurements which were taken were shown in table (2).

Nerve CSA by Ultrasound: Comparison was done between patients at onset and controls regarding CSAs of examined nerves as shown in table (3). Significantly enlarged CSAs were found in almost examined points of peripheral nerves; in median at the level of wrist, mid-forearm, elbow and above elbow, in ulnar at the level of elbow, in radial at level of spiral groove, and in posterior tibial at level of ankle and popliteal fossa. Comparison was done between patients at onset and at follow up with no statistically significant difference could be found regarding CSAs of examined nerves as shown in table (4).

Table (2): Neurophysiological studies of examined nerves in patients' group at onset and during follow up.

Nerve			At onset (n=24)		Follow up (n=17)

CSA is directly correlated in ulnar nerve at wrist with latency of motor fibers, and inversely correlated with amplitude and conduction velocity of sensory fibers. Also, we found CSA inversely correlated with amplitude at popliteal fossa in posterior tibial nerve. No other correlations were found between CSA and electrodiagnostic parameters in examined nerves as shown in table (5).

Table (5): Correlation between CSA (cm^2) and NCS of examined nerves:

CSA	Neurophysiology studies	At onset	
		R	P
Ulnar nerve CSA (cm^2) at wrist	Ulnar nerve (motor) latency (ms) at wrist	0.642	0.005*
	Ulnar nerve (motor) amplitude (mv) at wrist	-0.088	0.738
Ulnar nerve CSA (cm^2) at elbow	Ulnar nerve (motor) amplitude (mv) at elbow	- 0.031	0.905
	Ulnar nerve (motor) conduction velocity (m\s) at elbow	0.034	0.897

	Posterior tibial nerve amplitude (mv) at ankle	-0.308	0.230
Posterior tibial nerve CSA (cm^2) at popliteal fossa	Posterior tibial nerve amplitude (mv) at popliteal fossa	-0.532	0.028*
	Posterior tibial nerve conduction velocity (m\s) at popliteal fossa	-0.109	0.678

* The mean difference is significant at the 0.05 level

Discussion

Nerve ultrasound is an emerging modality for detection of peripheral nerve morphology through measurements of CSA which has been recently studied in different neuropathies. It has several advantages as it is inexpensive and noninvasive method, it also allows the examiner to view the whole length of the nerve quickly and in painless procedure. US of diseased nerves demonstrate changes in CSA, echogenicity and definition of surrounding epineurium[4,8].

We found statistically significant difference regarding CSA between GBS patients at the onset compared to normal controls, which is being larger at GBS patients. This finding was matched with other studies done by Zaidmanet al.[4], Gallardo et al.[6], Grimm et al.[8], and Razali et al.[13].

We found no significant difference regarding CSA between GBS patients at the disease onset when compared with follow up period, despite of clinical improvement. On the other hand, studies done by Almeida et al.[5] and Razaliet al.[13] found gradual reduction in nerve CSAs on serial assessment.

This discrepancy might be due to the longer duration of follow up period in their studies compared to ours. In the current study, US measurement of CSA correlated with some electrodiagnostic parameters but not others. Also, Zaidmanet al.[4], Grimm et al.[6] and Razali et al.[13] found no significant correlations between nerve CSA

and some electrodiagnostic findings of corresponding nerves**.** Watnabe et al.[14], and Di pasquale et al.[15], were found a significant correlation between CSAs and NCS in chronic neuropathies as diabetic neuropathy and chronic inflammatory demyelinating disease, this finding is indistinct at GBS as the nerve affection is patchy; in which segments are affected and others are not.

Conclusion

From this study it could be concluded that ultrasound could be a useful technique which help in early GBS diagnosis through measurement of CSA which is significantly higher in GBS patients at onset when compared to normal subjects in different nerves but no significant difference was found between disease onset and follow up.

More studies are needed to investigate the role of ultrasound in different stages of the disease course to detect changes in nerve morphology in larger sector of patients and to define criteria which could be clinically used in diagnosis.

Effectiveness of Modified Twelve Core Biopsy to the Detection of Prostate Cancer between the Egyptian Patients

Ayman S Moussa[1], Walid Ali Shanaa[2], Mohamed Amer lotfi[3], Khalid Mursi Hammoud[3], Mahmoud Amer Abdulhakim[1]

[1]Assistant Professor, [2]Assistant Lecturer, [3]Professor, Department of Urology, Faculty of Medicine, Cairo University, Giza, Egypt

Abstract

Background: Transrectal ultrasound-guided prostate biopsy is the method of choice for obtaining a conclusive diagnosis of prostate cancer.

Objective: To estimate the efficacy of modified twelve core TRUS prostate biopsy for the detection of prostate cancer among Egyptian patients.

Method: A total of 348 men with elevated PSA and/or abnormal DRE underwent initial TRUS-BX in Alkasr Alainy Hospital, Urology Department, Cairo University. All patients undergoing a modified 12 core biopsy planner in which the 2 medial apical cores on both sides were substituted by 2 cores were taken from the anterior apex, specified as the site at once lateral to the junction of apex and urethra. Site-clearly defined detection and tumor properties were recorded.

Results: Prostate cancer was detected in 122 patients (35.1%). The apical had contained two anterior cores on each side, with cancer detection average 79.7% of all cancers and also achieved the highest rate of unique cancer detection (8.1%).

Conclusion: From our results, it could be noticed that the modifying a level of the quality 12 core biopsy planner by containing the extreme apical cores increment prostate cancer detection on first Transrectal ultrasound-guided biopsies and minimize the potential for misdiagnosis and necessity for repeat biopsy.

Keywords: *Clinically, detection of prostatic, Egyptian of patients, core biopsy.*

Introduction

Clinically, the prostate had contained two lateral lobes, separated by a central sulcus that is palpable when the rectal checking, and a middle lobe, which may be estimated into the bladder in older men. These lobes do not agree to histological known structures in the normal prostate but are often concerning to pathologic magnification of the transition zone laterally and the periurethral glands centrally.[1]

Based on extremist prostatectomy specimens and the position of great prostate cancers, thus, Stamey indicated that the make partial sextant biopsies to be aimed for addition laterally to elevation cancer revelation. Meanwhile, in the late 1990s, many studies observed that a high false-negative average of the sextant biopsy strategy may be due to its absent cancers position in other regions of the prostate **Moussa *et al***.[2]

Extended prostate biopsy (PBx) advanced as a novel premier biopsy strategy after numerous research demonstrated that it considerably increments prostate

cancer (PCa) detection[3]without elevating morbidity or the detection of insignificant cancer[4]

The National Comprehensive Cancer Network (NCCN) has defined EPBx as a sextant cores with at least four additional cores from the lateral peripheral zone as well as biopsies directed to lesions detect on palpation or imaging [5].

Moussa *et al*.[2] studied the important of additional anterior apical core needle biopsy of prostate (Standard 12 cores plus two additional anterior apical cores) concluded that apical core biopsy especially radical apical core elevated prostate cancer awareness on first TRUS-BX and minimize the possibility for misdiagnosis and the necessity for repeat biopsy. Extreme apical sampling increases aggressive prostate cancer detection on initial biopsy, especially in patients with standard risk of prostate cancer[4]

The aim of our study is to estimate the effectiveness of modified twelve cores transrectal ultrasound guided prostate biopsy for detection of prostate cancer among Egyptian patients.

Patients and Method

This is a prospective study to estimate the efficacy of modified twelve core TRUS guided prostate biopsy for the detection of prostate cancer among Egyptian male patients in Kasr Alainy Hospital, Urology Department, Cairo University from January 2017 to February 2019.

A prospective study was conducted on series 384 male patients with suspicious prostate cancer by either elevated PSA or/and abnormal DRE.

They underwent initial modified twelve core TRUS guided prostate biopsy as office-based procedure under local anesthesia.

Inclusion Criteria:

- Patients with elevated total PSA more than 4 ng/ml
- PSA ratio (free/total PSA) ≤10% in total PSA range between (4-10 ng/ml) according to **Leonard *et al.*[6].**
- Abnormal DRE.

They underwent initial modified twelve core TRUS guided prostate biopsy.

Procedure: All the biopsies were taken by one urologist in our institution. In the left lateral decubitus position, DRE was performed prior to the insertion of the probe. Imaging of the gland was then carried out first in a transverse fashion. The right and left seminal vesicles were viewed and followed by the bladder neck, mid gland and apex. After complete transverse imaging, the transducer was configured to provide sagittal imaging. The rights, mid and left aspects of the prostate were visualized. During this part of the examination, particular attention was paid to any regions that were hypo or hyper-echoic when compared to the peripheral zone of the prostate.

Periprostatic local anesthesia was infiltrated by long spinal needle 21 G (10 mL of 1% lidocaine) and biopsy taken by biopsy gun with needle 18 G.

We obtained four cores from the prostate in mid lobar parasagittal planes, halfway between the lateral edge and midline of the prostate gland at the base and mid-gland bilaterally. They essentially correspond to the initial strategy of **Presti[7].** An additional lateral biopsy was performed by obtaining six prostate cores from the lateral apex, mid-gland and base bilaterally at the same level as that of the medial cores. Finally, two cores were taken from the extreme anterior apex located lateral to the junction of apex and urethra making a total of 12 cores **(Figure 1)**. These were taken from extreme tip of apex medially termed as ´very apex` by Shinohara and colleagues[8]**.** This area is the most caudal portion and is often missed during routine biopsy because of its peripheral nature.

We collected the cores in separated containers according to the site of the biopsy and sent to pathology department.

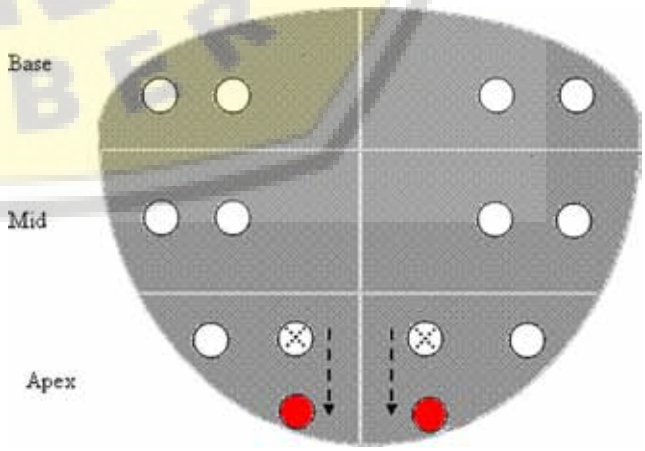

Figure (1): Modified twelve cores biopsy

Statistical Evaluation: All data was analyzed

statistically using SPSS Program Version 15 for Microsoft Windows. *P* value was calculated to check the significance when *P* value was <0.05.

Results

Descriptive data of the whole study population: Table (1) showed that the baseline characteristics of the studied sample. The age of the whole study sample ranged from (50 to 85) years with a mean value of (65. 61 ± 8.43) years. Total Prostatic specific antigen in the whole study sample ranged from 4.0 to 50 ng/ml with a mean value of 14.53 ± 10.66.

The same table observed that the 348 patients who underwent biopsy122 patients were positive for prostate cancer representing (35.1%) of whole patients. Prostatitis was present in 137 patients (39.4%). High grade prostatic intraepithelial neoplasia (HG PIN) was found in 51 patients (14.7%). Atypical small acinar proliferation (ASAP) was noticeable in 53 patients (15.2%)

Comparison between cases with and without prostate cancer as regarding mean of age and PSA: Table (2) shows the higher percentage of prostate cancer among older patients above 66 years which was 45 % compared to 24.4% among those with age below 66 years. The difference was statistically significant in favor of older patients. The odds ratio of finding prostate cancer was noticed as 2.5 times higher in those with older age above 66 years.

Table (1): Descriptive data of the whole study population

Variable	Frequency (Percentage)
Age (years)	65.61±8.43(50-85)
Total PSA ng/ml	14.53±10.66(4-50)
Cancer positive patients	122(35.1%)
Prostatitis/patients	137(39.4%)
HG PIN/patients	51(14.7%)
ASAP/patients	53(15.2%)

The same table showed a higher percentage of prostate cancer among those with total PSA above or equal 10ng\ml which 46.6% was compared to 23.3% among those with total PSA between from 4.0 to10.0 ng/ml. The difference was statistically significant. The odds ratio of developing prostate cancer was remarked as 2.8 times higher in those with PSA was above 10 ng/ml.

Table (2): Comparison between cases with and without prostate cancer as regarding mean of age and PSA

Age	No Cancer	%	Cancer	%	No Cancer	X^2	P	OR 95% CI
<66 years N=168	127	75.6	41	24.4	127	16.4	0.00**	2.5(1.6-4.0)
≥66 years N=180	99	55.0	81	45.0	99			
PSA								
Low PSA <10 ng/ml N=172	132	76.7	40	23.3	132	20.8	0.00**	2.8(1.8-4.5)
High PSA >=10 ng/ml N=176	94	53.4	82	46.6	94			

**P<0.01 highly significant

Comparison cancer positive and negative patients regarding the presence of prostatitis, HG PIN and ASAP: From the results in Table (3) it could be noticed that a higher percentage of prostatitis among patients with no prostate cancer 53.1% compared to 13.9% among patients with prostate cancer and the difference is highly significant statistically. The presence of prostatitis had a protective odds ratio of 0.14. Therefore, the presence of prostatitis was in favor of no cancer.

Cases with PIN had two times higher the risk of having prostate cancer in the same table indicated that the percentage of prostatic intraepithelial neoplasia among prostate cancer patients was 22.1% compared to 10.6% among cases without prostate cancer, thus the difference was statistically significant in favor of prostate cancer patients. The odds ratio of HG PIN was 2.39.

Moreover, presents a higher percentage of ASAP among prostate cancer patients which was 18.9% compared to 13.3% among cases without prostate cancer, but the difference was not statistically significant.

Table (3): Comparison cancer positive and negative patients regarding the presence of prostitutes, PIN and ASAP

Comparison	No cancer			Cancer		
	Infection	HG PIN	ASAP	Infection	HG PIN	ASAP
No	226	226	225	122	122	122
Negative	106	202	196	105	95	99
%	46.9	89.4	86.7	86.1	77.9	81.1

**P<0.01 highly significant

Distribution of positive cancer grade based on Gleason scores, mid-gland, and apical cores with cancer sites cores results: Table (4) found that the pattern and grade of prostate cancer were studied and classified according to Gleason score into low grade (Gleason ≤6), intermediate grade (Gleason=7) and high grade (Gleason >7) and it was found that the commonest grade was high grade in 52 patients (42%) then low grade in 36 patients (29.5%) and the least was intermediate grade in 34 patients (27.9%). From the whole number of patients, 122 of them were positive for prostate cancer with a prevalence rate of 34.1%.

Table (4): Distribution of positive cancer grade based on Gleason scores, mid-gland, and apical cores with cancer sites cores results

Prostate Cancer Grade Based on Gleason Scores N=122	No.	%
Low grade (GLeason≤6)	36	29.5
Intermediate (Gleason=7)	34	27.9
High grade (Gleason>7)	52	42.6
Positive Base, Mid-gland, and Apical cores with cancer N=74		
Base	57	77.0
Mid gland	64	86.5
Apical	59	79.7

Out of these 122 patients who were positive for prostate cancer, only 74 patients had complete data regarding the distribution of positive cores according to the regional sites of the prostate. The percentage of positive cores from the positive base in 57 patients from the total cases was (77%), mid gland cores were positive in 64 patients with percentage (86,5%) and apical cores including the cores from anterior apex were positive in 59 patients with percentage (79.7%)

Distribution and isolate of positive cores among cancer patients: The following Table (5) showed that 14.9% of the 74 patients with prostate cancer had only one region site positive cores. 27% of those patients had two regional site positive cores while 58.1% of the patients had the three regional site positive cores. Whereas, in a number of 11 patients of the 74 prostate cancer patients with percentage (14%), the prostate cancer detected exclusively in only one regional site with the apical cores including anterior apex cores had the highest detection rate among this group of patients included 6 patients (8.1%) followed by mid gland in 3 patients (4.1%) and lastly base in two patients (2.7%).

Table (5): Distribution of Positive Cores among Cancer Patients

N=74	No.	%
One site core positive	11	14.9
Two sites core positive	20	27.0
Three sites core positive	43	58.1
Apical only positive	6	8.1
Mid gland only positive	3	4.2
Base only positive	2	2.7

Discussion

In the current study, the prevalence of prostate cancer was 35.1%, which was lower than Western countries and had higher percentage in patients above 66 years old and with high serum PSA 46.6% in patients with PSA above was 10 ng/ml compared to 23% in PSA between from 4 to10 ng/ml) and most of the prostate cancer with high grade pattern 42.6%. **Mosli*et al.*** [10] studied the incidence of prostatic a malignant tumor formed from glandular structures in epithelial tissue in patients accepted to King Abdul–Aziz University Hospital observed that the prostate cancer was revealed in 28.5% of patients with total PSA > 4 ng/ml, which is sawing lower than the happened for their patients average age 68 years. Another research parallels the age-adjusted serum level of total PSA of the Arabic people with that of the USA and the Japanese people. They observed that the USA whites direct to have the greatest total PSA, followed by the Japanese people and the lowest PSA level was present in the Arabic people[11].

There are many studies raise the importance of the anterior apical core prostate biopsy for increasing the cancer detection rate. **Presti*et al.*** [12] examined a dataset of 2299 patients who had experienced a 12-core systematic biopsy scheme by 167 group of people- based urologists. All patients were initial biopsy, and the overall cancer detection average was 44%. These great series explain the reproducibility of made larger biopsy schemes in the hands of practicing urologists.

In their study, **Moussa *et al.*** [2] detected prostate cancers in 86 patients (47.5%). The results showed that the apical cores (3 on each side) were had contained the greatest cancer detection average 73.6% of all cancers, and as well as radical front apical cores was one on each side, was contained the greatest average of cancer detection (P value= .011). It could be concluded that the apical cores, especially the radical frontal apical cores, increment prostate cancer detection on TRUS-BX and minimize the possibility of misdiagnosis and the necessity for repeat biopsy.

In our study the highest detection rate for prostate cancer was in mid-gland core in 64 patients (86.5%) followed by apical cores in 59 patients (79,7%) but the apical cores including the extreme anterior cores achieved the highest unique cancer detection rate. **Babaian*et al.*** [13] estimated an 11-core biopsy strategy in 362 patients, containing 85 patients (23%) who underwent the initial biopsy. The biopsy planner involved cores from a level of the quality sextant, bilateral anterior horn, bilateral transition region, and midline. The cancer detection average for patients who underwent the first biopsy was 34%, and nine cancers were uniquely specified by non-sextant sites (increasing CDR by 31%). of the cancers specified uniquely by cores from non-sextant sites, seven were specified by anterior-horn biopsies and two by transition-region biopsies.

Conclusion

From the obviously results it could be concluded that the prevalence of prostate cancer among the Egyptian population was 34% with a mean age of 66 years and with more detection rate among patients with total PSA more than 10 ng/ml with high-grade pattern in 42,6%. The cancer detection rate in apical cores including cores from extreme anterior in both sides was 79,7 % and exclusive only site with cancer in 8,1%, so we recommend this modified twelve cores biopsy to be the standard for initial TRUS guided prostate biopsy for the screening of prostate cancer

Epidemiological Study of Cleft Lip and Palate in Al-Samawa City (South of Iraq)

Osamah Mohammed Aldaghir[1], Hayder Saad Hanfoosh[2], Samer Salim Jaafer[3]

[1]Lecturer, [2]Assistant Professor, [3]Assistant Lecturer, College of Dentisry, Uneversity of Almuthanna. Iraq

Abstract

Purpose: The aim of this retrospective study was to evaluate the epidemiology of CLP among population in the south of Iraq, and to assess the risk factors to its development

Materials and Method: The collected sample from 2010 to 2014, consists of 80 patients (47 male and 33 female) with different type of cleft lip and palate, their ages range from 1 week to 14 years old. they were evaluated well for the gender, site, type based on McCarthy (1990) who classified clefts into unilateral or bilateral, Finally the cause (genetic or acquired), and the associated other congenital anomalies

Results: We found that approximately 2 infants per 1000 live births were affected. The affected males were 47 (nearly 59 %), while the affected females were 33 (41%) of the sample. The unilateral clefts lip with or without cleft palate were 49 cases “nearly 75%” of the cleft lip cases The bilateral clefts lip with or without cleft palate were 16 “nearly 25%” of the cleft lip cases. The associated combined anomalies were found in 11 patients “nearly14%”

Conclusion: The distribution of the cleft lip and \ or cleft palate in the south of Iraq is not far from that worldwide but its main causes is somewhat different as the genetic causes implicated to be the main risk factor.

Keywords: *Cleft lip; cleft palate; congenital anomalies; epidemiology; south of Iraq***.**

Introduction

One of the commonest orofacial malformations that occur during fetal development is the cleft lip with or without cleft palate [1]. Many etiological factors are involved in its appearance which could be genetically related or developmentally related[2,3]

Psychological and social complications can affect the parents and their children that make early detection and management is mandatory[4,5,6].

Our aim of this study was to evaluate the epidemiology of CLP among population in the south of Iraq, and to assess the risk factors to its development.

Materials and Method

The Sample: The sample of this prospective study includes patients who were born and registered in Al-Samawa hospital for obstetrics and gynecology (the main hospital in Al-Samawa city), so the patients were belong to different areas (rural and urban).

The collected sample from 2010 to 2014, consists of 80 patients (47 male and 33 female) with different type of cleft lip and palate, their ages range from 1 week to 14 years old.

During period of study the number of live births in the Maternal and Pediatric Hospital was recorded which was 40500 live birth.

The examined patients were all included in this study, and they were evaluated well for the gender, site, type based on McCarthy (1990) who classified clefts into unilateral or bilateral, Finally the cause (genetic or acquired), and the associated other congenital anomalies especially cardiac and ophthalmological anomalies by

consulting cardiologists and ophthalmologists are also recorded.

Results

In this study, we found that 80 patients out of 40500 live births were born with cleft lip\and or cleft palate, so their percentage was 0.19%, that is mean approximately 2 infants per 1000 live births were affected.

The gender distribution was as follows:

1. The affected males were 47 (nearly 59 %) of the sample, of them 31 patients (nearly 39 %) had cleft lip and palate, 11 patients (about 14%) had cleft lip only, while the remaining 5 patients (6%) were born with cleft palate only.
2. The affected females were 33 (41%) of the sample, of them 20 patients (about 25%) had cleft lip and palate, 10 patients (about 12 %) had cleft palate only, while the remaining 3 patients (about 4%) were born with cleft lip only. Table 1

The percentage of the site of the clefts were as follows:

1. The unilateral clefts lip with or without cleft palate were 49 cases "nearly 75%" of the cleft lip cases (39 left sided, and 10 right sided) .
2. The bilateral clefts lip with or without cleft palate were 16 "nearly 25%" of the cleft lip cases . Table 2

The predisposing factors for development of the anomaly was as follows:

1. The relativity of parents\ 65 cleft patients "nearly 81%" were born to parents who are consanguine.
2. The developmental factors\ 3 mothers "nearly 4%" who born a child with cleft reported that they had a flu like illness during the first trimester, and 5 mothers "nearly 6%" reported a dietary deficiency during period of pregnancy.
3. The housing area\71 cases "nearly 89%" had been came from rural areas, while only 9 cases "nearly 11%" from urban areas.

Associated Congenital Anomalies: The associated combined anomalies were found in 11 patients "nearly14%" (5 with cardiac anomalies, 2 with visual impairment, 2 with congenital cerebral palsy, and 2 with thoracic cage anomaly "pigeon chest").

Table 1: Gender distribution of different types of the clefts & its statistical significance.

Type of the cleft	Male		Female	
	No.	%	No.	%
CLP	31	39	20	25
CL	11	14	3	4
CP	5	6	10	12
Total	47	59	33	41

CLP: cleft lip and palate, CL: cleft lip, CP: cleft palate

Table 2: Site distribution of the cleft lip & its statistical significance.

Side of the cleft	No.	%
Left	39	60
Right	10	15
Bilateral	16	25

Discussion

The Sample: In this prospective study, I found that approximately 2 infants per 1000 live births were affected with cleft lip and \or palate, which is not so far from that in adjacent areas like in Iran (2.14 per 1000 live births)[7].

The Gender Distribution: The percentage of cleft lip and palate between males (39%) and females (25%) was not so different, however, I found that the incidence of cleft lip only was greater in males (14%), while the incidence of cleft palate only was greater in females (12%), these results were not away from that of another study which was done in Baghdad (the capital of Iraq) by Al-Zubaidee et al[8]

The percentage of the site of the clefts: It was found that the unilateral cleft (75%) was more common than bilateral, and the left sided clefts (60%) were significantly more common than that on the right, all these findings are in acceptance with the universal agreement.[7,8,9]

The Predisposing Factors: A high percentage (81%) of the parents who had children with CL &\or CP) were relatives, and most of them (89%) came from rural areas, this is due to the increasing number of marriages between relatives in those areas in regards to the urban

people, so this reflected that the genetic causes were the main cause of CLP development in the south of Iraq, however environmental causes like a dietary deficiency also implicated, because the rural people are away from health centers which are responsible for pregnancy care .these findings are in agreement with Carinci F, Rullo R et al[10], and Ingalls et al.[11]

Associated Congenital Anomalies: In this study we found that the cardiac anomalies are the most common associated congenital anomalies, so it is mandatory to send every child with cleft lip and\ or cleft palate for echocardiography and chest x-ray to exclude anomlies, these findings also were stated by Shin et al[12],Greene[13], and Abyhom[14].

Conclusions

From this study we can conclude that the distribution of the cleft lip and/or cleft palate in the south of Iraq is not far from that worldwide but its main causes is somewhat different as the genetic causes implicated to be the main risk factor.

The investigations for exclusion of congenital anomalies must be done as early as possible especially those for heart anomalies, to avoid intraoperative complications

Association between Iris in and Obesity

Leana Alaa Abbas[1], Saad Merzah Hussein[1], Wathiq Essam Hameed[1]

[1]College of Medicine, University of Babylon, Iraq

Abstract

Objective: To observe the relationship between serum Irisin and obesity. Background: One of the top worldwide health problems is obesity. Many causes have been implicated for developing obesity such as: excessive food intake, lack of physical activity, genetic susceptibility, endocrine disorders, medications, or mental disorder.

Material and Method: One hundred and five individuals were participated in this study visiting Al-Imam Al-Sadiq Teaching Hospital from October 2017 to June 2018. A 50 normal non-obese, and 55 obese. They were classified according to body mass index after measuring their weight, height. Blood and data were collected from patients and control to detected Irisin.

Results: The highest percentage of obese patients were female, the highest percentage of obesity was recorded among 20-30 age group, the majority of the obese patients were from urban areas, and largest group of obese patients were unemployed. Regarding investigation: Irisin, there is significant difference ($p \leq 0.05$) between case and control for Irisin. There is also a significant positive correlation between irisin and body mass index (p value$\leq$0.05; r = 0.44), and with the waist circumference (p value $\leq$0.05;r = 0.407). Conclusion: serum irisin levels were higher in obese patients than in control. Moreover, serum irisin levels were correlated positively with anthropometric markers of obesity (BMI, Waist Circumference).

Keywords: *Obesity, Irisin, Body Mass Index, Waist Circumference.*

Introduction

Obesity is "a chronic, relapsing, multifactorial, neurobehavioral disease, where there is an increase in body fat adversely effects on adipose tissue function and physical forces of fat mass, resulting in abnormal biomechanical, metabolic and psychosocial health consequences", it is more common in women [1-3].

There are many types of obesity depending on where fat cells are stored. Abdominal obesity (excessive accumulation of fat cell in adipose tissue of the abdomen) is associated more strongly with meta-inflammation[4].

Irisin is a plasma myokine/adipokine that is produced by the proteolytic cleavage of fibronectin type III domain containing 5 (FNDC5) [5].

There are many reports of the positive, negative and no correlations between serum irisin and body mass index (BMI) [6-9].

The aim of This Study is To observe the relationship between serum Irisin and obesity

Materials and Method

Subjects: A case-control study was conducted in the obesity unit in Al-Imam Al-Sadiq Teaching Hospital at Babylon Governorate/Iraq, from October 2017 to June 2018.

Inclusion Criteria: A convenient sample of one-hundred five individuals were included in this study (55 obese and 50 control) according to body mass

index, with age range from 18 to 51 years old. All individuals subjected to the same clinical examinations and biochemical tests. The obese persons were taken from the obesity unit in the hospital while the control group individuals were friends, medical staff, medical students, and relative to the patients. Informed consent must be taken from all people.

Exclusion Criteria:

1. Free of significant medical illnesses {diabetes mellitus (DM) (type I or II), cardiac disease, hypertension (HTN), hypothyroidism, poly cystic ovarian syndrome (PCOS), acromegaly, and any congenital abnormalities} that known to impact body weight.
2. History of drugs administration that cause obesity or increase in body weight such as Antiepileptic drugs, anti-Diabetic drugs, Oral contraceptive pills, steroids and Chemotherapy.
3. Post-menopause women.
4. Pregnant women.

General History: Socio-demographic traits such as: age, gender, occupation, educational level, residency. Past medical history: thyroid disease (hyper: tremor, heat intolerance, palpitation; hypo: cold intolerance, previous unexplained obesity, etc.).Past surgical history: history of bariatric surgery, gynecological history: menstruation, fertility, pregnancy history, and dietary history.

General Examinations:

Weight Measurement: Patient is weighed with minimum clothes and bared feet by digital scale with 0.1 kg as degree of error[10].

Anthropometric Measurements: Height: Is measured by graded scale firmly fixed on the wall when participant is standing against the wall while feet are bared and the legs are held close to each other, no bending, the shoulders are straight in parallel line, the height is measured from the ground to the top of the head [11].

Waist Circumference: Is measured by flexible tape measure graded to 0.1cm at the midline between the last rib and the upper part of iliac bone [12].

Body mass index (BMI): Is calculated by dividing the weight in kilograms by the square of the height in meter[13].

Results

Socio-Demographic Characteristics of Study Groups: The highest percentage of obese patients (89.09%) were female as shown in figure 1:

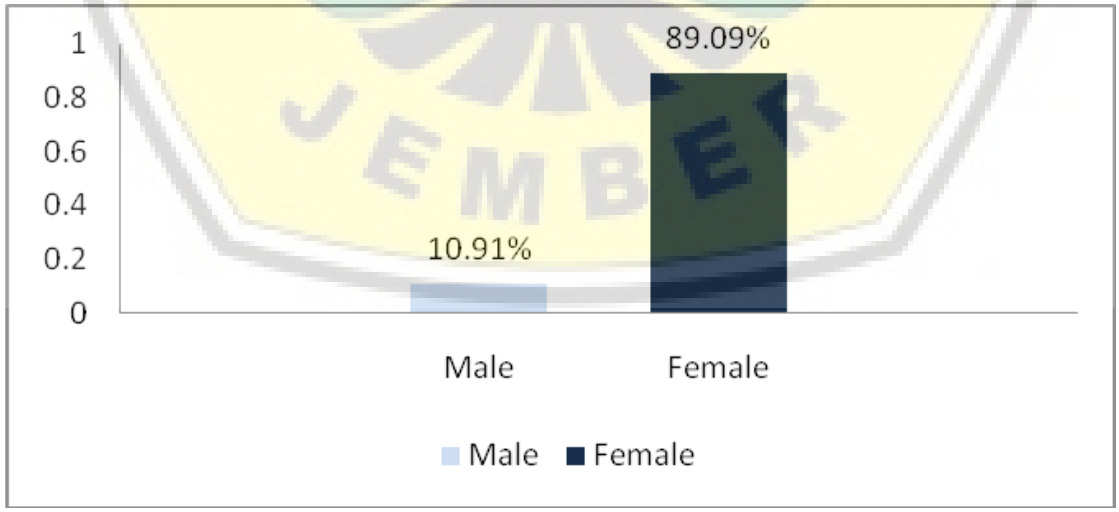

Figure 1: Distribution of obese patients according to the gender

The highest percentage for obesity was recorded among 20-30 age group, while the lowest percentage for obesity was recorded below 20 years old as shown in Figure 2.

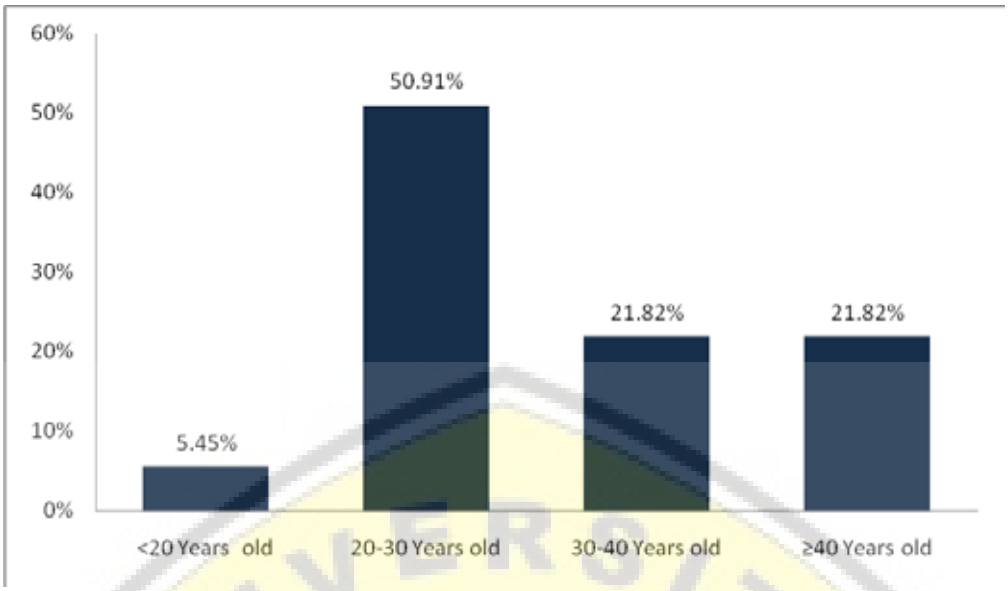

Figure 2: Distribution of obese patients according to age groups.

The majority of the obese patients (63.64%) were from urban areas. Minority of obese patients were from rural area as shown in figure 3.

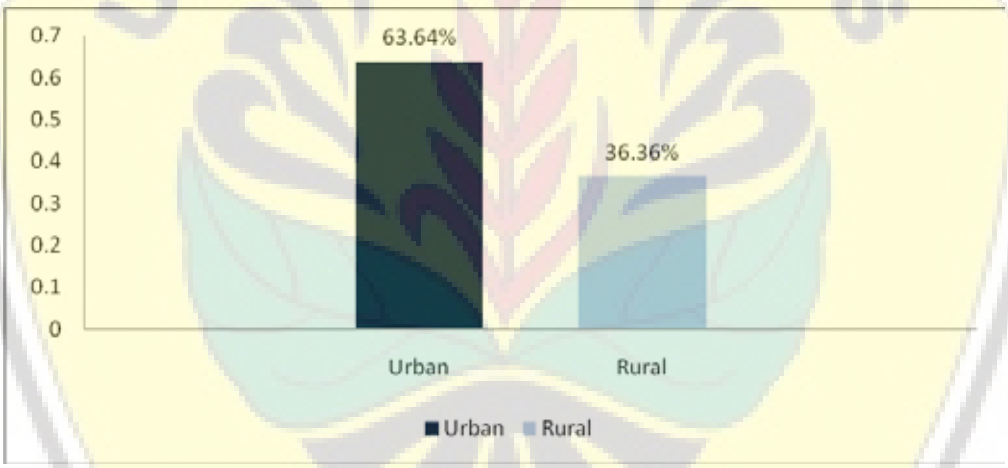

Figure 3: Distribution of obese patients according to residence.

Largest group of obese patients were unemployed as shown in figure 4.

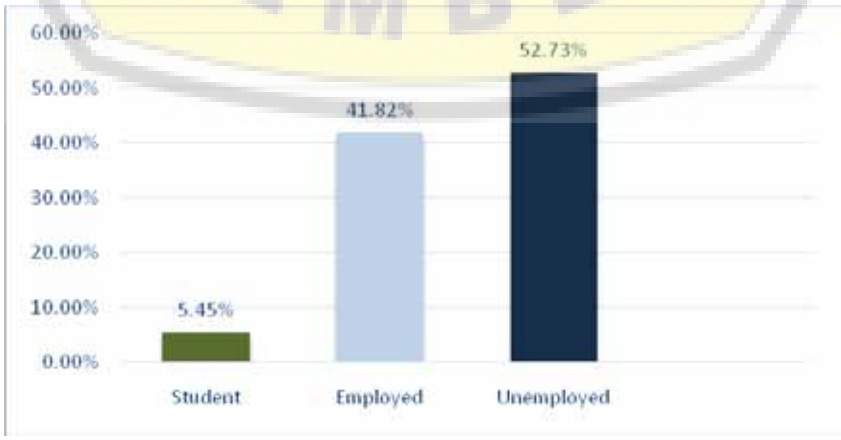

Figure 4: Distribution of obese patients according to occupation.

Figure 5 shows mean differences of irisin (ng/ml) for control and obese patients. There were significant differences between means of irisin for both study groups. **(t=9.435, P= <0.001*).**

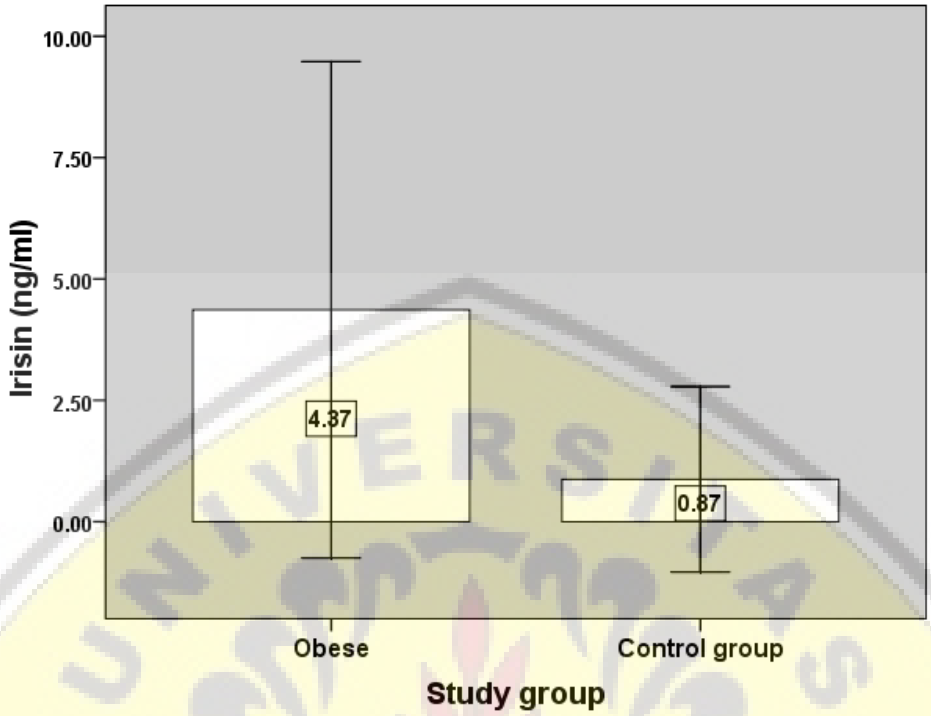

Figure 5: Meandifferences of Irisin (ng/ml) according to study groups

Figure 6 shows the correlation between Irisin (ng/ml) and body mass index (kg/m^2) among obese patients. There was significant positive correlation between irisin and BMI(p value≤0.05). **(r = 0.441, P = 0.002*).**

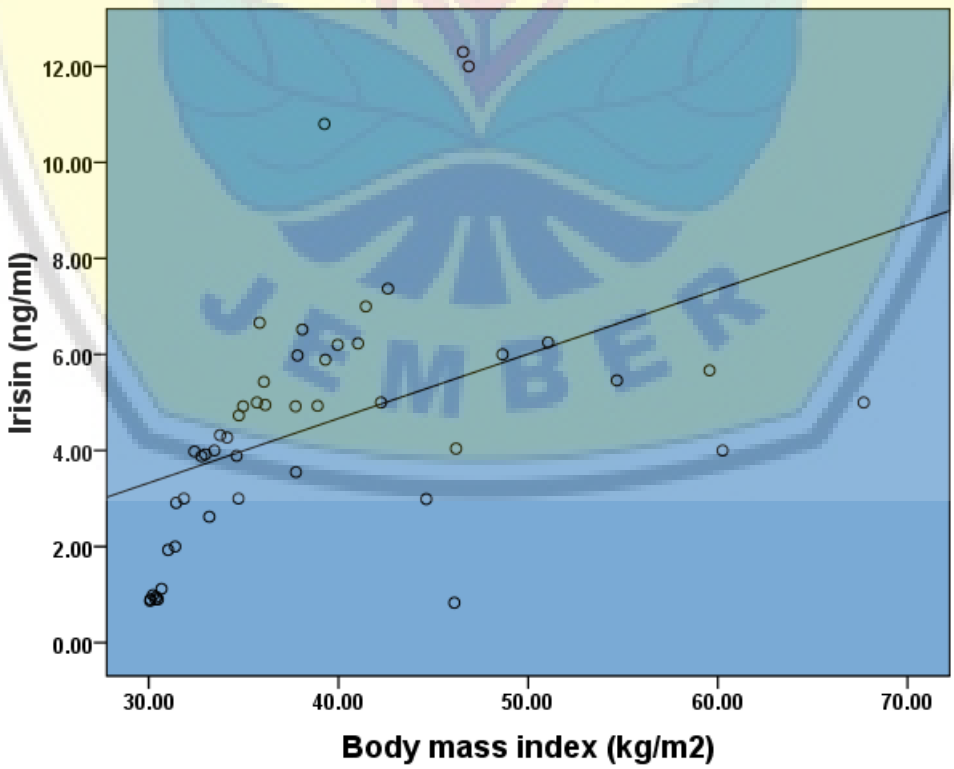

Figure 6: The Correlation between Irisin (ng/ml) and BMI among Obese patients (Correlation is significant at the 0.05; r:correlation coefficient)

Figure 7 shows the correlation between Irisin (ng/ml) and waist circumference (cm) among obese patients. There was significant positive correlation between irisin and waist circumference (p value≤0.05). **(r = 0.407, P = 0.004*).**

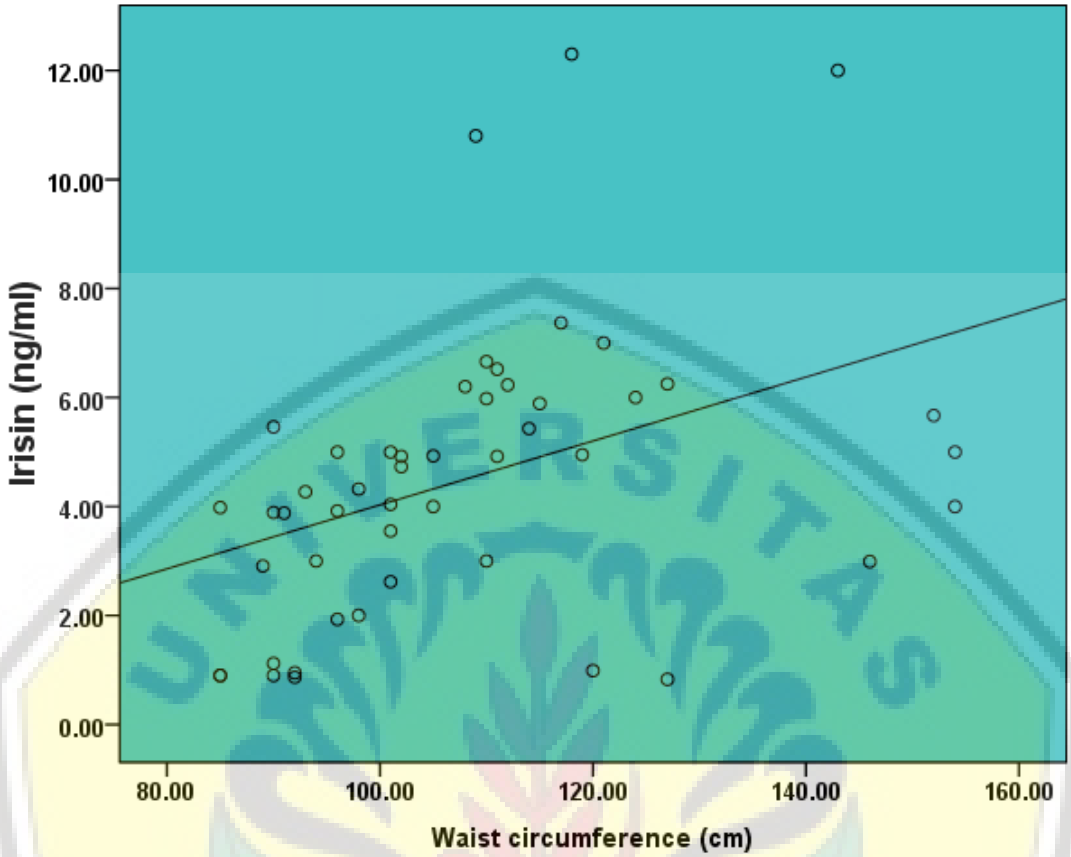

Figure 7: The correlation between Irisin (ng/ml) and WC among obese patients (Correlation is significant at the 0.05; r:correlation coefficient).

Discussion

Regarding to the gender of obese patients shows in figure 1, the highest percentage of obese patients (89.09%) were female. This result agree with findings of other researchers [14-20]. The suggested reason for this result is presence of Traditional/cultural restrictions in lifestyle of women in Iraq are one source for increased rates of obesity among females than males, females have limited access to sports and exercise activities, also multiple pregnancies is an important factor as women gain 4.5 kg or more in one year postpartum, due to a combination of factors such as gestational weight gain, decreased physical activity, and increased food intake.

Regarding the age of obese patients shows in Figure 2 the greatest increase of obesity was seen among 20-30 age group and this result agree with the findings of[21-24], this may be due to sedentary life-style and dietary habits. Also young adult people who live in countries making the socioeconomic shift, are particularly affected by the social and environmental factors such as financial independence, the easy availability of 'ready to eat' food stuffs, the increasing numbers of fast food chain shops, which are all part of adopting western life culture.

Regarding the residence of obese patients shows in Figure 3, the majority of the obese patients (63.64%) were from urban areas, this result agree with [25-29]. Urban populations are more exposed to a sedentary lifestyle and the high-fat fast food consumption are common, and it is clear that those populations are at a higher risk of developing obesity compared with rural populations, which have a higher level of physical activity such as fishing and agricultural work.

Figure 4 showed distribution of obese patients according to occupation. Largest group of obese patients

were unemployed, this result agree with the findings of [29-31]. Unemployment is more strongly associated with adiposity outcomes. Also, psychosocial stress and financial restriction associated with unemployment could have heterogeneous effects on energy balance .

Figure 5 shows mean differences of irisin (ng/ml) for control and obese patients. There is significant difference between control and obese patients (p value ≤0.05), the resulted data shows higher level of Irisin in obese patients compared with control, These findings confirmed the results of a previous study which demonstrated that obese patients had higher circulating levels of irisin than normal weight individuals [9, 32,33], in contrast with other studies that found lower irisin levels in obese patients [34].

Figure 6 shows the correlation between Irisin (ng/ml) and body mass index (kg/m^2) among obese patients. There is significant positive correlation between irisin and BMI(p value≤0.05). (r = 0.441, P = 0.002), in accordance with our findings, several studies have revealed a positive correlation between serum irisin levels and BMI[6,32,33,35,36]. Contrastingly, some studies found a significant negative correlation between circulating irisin and BMI [34,37]. Moreover, one study reported that irisin was not related to BMI[38].

Figure 7 shows the correlation between Irisin (ng/ml) and waist circumference (cm) among obese patients. There is significant positive correlation between irisin and waist circumference (p value≤0.05). (r = 0.407, P = 0.004).This result agree with (6,36), while disagree with[38].

Conclusion

Serum Irisin levels are higher in obese than in non-obese people.

Recommendations:

1. A community-based multiple prevention and intervention strategies should be implemented to combat with increasing level of obesity.
2. Study the gene expression of irisin, leptin, ghrelin associated with obesity.
3. We may push for the increasing medicalization of obesity.
5. Routine cardiac checkup for obese patients by a cardiologist doctor.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Conflict of Interest: The authors have no conflict of interest.

Abstract

Fifty subfertility couples were involved in the present study during their attendance at the fertility clinic at Al-Sadder teaching hospital in Al-Najaf/Iraq throughout a period from January 2018 to January 2019 to undergo intracytoplasmic sperm injection (ICSI). Details history and physical examination were done for every subject participated in this study. Fertilization rate (FR) was calculated as percentage transformation of microinjected oocytes into two pronuclei. A categorical variable of FR defined based on 50% FR grouped couples; Group I with FR>50% and Group II with FR>50%. The objective of this study was to investigate the influence of fertilization rate on ICSI outcome and pregnancy rate for unexplained subfertile couples. Main results of this study revealed that there was a significant difference ($p<0.05$) in ICSI outcome and pregnancy rate between different study groups. With increasing fertilization rate, there was an increase in the ICSI outcome and the pregnancy rate. It was concluded that increased fertilization rate have a positive impact on the ICSI outcome and pregnancy rate for unexplained subfertile couples.

Keywords: *Intracytoplasmic sperm injection, Fertilization, Fertilization rate.*

Introduction

Infertility could be defined as the couples inability to achieve spontaneous conception after one year or more of a regular, unprotected sexual relationship [(1)]. Infertility is a growing concern affecting globally up to 15% of couples trying to conceive, and it represents a source of social and psychological suffering for both men and women and can place high pressure on the relationship within the couples[(2)]. Fortunately, progresses in the assistive reproducing technologies (ART) have assists many subfertile couples to achieve conception[(3)]. In Vitro Fertilization (IVF) is a well-established procedure as a treatment of various types of infertility, including tubal obstruction, endometriosis, idiopathic infertility and some cases of mild male infertility. However, those couples suffering from severe male factor infertility represent the leading cause of failed fertilization in IVF[(4)]. The need for a more efficient procedure to achieve normal fertilization ended with the development of ICSI, where a single viable sperm was introduced directly into the ooplasm [(5)]. The first human pregnancy and live birth using this technique were achieved in 1992. Since then, ICSI has become the common treatment of choice for couples presenting with male infertility[(6)]. Fertilization rate (FR) is the percentage of the transformation of microinjected oocytes into two pronuclei [(7)]. The implantation rate (IR); the number of pregnancies per embryo transferred, has been reported to

vary from 10% to 40% in different clinics. Fertilization process involves that, the ovulated or retrieved oocyte is activated by sperm entry either by normal conception in vivo or artificially with ICSI. Events happen during fertilization include sperm-oocyte membrane fusion, then polar body extrusion and completion of the second meiotic division[8]. The first week of preimplantation development starts from fertilization and continue up to blastocyst hatching. This involves repeated mitotic division of zygote in the tubes and uterus before the blastocyst hatches and implants in the endometrial cavity on day 6 or 7[9].

The most important morphological criteria to evaluate cleaved embryos in vitro are blastomere size and shape, whether even or not, fragmentation and multinucleation[10]. Nuclear structure, especially of nucleoli, change after embryonic genome expression between the 4-cell and 8-cell stages, where compact nucleoli in early embryos become progressively reticulated in later embryos [11]. Failure of treatment after ICSI a to a long list of factors which vary depending on the cause of infertility. In 25% of the cases, the aetiology of infertility cannot be found. This unexplained infertility is described with normal semen counts together with optimal ovulatory functions, presence of patent tubes and a normal uterine cavity [12]. It has been observed that failure of fertilization and cleavage is more likely to occur in couples with unexplained infertility as compared to tubal factor infertility, and male sperm problems [13].

Materials and Method

Patients: A total of fifty subfertile couples who approach the clinic of fertility centre at Al-Sadder teaching hospital in Al-Najaf/Iraq for their inability to conceive and undergoing ICSI were included in this study, throughout a period from January 2018 to January 2019. Couples with unexplained infertility for more than two years with female's age ranging from 20 till 35 years were included. Details history and physical examination were done for every subject participated in this study. Subfertility due to male factor and females with polycystic ovaries, endometriosis, and endocrine abnormalities were excluded from the study. Fertilization rate (FR) was calculated as percentage transformation of microinjected oocytes into two pronuclei. A categorical variable of FR defined on the basis of 50% FR grouped couples; Group I with FR ≤ 50% and Group II with FR >50%.

Sperm preparation for ICSI: Semen analysis and preparing, damage to sperm must be minimized by avoiding large fluctuations in temperature and unnecessary centrifugation[14].

Intracytoplasmic sperm injection (ICSI): All-female partners were subjected to controlled ovarian hyperstimulation with different protocols, including long agonist, short agonist, and antagonist programs. Ovulation was induced by intramuscular injection of 10,000 IU of human chorionic gonadotrophin. Oocyte retrieval procedure was performed under ultrasound guidance at about 36 hr. after triggering. The oocytes were denuded by hyaluronidase enzyme and the mechanical way by repeated aspiration through a sequence of denuding pipettes. Then the oocytes were washed with the culture medium, and the maturity of oocytes was assessed.

Oocyte Culture and Evaluation of fertilization: The normal standardized routine method was used for all patients 16-18 hours after injection oocytes were inspected for fertilization (finding of two pronuclei and two polar bodies). The fertilization rate was calculated from the number of oocytes normally fertilized divided by the number of injected oocytes. Subsequent evaluation of the embryo quality depended on blastomere number, shape, equality, mononucleated and proportion of fragmentation. Embryos were incubated individually in drops and transferred daily to fresh cleavage medium. Embryos were classified as 'good quality' if they were at the four-cell stage at forty-eight hr. after injection or at the six- to the eight-cell stage, seventy-two hr. after injection with even-sized blastomeres and little or no fragmentation [15].

Pregnancy Evaluation: In this study, pregnancy was reported as positive when serum hCG (IU/mL) concentrations were more than 10 IU/mL on day 10 post-transfer, and clinical pregnancy was confirmed by the presence of cardiac activity on transvaginal ultrasound scan (TVS) two weeks afterwards [16].

Results

In this study, we evaluate the impact of fertilization rate on ICSI outcome and pregnancy rate for unexplained subfertile couples.

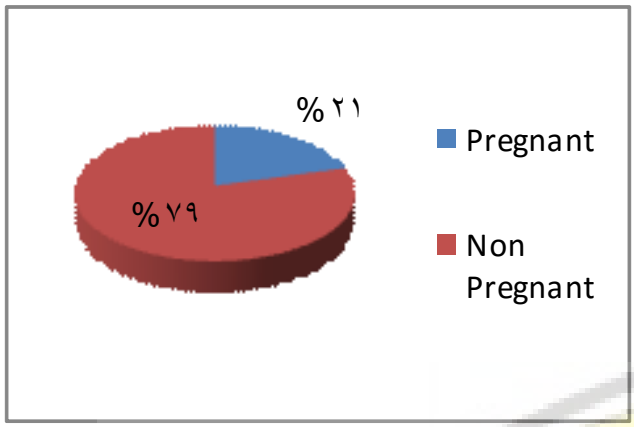

Figure 1: Distribution of patients according to the pregnancy rate (PR).

Figure 2: shows the pregnancy rate among different studied groups. The clinical PR was 15.9% in group I and 29.4% in group II. Thus, a higher rate was achieved in group II.

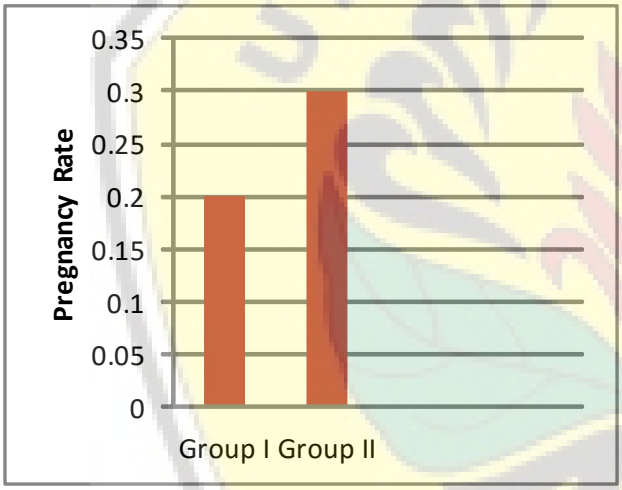

Figure 2: Pregnancy rate among different studied groups.

Table-1 shows that Group II had higher basal E2, LH and FSH levels than Group I, but the results were not significant.

Table 1: Hormonal profile of the studied groups

Hormone	FR		P-value
	<50%	>50%	
Basel E2 (pg/ml)	38.41	39.57	0.783
E2 at the day of HCG injection (pg/ml)	1768.32	1693.88	0.785
Basel FSH (Miu/ml)	5.41	5.48	0.916
Basel LH (Miu/ml)	3.15	3.33	0.688

Table 2: shows that Group II had higher ICSI outcomes than Group I, there was a significant difference.

Table 2: ICSI outcomes of the studied groups.

ICSI Outcome	FR		P-value
	<50%	>50%	
No. of follicles	8.35	9.73	0.304
No. of retrieved oocytes	5.85	6.77	0.438
Good injected oocyte	5.20	5.77	0.545
2PN	1.80	5.10	0.00
No. of embryos	1.75	4.83	0.00
Grade I embryo	0.8	1.5	0.67
Grade II embryo	0.65	2.4	0.002
No. of embryos transferred	1.75	3.87	0.00
Cleavage rate	83%	93%	0.289

Discussion

The introduction of intracytoplasmic sperm injection (ICSI) in 1992, a technique of in-vitro fertilization using direct insertion of a single sperm into an egg, offered the ability to bypass even some of the most severe etiologies of male subfertility[4]. ICSI procedure need a single life sperm with ability to activate oocyte and form pronuclei is necessary but morphology, motility and acrosome status not important [15]. It is documented that fertilization of oocytes involves a complex series of events requires growth, development and cytoplasmic maturation of oocytes microinjected with spermatozoa. Implantation of the human embryo is a well co-ordinated sequenced event of apposition and adhesion of the invading blastocyst in the endometrial bed during the window of implantation[17]. The sensitivity of antral follicles to gonadotropic drugs, response to stimulation, oocyte maturity, fertilization, embryo quality and endometrial thickness, all contribute to the magnitude of success rates of ART. In all procedures, failure of fertilization is the stage which stops the process and wipes the hopes and expectations of the infertile couples. The problem is intensified more in the couples to whom the reproductive endocrinologists have no true explanation of the cause of infertility. It is established that low FR results in poor IR and pregnancy outcome in comparison to patients with greater FR[18]. During ICSI, a number of oocytes estimated by TVS as preovulatory follicle count (PFC) is the strongest predictor of number of oocytes obtained during oocyte pick up. In the present study, the oocytes number and basal FSH was high in group

II. E2 produced during the follicular phase of female reproductive cycle improves endometrial receptivity for implantation of the blastocyst. A good number of oocytes and high E2 measured on the day of hCG administration reflects response and pregnancy outcome that has been subjecting of debate by several researchers [19]. In a previous study, it is reported that females with higher peak E2 had more significant number of retrieved, mature and fertilized oocytes with increased FR and IR [17]. In this study, peak E2 gives a positive predictor of FR in patients of unexplained infertility. Our results in this study show that the quality of the embryos at the time of ET has a critical effect on the outcome of ICSI, as was the case with conventional IVF.

Total oocyte retrieved, PN, grade II embryo, the total number of embryos, and the number of ET were significantly higher in pregnant women when compared with non-pregnant women. These results agreed with Van Loendersloot and his co-workers in 2014 who found a direct relationship between the increasing number of oocytes retrieved, ET, embryo quality and pregnancy rate after ART [20]. Also, he discovered that pregnancy chances had a significant association with ICSI parameters[20].

Cai and his co-workers (2011) found that the total number of grade I and II embryos was a superior predictor for ART success [21]. Also, they established that embryonic parameters, including a total number of grade I & II embryos and the total number of embryos, ordered as the first most important and second most important predictors for ART success. These results recommend that the total number of embryos give additional information to predict ART success if there was a lack in the determination of the total number of good-quality embryos. It may be a substitution marker for hormonal factors and may work through the uterine receptivity[22].

It is clear that in ICSI, different sperm indices do not affect the fertilization rate, PR, or the outcome of pregnancy as long as a morphologically well-shaped motile sperm is used for injection[23]. Although poor-quality embryos failed to demonstrate the same PR as those derived from mature oocytes, the cause was not the quality of the sperm, but the quality of the oocyte and particularly the maturity of the cytoplasm. In general, the ICSI fertilization rate is lower than expected despite the mechanical injection of one sperm into a mature oocyte, possibly because sperm that is selected may have defects in their DNA [24]. That is to say ICSI procedure bypass the natural selective process although the most normal-appearing and motile spermatozoa are selected there is always a small percentage of sperm used in in vitro fertilization (IVF)/ICSI that contains varying degrees of DNA damage and due to the high apoptotic activity during development into a blastocyst the chance of a successful ongoing pregnancy is significantly low [24].

Conclusion

It was concluded that increased fertilization rate have a positive impact on the ICSI outcome and pregnancy rate for unexplained subfertile couples.

Antifungal Activity of Mixture Eugenia Aromaticum and Thymus Vulgaris Essential Oils Against Candida Albicans Clinical Strains in Al-Muthanna Province

Dhay A. Azeez

Department of Biology, Faculty of Science university of Al-Muthanna, Al-Muthanna, Iraq

Abstract

The aim of the study was to investigate the antifungal properties of plant essential oils (EOs extracted from Mixture of Eugenia aromaticum and Thymus vulgaris -M-ET) against Candida albicansclinical strains. The antifungal activity of the plant EOs were determined by broth microdilution and microtiter assays. The results indicated a good antifungal activity of M-ET EOs against C. albicans strains. The overall antifungal results demonstrated that the investigated plant EOs represent promising approaches to cope with the emerging antifungal resistance.

Keywords: *EOs, antifungal activity, Candida albicans.*

Introduction

The novel antibiotic resistance and recurrence of fungal infections linked the attention of scientists to conduct intensive studies about this problem. It has been indicated that immunodeficiency disease (AIDs), diabetes and leukemia are associated with fungal re-infections[7].

Candidiasis is a common opportunistic diseases of skin and oral cavity caused by Candida species. The most common and worldwide distributed one is C. albicans[13], this pathogenic yeast owns several virulence factors involving; adherence, germ tube formation and enzymes production, such as phospholipase[16]. Candidaisis is a common recurrent infection due to the presence of the causative agent, C. albicans mainly, as a commensal fungi in oral cavity, vaginal and digestive system[9], Getting infected with human immunodeficiency virus (HIV), diabetes, Leukemia or administration of broad spectrum antibiotics may promotes converting the normal flora to opportunistic microbes[4&14].

Currently, several plant pharmaceuticals have been used as natural anti-fungal formulations instead of synthetic anti-fungi which are used as skin ointment due to their toxicity on liver and pancreases when used at high concentrations [10]So,Urgent approaches are needed to fight against extensively drug-resistant fungal infections. Prevention and control of the emergence and spread of antifungal resistance require global efforts contributing to the solution. New prophylactic and therapeutic strategies must be developed as the existing antifungals become ineffective. Plant essential oils (EOs) constitutes a group of phytochemicals with potential application in development of novel antifungal agents that could contribute to the reduction in drugs use and thus to the maintaining of drugs effectiveness. Additionally, several reports demonstrated that they present a synergistic effect in combination with drugs thus they could be employed in the development of safe drug associations for fighting multi-drug resistance [12 & 15], also threre are a new method and preservatives techniques, in capsules and dry tablets, have been innovated to facilitate using of these plants and maintain their antimicrobial activity [1 & 2] . The aim of the present study was the investigation of antifungal properties of plant essential oils (EOs extracted from Eugenia aromaticum and Thymus vulgaris -M-ET) against Candida albicans clinical strains.

Materials and Method

Samples Collection and Isolation of C. albicans: A total of 16 clinical isolates were collected using sterile swabs from patients showed a clinical sings of

Candidiasis. A samples were collected from different sites, i.e. respiratory tract, wound and urinary tract infections, *Candida albicans* was included in the present study. Samples were collected at admitted at the Al-Hussein teaching Hospital and inoculated directly in a test tubes containing phospate buffer saline (PBS). All samples were kept at refrigerator (4°C) until the time of inoculation and identification**.**

Direct Examination and culture: Each sample was directly examined microscopically and stained using Gram staining method to identify the Gram-positive yeast [6,10]. For direct examination and identification of yeast cells and pseudomycillium, light microscope was used at (40X, 100X). Microbial strains were identified using the automatic system Vitek II.

Plant EOs: Essential oils used in this study were extracted in laboratories Al Muthanna university- faculty of science, department of Biology, from the mixture of *Thymus vulgaris* and *Eugenia aromaticum*. These were separately grounded and powdered in domestic blender and hydro distilled in a Clevenger's apparatus to obtained essential oils. Dilution was made after a known volume of each oil was diluted by adding fresh solvent (DMSO) and stored at 4°C till used.

Assessment of the influence of plant EOs on microbial isolates growth: Binary serial microdilution method performed in 96-well microtiter plates was used to determine the minimum inhibitory concentration (MIC) for each of the plant EO against the above mentioned fungal strains. Briefly, microbial suspensions prepared from 24 hours microbial cultures were adjusted to a density of 0.5 Mc Farland, corresponding to 1.5 x 108 CFU/ml and added in wells containing a range of plant EOs prepared by binary serial dilution using DMSO. After inoculation, microtiter plates were incubated for 24 h at 37°C. Wells containing broth inoculated with microbial strains and wells with uninoculated broth were used as positive growth controls and as negative controls, respectively. Solvent control tests were also performed to determine the effect of DMSO on microbial growth. The experiments were performed in duplicate. MICs were determined as the lowest concentration inhibiting microbial growth, indicated by a visible decrease in the growth medium turbidity.

Results and Discussion

We determined the effects of plant essential oils extracted from *Eugenia aromaticum* and *Thymus vulgaris -M-ET)*, at various concentrations, on growth of fungal strains isolates using turbidity measurements. Our study revealed that the investigated EOs displayed good antifungal growth effects. The results of antifungal tests are presented in the Table 1. We found that the mixture of M-ET was very efficient. The *C. albicans* strains were susceptible to the tested EOs, with MIC values ranging from 0.7 - 5.56 mg/ml.

Table 1. Plant EOs MIC values (mg/ml).

Plant EOs Microbial strains	M-ET mixture min–max
C.albicans (n=16)	0.7 - 5.56

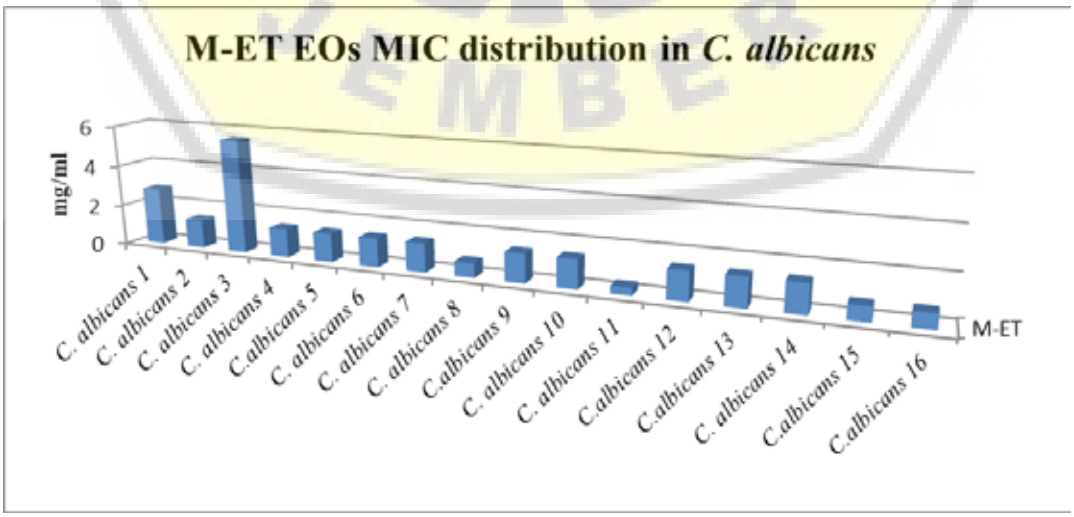

Figure (1): Minimum inhibitory concentrations for M-ET Eos

Antimicrobial resistance is a global health problem. The emergence and spread of pathogens resistant to current drugs require the development of new strategies[1&2]. Since ancient times, plant EOs are known to possess antimicrobial proprieties, however in order to develop adequate alternatives to the existing antimicrobials, we need first to better understand the mechanisms of the antifungal activity. In this study, we assessed the growth inhibitory activity of mixture *E. aromaticum* and *T. vulgaris* (M-ET) against fungal clinical isolates (*C. albicans*). Entire plant extracts and many of their individual components were demonstrated to possess antimicrobial activity against pathogens *in vitro*. In our study, we found that the tested plant EOs were able to inhibit the fungal growth with different intensities. The clinical isolates exhibited high variations in plant EOs susceptibility that could be explained by the various drug resistance patterns. The M-ET mixture demonstrated the strongest antifungal activity against all clinical isolates that probably correlated with the highest percentage of phenolic compounds, these results are in agreement with previous studies [3, 5 & 8]. According to Marchese (2017) p-cymene has enhanced the activity of other antimicrobial substances through synergism, antagonism and additive effects [11].

The antimicrobial activity of the tested plant EOs could be attributed to high amounts of phenolic compounds: eugenol about 75-85% of *E. aromaticum* EO (12), thymol, 57.7% and p-cymene 24.79% of *T. vulgaris* EO[3&17], The major antimicrobial phenolic components are, principally, acting as envelope permeabilizers[5].

Conclusions

With the increasing emergence of antifungal drug resistance, phytochemicals could constitute an alternative therapeutic strategy for fighting infectious diseases. Oily aromatic liquids extracted from plants represent a reservoir of bioactive compounds in nature. In this context, we analyzed the influence of: The mixture of *E. aromaticum* and *T. vulgaris* (M-ET) on drug resistant fungi. The overall results indicated that selected plant EOs displayed a good antifungal activity, that demonstrating their potential as bioactive alternative to conventional synthetic antifungal for controlling drug resistant fungi. However, for drug development additional tests are needed to determine their toxicity and pharmacokinetic and pharmacodynamic properties.

The Prevalence of Tension Type Headache among Students of Baghdad College of Medicine in 2018

Aqeel Kareem Hatem[1], Zuhair A. Al-Johar[2], Rand Abdul Jabbar Idrees[3], Mariam Ahmed Khalaf[3], Wasan Ahmed Shawket[3]

[1]Consultant Neurologist, Lecturer of Neurology, Department of Medicine, College of Medicine, University of Baghdad, Baghdad, Iraq, [2]Specialist of Neurology, Lecturer of Neurology, Department of Medicine, College of Medicine, University of Baghdad, Iraq, [3]Students at College of Medicine/University of Baghdad/Iraq

Abstract

Objectives: The main goal of this study was to estimate the prevalence of Tension-type headache "TTH" among students of College of Medicine\University of Baghdad "CM\UB"; to compare its prevalence between males and females, and to decide on its relationship with years of study in college; to estimate the relative proportion of episodic to chronic subtypes of TTH; and to identify aggravating\relieving factors of TTH.

Method: A cross-sectional survey study was conducted from the 28th of July 2018 to the 14th of October 2018 on 150 students of CM\UB. The data were collected by using self-administered questionnaire which included demographic data and specific questions on headache based on international Headache Society criteria (ICHD-III) for diagnosis of TTH and other headache types.

Results: Of 150 participant, 86 (57.3%) had TTH: in 78 (52%) it was episodic while in only 8 (5.3%) it was chronic. Neither age nor year of study had a significant relationship with TTH, but there was a significant difference between genders with higher prevalence in females (65.3%) as compared to males (49.3%). Stress, sound and lack of sleep were the most common triggering factors, while rest and sleep are the most effective relieving factors.

Conclusion: TTH is common among students of CM\UB, being more in females, and mainly episodic. Its prevalence was comparable with results from medical schools in nearby countries.

Keywords: *Headache, tension type headache, medical students, undergraduate, Baghdad.*

Introduction

Tension Type Headache "TTH" is the most common primary headache disorder in all age groups across the globe[1]. Several epidemiological studies have shown a high prevalence of headache among medical students. The prevalence rates of TTH have been reported in the range of (5.6-40.8%) in different countries[2,3].

TTH leads to considerable disability with up to 60% of individuals reporting decreased work effectiveness, increased absenteeism and reduced social engagement[4]. TTH often begins during the teenage years, affecting three women to every two men[5]. It is frequent among medical students and shows significant impact on their personal and social lives and the students often claim that their symptoms had worsened since admission to the university[6]. Some studies showed that particular years of study in medical schools are associated more with TTH[7], but this was not consistent among studies[8]. The relationship of gender with TTH in medical students was also variable across studies, some showed it to be more in females[9], but some studies didn't show that or even showed the opposite[7,10].

The term "Tension Type Headache" has been chosen by the International Classification Headache Diagnosis I (ICHD I)[11]. International headache society divides TTH into episodic and chronic types based on the frequency of the attacks. Episodic TTH occurring on

fewer than 15 days per month, is reported by more than 70% of some populations. It usually lasts a few hours, but can persist for several days. Chronic TTH, occurring on more than 15 days per month, affects 1-3% of adults. It can be unremitting and is much more disabling than episodic TTH[12].

There are also conflicting reports on aggravating\ alleviating factors of TTH, some affirming the role of stressors[13-15], others negating it[8]. As the cause of TTH is still unknown[16], epidemiological studies on specific populations are required to assist clinicians and researchers in finding the origin of pain and the factors influencing the frequency of headache[7].

Objectives: To achieve the following aims among students of College of Medicine\University of Baghdad "CM\UB":

- Estimate life time prevalence of TTH
- Determine the association of TTH with gender, age and grade.
- Estimate the proportion of chronic and episodic types of TTH.
- Identify aggravating\relieving factors of TTH.

Subjects and Method

A cross sectional study was conducted among medical students of CM\UB from 28th July 2018 to 14th October 2018. The study was conducted in accordance with the Declaration of Helsinki, after approval from Medical Education unit of CM\UB. This study enrolled 150 students who were selected randomly for the purpose of the study. The targeted Medical students were from 2nd, 3rd & 4th grade (year of study), for the age groups 18-23 years from either gender. Data were collected online using self-administered questionnaire. The questionnaire was designed by the researchers according to the international headache standards (IHS), and contained individual's demographic information such as age, gender, grade and questions to identify the type of headache. All subjects were classified by using 3rd edition of the International Classification of Headache Disorders "ICHD-3"[17] to make the differential diagnosis between TTH, migraine and cluster headache according to the responses provided by the research subjects. And then we sub-classified TTH to episodic and chronic according to the frequency of the attacks.

Statistical Analysis: All data were statistically analyzed by using the Statistical Package for the Social Sciences (SPSS) software (version 25) at level of significance ($P \leq 0.05$) Descriptive statistics were presented in frequencies, percentages, standard deviations, and 95% confidence intervals.

The differences among groups were analyzed by using logistic regression model for showing the influence of the factors of age, gender, and grade on the type of the headache; and by using z-test (for proportion) for differences in aggravating/alleviating factors of headache.

Finding: There were 75 males and 75 females participating in this study which represent 50% and 50% respectively. The age of participants ranged between 18 and 23 years with a mean equaling 20.59 years ± standard deviation of 1.181 years (95% CI: 18.3-22.9). The mean age for males was 20.67 years +/- 1.277 standard deviation (95% CI: 18.2-23.2), while for females it was 20.51 +/- 1.073 standard deviation (95% CI: 18.4- 22.6), both males and females age ranged from 18 to 23. The number of participants at the second stage were 58 (32 F, 26 M), at the third stage 47 (25 F, 22 M), and at the fourth stage 45 (24 F, 21 M).

The study showed that out of 150 students, 114 (76%) had headache, this was distributed as: 57.3% (n=86) had TTH, 16.7% (n=25) had migraine, 2% (n=3) had cluster headache and 24% (n=36) had no headache. The distribution of those per gender and age were calculated and depicted in Fig. (1,2) respectively.

The descriptive statistics showed that the age of 86 students with TTH was distributed between 18 and 23 years with a mean of 20.52 years and standard deviation of ± 1.193 (95%CI [18.18-22.86]). Those were distributed as follows: 3(3.6%); 13 (15.7%); 25 (30.1%); 28 (33.7%); 8 (9.6%); 6 (7.2%), per years of age (18 to 23) respectively; with 35 (40.7%); 29 (33.7%); 22 (25.6%) in 2nd, 3rd, and 4th grade respectively.

Of 150 participant, 86 (57.3%) had TTH: 78 (52%) had episodic TTH and only 8 (5.3%) had chronic TTH. of all 75 males: 37 (49.3%) had TTH, in 35 (46.7%) it was episodic and just in 2 (2.6%) it was chronic. of all 75 females: 49 (65.3%) had TTH, in 43 (57.3%) it was episodic and just in 6 (8%) it was chronic. The percentages of episodic and chronic TTH per age were calculated and are depicted in Fig. (3).

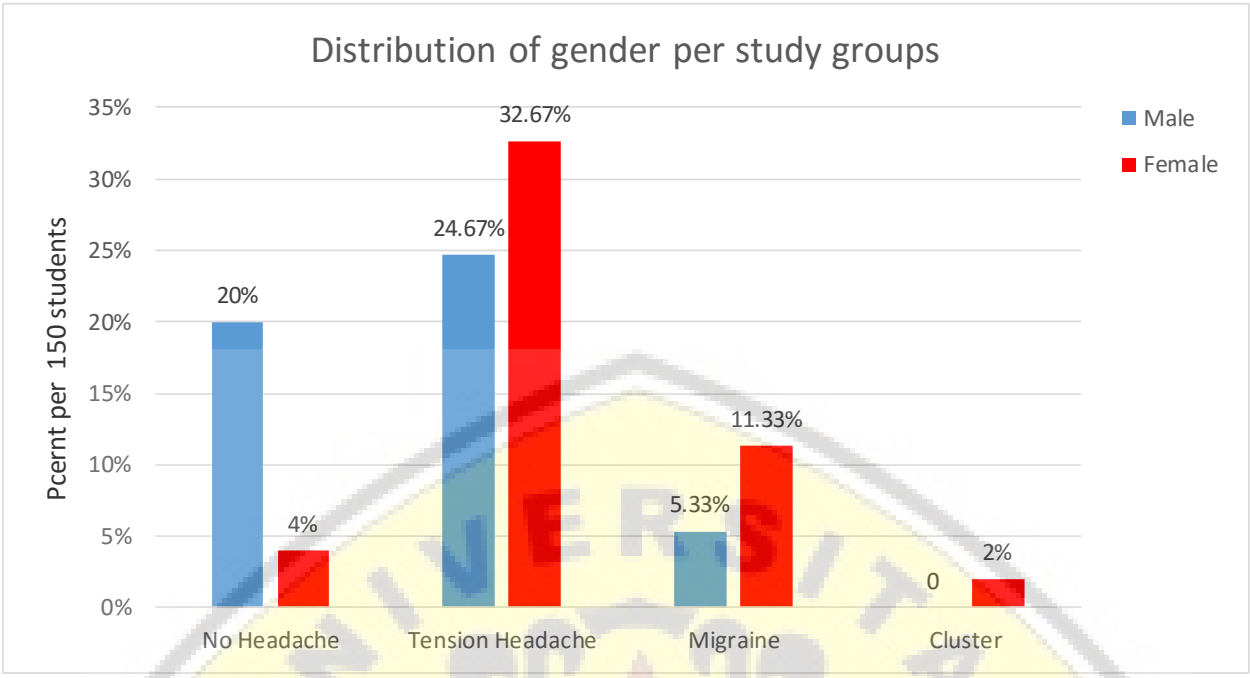

Figure 1: Bar chart showing the distribution of gender per study groups in a sample 150 students of Baghdad medical college.

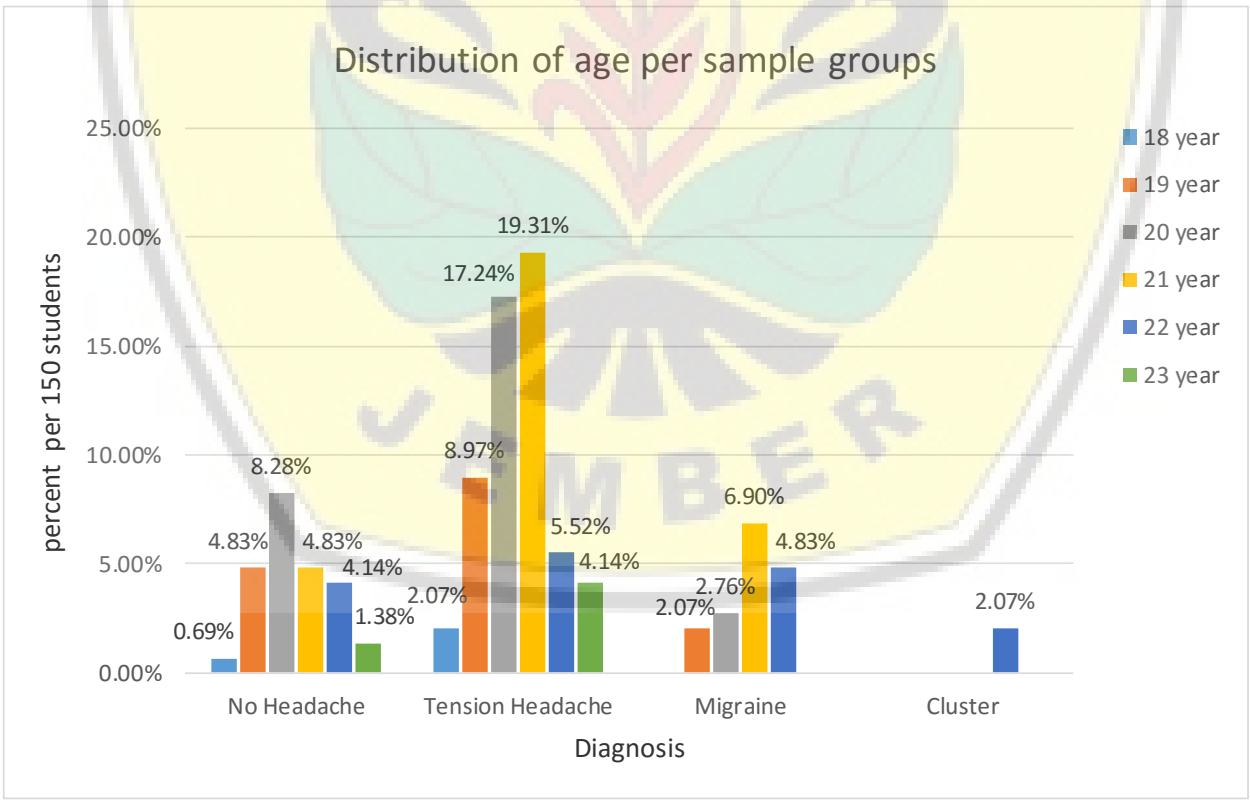

Figure 2: Bar chart showing the distribution of age per study groups in a sample of 150 students of Baghdad medical college.

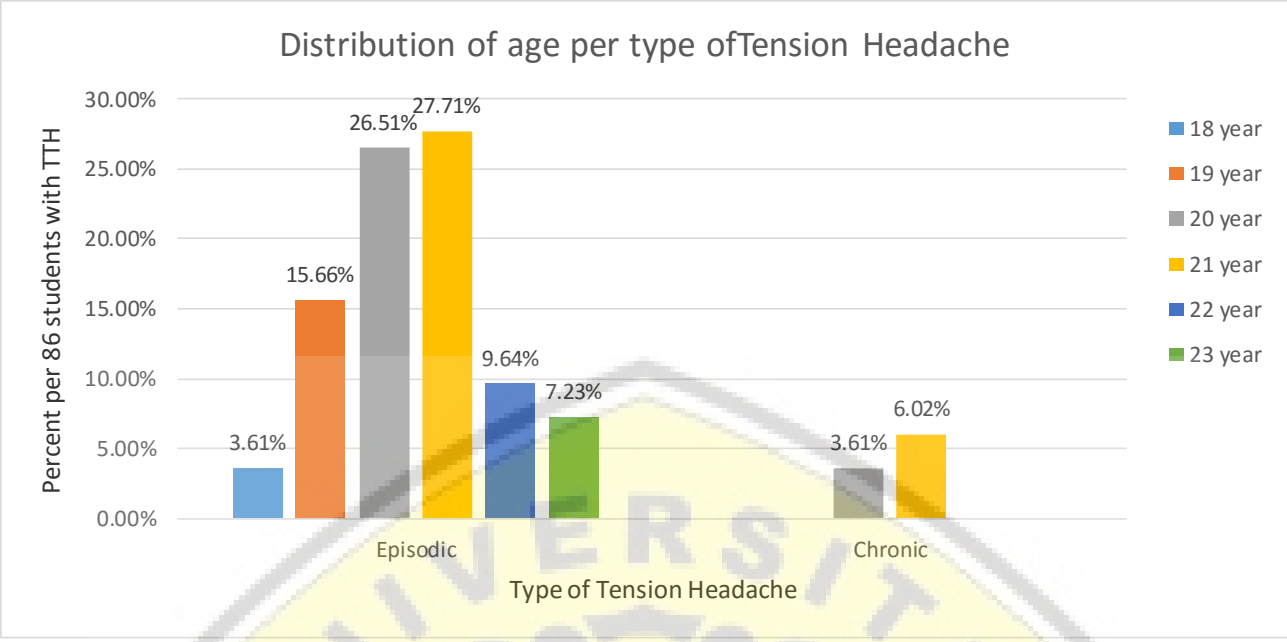

Figure 3: Bar chart showing percentage of types of TTH in relation to age in a sample of 86 students of Baghdad medical college with TTH.

The results also showed that out of 114 participants with headache: 8.8% (n=10) occurred daily, 28.1% (n= 32) occurred once a week, 35.1% (n=40) occurred more than once a week and 28.1% (n=32) occurred once a month. Regarding TTH: 8.1% occurred daily, 29.1% occurred once a week, 32.6% occurred more than once a week, and 30.2% occurred once a month.

Logistic regression model had been used to show the influence of age, gender and grade on the type of the headache, and to show the influence of these factors on TTH especially (Tab. 1).

Table 1: p-values of influence of age, gender and grade on the type of headache and influence on TTH

Factors	Studied Sample		Tension Headache	
	P-value	Influence	P-value	Influence
Gender	0.030*	S	0.045*	S
Age	0.121	N.S	0.222	N.S
Grade	0.272	N.S	0.379	N.S

Headache's type is a dependent variable
*statistically significant, S statistically significant, N.S not significant.

Frequencies and significance of aggravating factors of headache in tension and non-tension groups were calculated (Tab. 2). Similarly these were calculated for alleviating factors in those groups (Tab. 3).

Table 2: Frequency table of the factors that bring on\ aggravate headache

Factors	No Tension Headache (28)		Tension Headache (86)		z-test statistic	P-value
	N	%	N	%		
Stress	8	29%	80	93.0%	7.0597	<0.00001

Medication	20	71.4%	50	58.1%	1.2546	0.2113

Discussion

This is the first study reporting the life time prevalence of headache and particularly TTH in CM/ UB. The prevalence of headache in this study was 76% which is higher than what's found in a study in Iran (58.7%)[7] and much lower than a study conducted in Oman (98.3%)[10], both of which were conducted on medical university students.

In the present study TTH was found to be common in medical students of CM\UB with the overall prevalence of 57.3%, which is in line with a number of studies on medical students that were conducted in Iran (44.2%)[7], Turkey (50.7%)[18] and Saudi Arabia (58%)[8], as well as in Zagreb (57.69%)[9], yet it is much higher than a study conducted in Iraq[19] on the general population (21%), and also higher than the prevalence of TTH reported in the Middle East area (11-39%) [10, 20- 22], which might signal a possible correlation between TTH and university study of medicine in Iraq.

In our study, TTH was more frequent than migraine (16.7%) and cluster (2%), in agreement with studies done in universities in nearby locations: Isfahan[7] (44.2% TTH versus 14.2% migraine); Jordan[23] (36.9% TTH versus 7.7% migraine); Zagreb[9] (57.69% versus 8.86%); while in Oman[10] both were equal (12.2%). However the last study[10] contained a higher percentage of females in its sample (62.5%).

The generally believed higher prevalence rate of TTH among women, reflected by several studies, was observed in our sample with a prevalence of (65.3%) in females versus (49.3%) in males. This is in agreement with the findings of the study carried out in University of Zagreb Medical School (25.9% male, 70.1% female)[9]. However, some studies found no significant difference between male and female students like studies that are conducted in Isfahan[7] (49.2% in males vs. 39.2% in females) and the one conducted in Oman (13.9% in males vs.11.1% in females)[10].

In our study, grade showed no significant relationship with TTH, which comes in conflict with some studies like the study conducted in Isfahan which reported significant relationship with 3rd year study[7].

Several studies have reported the effect of age on different types of headach[24]. Considering the limited age range in this study; we did not observe any effect of age among sufferers from TTH, which agrees with the study in Isfahan[7].

Regarding the types of TTH, our study showed that the prevalence of episodic TTH is 52% (46.7% of males; 57.3% of females) and prevalence of chronic TTH is 5.3% (2.6% of males; 8% of females), which comes in agreement with a global report[12].

Among the factors affecting the intensification of

tension headache, stress had the highest effect (93%), which conflicts with results of a study in Taibah University in Saudi Arabia on 3rd year female medical students, which reports no relationship with stress[8]. However our results agrees with many prior studies on TTH in general[13-15]. Sound (phonophobia) intensified TTH in (54.7%) in our study and it was significantly different even from migraine group which also had phonophobia, this agrees with results of a prior study on the relationship of phonophobia with TTH[25]. Lack of sleep occurred in (50%) of students with TTH in our sample, which agree with prior studies on TTH in general[14,15], however lack of sleep was significantly found to be more with migraine than TTH, which comes in agreement with prior studies[15]. Rest and sleep are the factors found in our study to be with the highest effect on relieving TTH by (72.1%) and (70.9%) respectively, coming in agreement with prior studies[13,14] which agrees with what's generally mentioned about TTH in various textbooks[26], though this conflicted with another study[15].

Conclusion

- TTH is common among medical students in CM\UB, being more in females, and mostly episodic.
- There is no significant association between TTH and age or year of study in CM\UB.
- Stress, sound and lack of sleep are the most common triggering factors, while rest and sleep are the most effective relieving factors.

Evaluation of DNA Damage and Antioxidants Defense Systems in Type 2 Diabetes Mellitus Patients

Ayad M.J. Almamoori[1], Wasan K. Alwan[2], Maher M. Khadairi[3], Mohammed J. Al-Jassani[4], Saadi Mohammad Salh[5], Nahidh Mohammad Jabur Almamori[5]

[1]Department of Biology, College of Science, University of Babylon, Iraq, [2]Al-Furat General Hospital, Baghdad, Iraq, [3]Babel Health Directorate, Ministry of Health, Iraq, [4]Department of Microbiology, College of Science, Al-Karkh University of Science, Iraq, [5]Department of Anesthesia, Alexandria Hospital, BabelHealth Authority, Iraq

Abstract

The presents study was conducted to evaluate the DNA damage markers, antioxidants makers and lipid peroxidation in type 2 diabetes mellitus patients.

About 5ml of venous blood was collected from10 healthy persons and 30 patients,fasting for 10 hours. Comet assay used to measure DNA damage andantioxidants were assessed biochemically. Lipid peroxidation was estimated by the Thiobarbituric acid assay.

The results of presents study showed that the DNA damage markers such as comet length, tail length, DNA% in tail and tail moments were increased significantly at $p<0.05$ in diabetic patients as compared with healthy control group. Also, all biochemical markers such as SOD, CAT, GPx, GSH and MDA were significantly elevated with diabetic patients as compared with healthy control

Keywords: *DNA damage, Comet assay, Antioxidants, Diabetic mellitus.*

Introduction

World Health Organization demonstrated that more than 170 million people hve diabetes worldwide and in 2030, this number might rise to 370 million [(1)]. Complications of micro vascular and macrovascular of diabetes mellitus are the leading cause of mortality and morbidity [(2)].

Many biological pathways are triggered in hyperglycaemia state like glucose autoxidation, polyol pathway, prostanoid synthesis and protein glycation,leading to increased free radicals production where Oxidative stress is a common pathogenic factor in diabetes mellitus and its complications [(3,4)].

In human, there are antioxidant enzymes like superoxide dismutase (SOD), Catalase (CAT), Glutathione (GSH) and its enzymes such as Glutathione reductase (GR), Glutathione peroxidase (GPx) & glutathiones-transferase, which scavenges the free radicals actionin order to protect the body[(5)]. Some studies have estimated the status of oxidative stress in diabetics and reported oxidative damage in Diabetic mellitus patients [(5,6)].

Polyunsaturated fatty acids are readily oxidized by reactive oxygen species (ROS) to produce fatty acid radicals that generate new free radicals by reacting with adjacent lipid molecules. Breakdown of lipid peroxidation products form many reactive aldehydes like MDA which is highly reactive with protein and DNA molecules lead to form adduct with these macromolecule[(7)].

Hyperglycemia generates ROS then oxidative stress in many tissues that generatediabetic complications like protein, lipid, and DNA modifications could lead to teratogenic or carcinogenic consequences [8-10].

There is an increasing concerns of the DNA damage effect in chronic diseases. Comet assay is a sensitive, simple, economic and rapid technique to detect DNA damage and repair, radiation pollution, genetic toxicology and aging[11-14].

Materials and Method

Collection of blood samples: About 5ml of venous blood was collected from 10 healthy persons and 30 patientsfasting for 10 hours.

DNA damage measurement: About 100µl of venous blood was put in a 2ml microfuge tube containing 1.5ml of phosphate buffer solution. Then 40µl of proteinase K were added and Centrifuged at 10000xg for 15min at4°C then2-5µl of cell suspension transferred to a clean 1.5ml tube and mixed on Comet slide with 40µl of low melting agarose. Lysis solution was prepared that consist of 2.5M NaCl, 100mM EDTA, 10mM Tris-base and 8g NaOH, all dissolved and volume completed to 700ml by deionized water.About 110ml was added of 1% tritonX and 55ml of 10% dimethyl Sulphoxide (DMSO), after that, the volume competed to 100ml by deionized water and stored at 4ºC or on ice for at least 20min before use.About 7.5µl of the solution was combined with 75µl of low melting agarose and immediately the mix was spread on the clear part of a comet slide, then warmed on a heating plate at 42-50ºC before application.Slides were stored in lysis solution at 4ºC for 60 minutes, then the lysis solution was replace by alkaline solution containing 6g NaOH and 500µl of 0.5% Na_2EDTA for 60minutes at room temperature in dark. The slidesremoved from alkaline solution and washed by immersing in 1X TBE buffer for 5minutes. They were transferredto horizontal electrophoresis apparatus and placed on the gel tray and 1X TBE buffer was poured to cover the slides. The apparatus was run for 60 min. at 70V, then gently tappedto get excess TBE off and some drops of 70% ethanol were added on slides to remove the water. Sildes were stained by ethidium bromide and left for 24hour before checking by fluorescence microscope [15].

Antioxidants Measurements: SOD activity was determined by autoxidation of Pyrogallol according to [16]. While CATactivity was measured according to procedure of [17,18]. GSH activity was measured according to[19], the acid soluble sulfhydryl groups form a yellow colored complex with dithionitrobenzene (DTNB). The activity of GPx was investigated according to procedure of [20].

Lipid Peroxidation: Lipid peroxidation estimated using Thiobarbituric acid assay for Malondialdehyde (MDA) concentration according to[21,22].

Statistical Analysis: Data of present study was analyzed using SPSS(V.20) to find means, standard deviation and least significant differences by ANOVA. Values where $p<0.05$ is represented significant.

Results

DNA damage Markers: According to figure (1), the DNA damage markers were showed significant differences in control and patient according to statistical analysis at ($p<0.05$). The Comet length record highest Mean±SD in patients was reached to(107.6±5.6) µm as compared with control (22±2.1µm) figure (2). The tail length was recordedin patients (6.64±1.9) µm While in control (1.88±0.23µm) figure (3). While the DNA% in tail in control of serum was (0.77±0.02%), while in diabetic patients reached to (3.27±0.54%) figure (4). Whereas thetail moments in patients (1.38±0.34µm)and (0.55±0.02µm) in controlfigure (5).

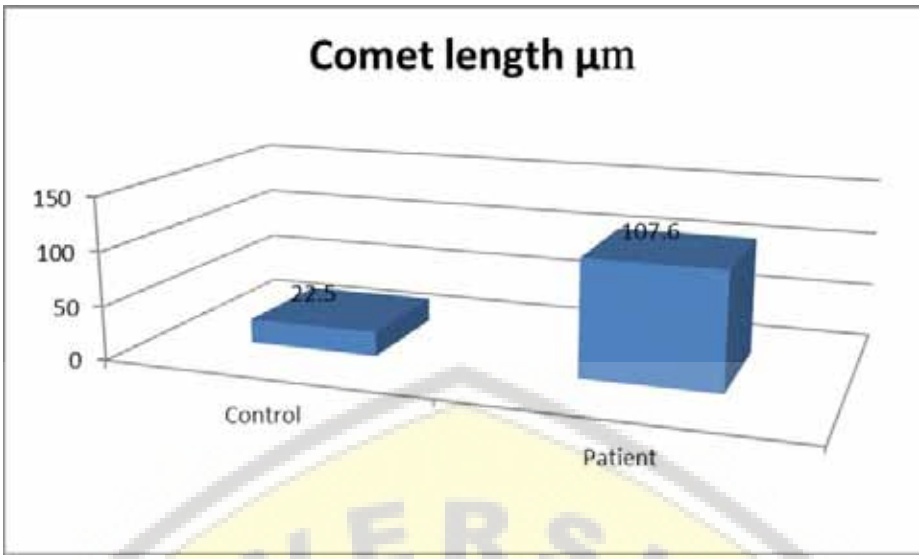

Figure 2: Comet length in control and diabetic patients

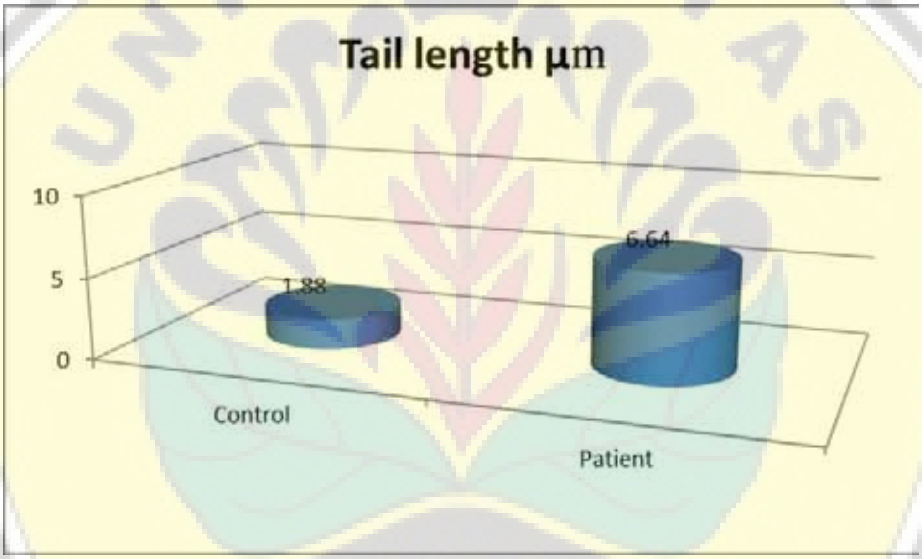

Figure 3: Tail length in control and diabetic patients

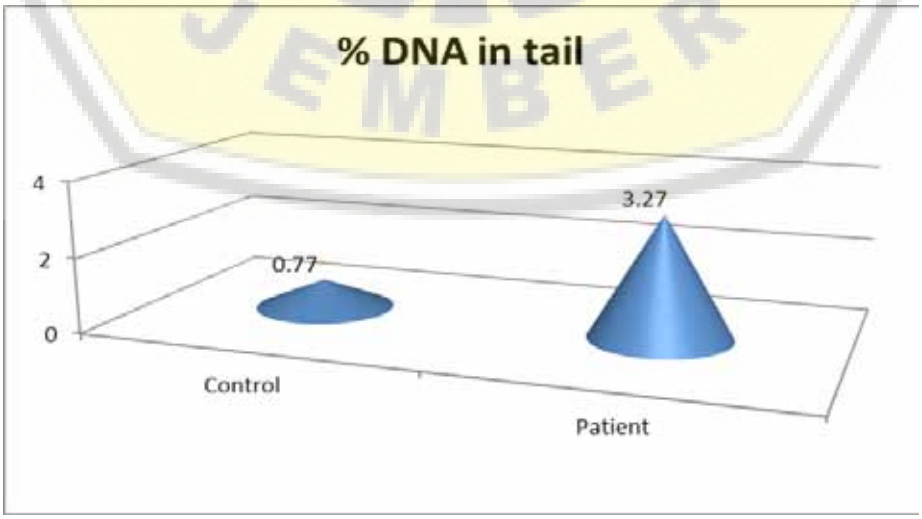

Figure 4: DNA % in tail in control and diabetic patients

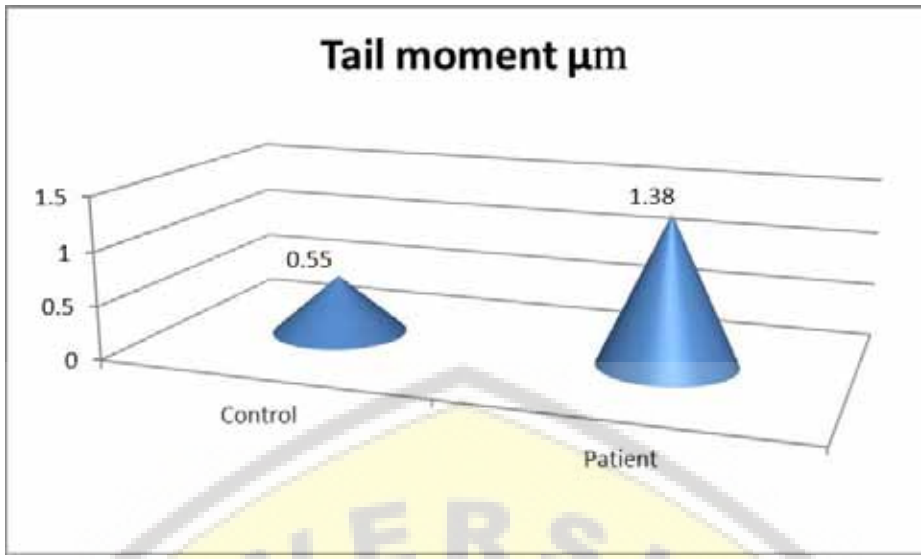

Figure 5: Tail moment in control and diabetic patients

Biochemical Markers: All biochemical markers was showed significant differences between control and diabetic patients, the SOD activity in serum of control were (22±2.4U/mg), in patient was reached to (201±21.9U/mg) while the activity of CAT in control of serum was (15±2.8U/mg) and in diabetic mellitus patients which elevated to reach (180±22.4U/mg).

The GSH activity was showed significantly differences between control and diabetic patient, it's activity in control of serum was (45±3.5µmol/ml), while activity in the patientsrise to (280±34.5µmol/ml).

Significant differences between control and patients in GPx activity, it's activity in serum control was (33±3.5µmol/ml) and the activity were elevated to (177±34.5µmol/ml) in diabetic patients. The concentration of MDA was significantly difference between control and patients in serum, it's activity in control of serum was recorded (15±1.07µmol/ml), its activity was increased in diabetic patients to reach (190±6.7µmol/ml)(figure 6).

Discussion

The association of diabetes mellitus with oxidative stress, leading to oxidation of protein, lipid peroxidation. Also effects on antioxidants status in initial effects of most toxic molecule that inter the body of human and organism can cause increasing the activities of all antioxidants defense, While in the final stage of its effects, the antioxidants activities will be decreasing due to oxidative stress that occur by free radicals and DNA damage [23]. The oxidized base 8-OHdG in blood or urine, can also be used as a DNA damage marker [24].

Comet assay used for measuring of DNA damage, as less susceptible method to artifacts than measuring 8-OHdG,more sensitive that detect very low levels of DNA damage [25].

High level of ROS in diabetes cause DNA strand breaks and base modifications (oxidation of guanine to 8-OHdG)[26,27]. Other studies reported that there is no relation between diabetes and increased levels of DNA damage [28]. This is possibly due to the difference in glycemic control, diabetes duration or the cell type used in the assay [27].

The SOD and CAT were increased significantly in diabetic mellitus patients' serum due to oxidative stress was generated by free radicals that cause induction lipid peroxidation, imbalances in antioxidants defense and increased ROS formation [29].

GSH regulates the intracellular redox status and cofactor in many metabolic reactions [30]. A significant elevation observed of GSH in serum of diabetic mellitus patients as compared with control may be due to animbalance in the redox state that induce compensatory response because of excessive H_2O_2 production, oras a result of overproduction for cell protection against oxidative stress [31] and increased demands on GSH utilization [32].

The GPx is catalyzing the reduction of H_2O_2 to oxygen and water by using GSH as a substrate. The result of present study pointed the GPx activity also significantly increased in the serum of diabetic mellitus patients as compared with control due to the response of antioxidants systems and to reflect the adaptation to oxidative condition [33].

Lipid peroxidation play key role in generation of pathogenesis disease that occur by oxidative stress through imbalance in low production of antioxidant defense and high production of ROS that lead to increase in lipid peroxide level [34].

The results of present study showed that the concentration of MDA was significantly increased in serum of diabetic mellitus patients as compared with control because the oxidative stress that occur by free radicals that cause increase inlipid peroxidation [34].

Conclusion

The present study showed increased DNA damage through elevation in markers of DNA such as comet length, tail length, DNA% in tail and tail moments the leukocytes of diabetic patients. In addition, to significant increase in SOD, CAT, GSH, MDA and GPx activity

The Relationship of Some Elements of Physical Fitness in Women Aged (35-45) Years on the Fat Component and Some Body Measurements

Atheer Abbas Mustafa[1], Ahmed Abdulameer Ahmed[1], Jasim Saleh Jasim[2]

[1]Asst. Prof., [2]Lec., Dept. of Students Activities/University of Basra/Iraq

Abstract

The scientific progress is one of the main reasons that helped the development of human life, and this progress covered all areas of life, including the health of society through investigating the physical and functional variables that can affect an individual's daily life. From a scientific point of view, fitness contributes to the development of the individual through its direct impact on functional organs. The study aims to identify some elements of physical fitness in women and their relationship to the fatty component and some physical measurements to understand the positive and negative effects of this relationship in order to develop and improve the health aspect of the individual.

The problem of study is the increasing of weight and fat in the body which has negative effects on the general fitness in women and their feeling of poor health. The sample of the study includes women who are participating in some fitness centers in the province of Basra. They are (37) women and the ages (35 - 45) years. They are the sample that researchers focus on for the sake of their work. In order to achieve the aims of the study subject, the researchers have presented the results and analyzed them according to the set aims, they found that there was a statistically significant relationship between some elements of physical fitness and fat component on the one hand and physical measurements on the other hand in the sample of the study.

Keywords: *Community health, physical variables, fitness, fat component.*

Introduction

The scientific progress of the world is one of the main reasons for the development of human life through the scientific and programmed planning that contributes to the achievement of human goals. This progress has covered all fields of life including community health, by knowing the physical and functional variables that can effect an individual's daily life. The fitness contributes to the development of the individual from a scientific point of view through its direct impact on the functional organs. Different studies and researches have shown that there is a close relation between physical fitness and the general health of the individual.(1)

The significant of the study: The importance of the research is to identify some elements of physical fitness in women and their relationship to the fatty component and some physical measurements, to understand the positive and negative effects of this relationship in order to develop and improve the health aspect of the individual.

The aims of the study: The study aims to know the relationship between some elements of fitness and both the fat component and body measurements.

The procedure of study: The different curriculums which are used in the implementation of scientific research and procedures come according to the type of

University of Basra/Iraq

study. That is the curriculum means following logical steps in dealing with problems, phenomena and resolving the scientific issues to reach the discovery of truth .[2]

The researchers have used the descriptive method, which studies the phenomenon as it exists in reality and cares as an accurate. So, it is appropriate for the problem of study. One of the things that should be considered in the field of study is the selection of the sample that represents the real representation of the study community to achieve the aims of study. The researchers determined the sample intentionally, a sample of women participating in fitness centers in the province of Basra (37) women. They are the sample that researchers have to focus on for the sake of their study in which they want to generalize the results of their study. To solve their problem, researchers must provide the means, tools and devices for their study, appropriately to ensure the success of their study, because "The tools study are the means by which the researcher can solve his problem whatever those tools data, samples, devices"[3]

The researchers are used Arabic and foreign sources, two Japanese electronic clocks, an Italian-made medical scale, caliper to measure the thickness of skin folds (grease), measuring tape for measuring length, distances and a small wooden box mounted on one side of a ruler with a length of (30) cm used to measure the flexibility of the spine, the back muscles of the thighs and the Grib Dynamometer to measure the strength of the first muscles. One of the physical measurements that researchers measured was measuring the weight of all the individuals of the sample by using a precision balance designed for this purpose as well as measuring the length of the body which is measured to the nearest cm by using the measurement of height. From the previous two measurements, the researchers extracted BMI: It is extracted by dividing the weight (kg) by the square length (meters).

BMI = Weight (kg)/Length (m) * length (m)

One of the measurements made by the researchers was the measurement of the fatty component. The test operator holds the meter with his right hand and holds with his left hand the fold of skin from the area indicated for it. Then, he takes the measurement and record the score in the registration form. Thus, he takes the measurement of the rest of the skin areas specified for measurement taking into account that one side of the body which is measured as well as measuring one area three times and taking the average readings. The four position equation was used (arm, abdomen, thigh, and iliac bone)for (Jackson and Pollock) in calculating the percentage of fats:[4]

Fat percentage = 0,29288 (the total of the four areas)-0,0005 (the total of the four areas)2 + 0,15845 (age) - 5,76377: As for the physical test that researchers conducted, it is the wide jump test of stability. The aim of this test is to measure the explosive strength of the muscles of the legs. The tester stands on the front edge, bounces and feet parallel to the breadth of the pelvis from the position of the bend of the mid knees and the measurement that is made to the nearest centimeter (cm) left by the tester at the distance near the beginning of the measurement, each tester is given three attempts to record the best.[5] The second test is the sitting from lying in 20 seconds [6]. The aim of the test is to measure the strength marked by the speed of the abdominal muscles. The laboratory lies on the back of the mattress with its feet open by (30) centimeters. A female colleague installs the two legs once hearing the starting signal from the referee. The third test is the grip strength test. The goal of the test is to measure the strength of the first muscles (the flexor muscles of the fingers). The laboratory holds the dynamometer in its right hand and the arm is stretched without any bending in the elbow joint. Then, she is slightly away from the body. The first presses the dynamometer to try to bring out the maximum force possible and give each lab two attempts to score the best try. The front-resting test - bending the arms and extending them to 15th was applied to the research sample as well. The aim of the test is to measure the force marked by the speed of the two arms. The sample woman takes the front rest position on the ground so that the body is elongated in an upright position. At the signal, she begins by bending the arms and extending them upward for a full period and continues for 15 seconds for one try [7]. For the latter test, it is a test (flexibility) bending the trunk down from the standing position. The goal of the test is to measure the flexibility of the spine and posterior muscles. The material for the thighs . The sample woman stands on a small wooden box fixed on one of its sides with a ruler with a length of (30) cm divided by (15) cm from the surface of the box to the top and (15) cm from the surface of the box to the bottom. Then the laboratory begins by bending the trunk down with the arms extended downward, noting that the knees are not bent and steadfast in the last extent to which the laboratory reaches. The number that touches the fingers

of the hands is recorded so that from the surface of the box to the top the measurement is negative, and from the surface of the box to the bottom according to. The statistical program (spss) version 22 was used to process the results statistically.

Correlation coefficient values between the measurements of physical and physical search variables and between the physical measurements and the lipid component.

The correlation coefficient values between the physical measurements and the lipid component.

Table (1) Shows the correlation coefficient values between somatic measurements and the lipid component

The Difference	Calculated T	Correlation coefficient	Tests
Moral	8.93	0.386	Weight and lipid component
Random	1.98	0.071	Length and lipid component
Moral	7.78	0.265	BMI and lipid component

The results of Table (1) shows the emergence of a significant value between the weight and the fatty component, while the body mass index is also significantly correlated with the fatty component as this correlation is evidence of a direct relationship between these variables. This is consistent with what Osama asserted [8], "The very high and high fat levels are directly related to the increase in body weight." Further, what called for using the BMI as a measure to estimate obesity in individuals is that there is an acceptable correlation between the body mass index and measures of body fat percentage. [9] This is what is observed that any increase in weight or body mass index is accompanied by an increase in the percentage of fats, except for the increase in the muscle mass in the body that comes as a result of exercising physical activity on a continuous basis that "the process of losing or increasing weight due to those ideal weights found in the tables of weight and height may It is due to an increase in muscle mass and a decrease in the amount of fat from the required level. [10]

Correlation coefficient values between physical and physical measurements

Table (2) shows the correlation coefficient values between the parameters of physical measurements and physical characteristics

Tests	Correlation Coefficient	Calculated T	The Difference
Weight and bounce from stable	0.032	0.77	Random
Weight and the strength of the right hand grip	0.201	6.87	Moral
Weight and the strength of the left hand grip	0.187	5.23	Moral
Weight and forward leaning	0.027	0.69	Random
Weight and sitting lying down	0.021	0.59	Random
Weight and bend the body down	0.027	0.77	Random
Height and jump from stable	0.016	0.55	Random
Length and the strength of the right hand grip	0.015	0.40	Random
Length and the strength of the left hand grip	0.080	0.18	Random
Length and forward leaning	0.019	0.48	Random
Length and sitting lying down	0.030	0.69	Random

Tests	Correlation Coefficient	Calculated T	The Difference
Length and bend the body down	0.035	0.89	Random
BMI and jump from stable	0.011	0.28	Random
BMI and the strength of the right hand grip	0.185	4.75	Random
BMI and the strength of the left hand grip	0.158	3.88	Moral
BMI and leaning forward	0.017	0.31	Random
BMI and sitting from lying	0.008	0.13	Random
BMI and bending the body down	0.025	0.59	Random

Through Table (2), we notice the emergence of a significant value between weight and grip strength of the right hand, as well as between weight and the strength of the left hand grip. Further, a significant correlation appeared between the body mass index and the strength of the right hand grip and the strength of the left hand grip. [11] This moral correlation is evidence of a direct correlation between these variables. This corresponds to (Wind and Henry) study on a group of University of Michigan students with the aim of finding the relationship between the grip strength and both weight, height and age. The study has shown that there are correlations between the grip strength and weight. While it was noted that the relationship between the strength of the fist, height, and age was not distinctive and this was proven by (Verell & Sillse) that the strength of the first was affected by weight, size and size of the hand, height, and muscle pattern. [12]As for the emergence of the random value among the remaining variables, the researchers attribute the reason for this to the high weights that characterized the research sample due to the lack of physical activities necessary for the health of the body and give the necessary flexibility for ease of movement, and this confirms (Hazza) that the changes in the lifestyle of the society led to a decrease Average daily physical activity per person. " [13]

The importance of exercising and physical activity lies at a moderate intensity to increase the circulating hormone (Circulating Catechol amines) which have an effect on the movement of fats in adipose tissues that explain the fat loss that usually occurs through continuous training.[14]

Values of the correlation coefficient between the physical characteristics and the lipid component.

Table (3) Shows the correlation coefficient values between the physical characteristics and the fatty component

Tests	T calculated	Correlation Coefficient	The Difference
Jumping from stability and lipid component	0.043	0.94	Random
Right hand grip strength and lipid component	0.132	4.43	Moral
Left hand grip strength and lipid component	0.129	3.28	Moral
Leaning forward and lipid component	0.033	0.76	Random
Sitting from lying and lipid component	0.024	0.53	Random
Bending the body down and lipid component	0.044	0.86	Random

Through Table (3), we note the emergence of a significant value between the strength of the right hand grip and the fatty component, as well as between the power of the left hand grip and the lipid component. As for the relationship of the rest of the variables mentioned in the table, they are random with the variable of the lipid component, and the researchers attribute the reason for this to the increase in the percentage of the lipid

component in The body affects inversely with physical fitness. [15]The percentage of fat and muscle tissue has a close relationship with all other components of physical fitness. Each affects and is affected by the other." [16] Studies indicate that "the process of losing or increasing weight due to those ideal weights found in the tables of weight and height may be due to an increase in muscle mass and a decrease in the amount of fat from the required limit." [17] The studies also indicated that muscle strength develops with resistance training and is affected by the amount of non-lipid mass (Lean Body Mass) is positive and with increased lipid negatively. Anatomical Factors Affecting DXA Scan Measurement of Bone Mineral Density in Lumber Spine

Firas M. Ghazi[1], Zaineb Haythem Ali[2]

[1]Department of Human Anatomy/Collage of Medicine/University of Babylon, Iraq, [2]Ministry of Health, Iraq

Abstract

Background: Dual-energy X-ray absorptiometry scan is used to measure bone mineral density. Correct measurements greatly depend on accurate selection of targeted anatomical areas of bone. Various anatomical factors including anatomical knowledge can be a potential source of error; they can falsely increase or decrease measured bone mineral density. Technician ability to recognize these factors is critical for accurate scan analysis. The aim of study was to demonstrate the prevalence of different anatomical factors affecting Dual-energy X-ray absorptiometry scan results and to analyze how they affect final clinical decision.

Method: Using systematic random selection, Dual-energy X-ray absorptiometry records of lumbar spine for 50 patients were divided into two categories;the first was normal and affected by anatomical factor. The second category was divided into five groups (A1 – A5) containing a spectrum of anatomical factors that may influence bone mineral density measurements. Reports analyzed using measurements of bone mineral density, T/Z-scores from WHO based OPC. A1 and A4 were not analyzed further. A2, A3, and A5 reports were recalculated using anatomical landmarks.

Results: Data from current study showed that anatomical factors affecting bone mineral density were prevalent (72%). A1 included 14 cases (28%), A2 included 8 cases (16%), A3 included 8 cases (16%), A4 and A5 included 3 cases (6%) for each. Group A2 showed a significant increase in bone mineral density. T/Z-scores (mean±SD) after reselection of ROI, were 0.44±0.19. OPC changed in three cases from A2, 3, and 5 when T/Z-score was border-line.

Conclusion: Optimal DXA reports require well-trained technicians and expert clinicians who can recognize diverse anatomical factors influencing results. Effects of AF can be reduced by initiating or improving training programs of involved persons. Further studies are recommended to explore the extent to which each group of anatomical factors affects T/Z-scores.

Keywords: *DXA, anatomical factors, osteoporosis classification, bone mineral density.*

Introduction

Dual energy X-ray absorptiometry (DXA) is a standard tool in clinical assessment of osteoporosis. It can be used for diagnosis of, follow-up patients at risk of, and monitoring treatment response in patients with, osteoporosis[1]. It can measure fracture risk with high accuracy[2]. DXA scan is considered the first choice in clinical practice for its accuracy, efficiency, noninvasivenessand low radiation[3].

DXA scan measures the mineral content of bone (BMC). This value is converted into bone mineral density (BMD) by dividing BMC by surface area of measured bone[2].

World health organization (WHO) classified osteoporosis according to BMD results as follows:

Normal with BMD > (1 SD) below young adult mean, Osteopenia with BMD between (1 - 2.5 SD) below young adult mean and Osteoporosis with BMD ≤ (2.5 SD) below young adult mean[4]. These results are reported by DXA scan as T-score (equals to measured BMD – mean BMD in healthy young adults/SD of young population) and Z-score (equals to measured BMD–mean BMD in age-matched adults/SD of age-matched population). This WHO based osteoporosis classification (OPC) is used by most clinicians[5].

DXA machines can measure BMD in lumbar spine, hip and other regions. The usual AP view DXA scan of lumbar spine uses mean T-score of L1-L4 vertebrae to assess osteoporosis. Auto-analysis software of DXA machine selects region of interest (ROI) of lumbar spine which is the surface area of individual lumber vertebra from L1-4 with marking lines passing along intervertebral spaces. Manual adjustments of marking lines is often needed using local anatomical landmarks[6]. It measures BMC of individual vertebra, then BMD and T/Z-score of that vertebra is measured and mean is calculated[7]. In clinical practice, abnormal vertebrae can be excluded and two vertebrae are acceptably used to assess osteoporosis[1].

Factors affecting anatomy of spine can be a potential source of errors when measuring BMD. These factors includeincorrect positioning,anatomical variations,artifacts andabnormal progression of BMD from L1 to L4[1]. Another potential source of error is incorrect selection of ROI by DXA auto-analysis software which can contribute for up to 64.2% of inadequate reports unless technicians use anatomical knowledge to reselect ROI[6]. Incorrect positioning that leads to rotation of spine can decrease measured BMD by increasing surface area of vertebra[8]. Anatomical variations in spinal segmentation are common and can cause the device to mislabel vertebrae leading to erroneous report. Absent twelfth rib can lead to T12 being mislabeled as L1 with subsequent decrease in BMD. In addition, L2 is mislabeled as L1 in case of presence of L1 rib leading to an increase in measured BMD[9]. Artifacts on or even lateral to lumbar vertebra in AP-view (e.g:surgical clips)[10], osteophytes, fracture and/or end plate sclerosis[11], can significantly increase BMD value. There is progressive increase in BMD from L1 to L4, sudden changes from one to next vertebra can be due to vertebral fracture, or artifacts, in such cases mean BMD of L1-4 can show higher results[1].

This study wasaimed to investigatethe prevalence of anatomical factors affecting DXA scan results in local community, their effects on DXA reportand thereby on clinical decision.

Materials and Method

This study was retrospective analytical study that measured for BMD saved in DMS Stratos system located in outpatient-clinic in Hilla City Center, Iraq.

Records of 50 patients underwent assessment for lumbar spine BMD were selected from device database using systematic random selection for patients who visited the clinic from 1st, January 2016 to 30th, April 2016. Data collection considered T-score except for men below 50 years and premenopausal women whereZ-score was considered. Patients classified using WHO-based OPC into normal (T/Z-score above -1), osteopenic (T/Z-score between -1 and -2.5), and osteoporotic (T/Z-score below -2.5).

Cases were divided into two categories, those with no AF affecting their results (N), and those with scan errors caused by AF (A). The last category subdivided into five groups (A1-5). A1 included cases of incorrect positioning where DXA image showed bent or rotated spine and when parts of L1, L4 or pelvic brim are excluded from the field with inability to correctly identify vertebrae. A2 included cases in which ROI shifts up from usual L1-4 to T12-L3. A3 included images with incorrect boundary of ROI were marking lines crossed over bones rather than intervertebral spaces in addition to images in which ROI included artifacts lateral to vertebra. A4 included images with artifacts located on vertebra. A5 included images showing abnormal progression of BMD from L1-L4 not included in other categories.

Original measurements were reviewed such as mean BMD, T/Z-scores of L1-L4 were recorded. Stored images were classified into different groups of AF. For A2 & A3 reports, ROI was manually reselected using anatomical landmarks and new BMD, T/Z-scores were calculated. For A5, mean BMD, T/Z-scores were recalculated after excluding abnormal vertebra. No further analysis of group A1 and A4 was done. OPC compared with original results in group A2, A3 and A5.

Statistical Analysis: Prevalence of each group was calculated. Using paired *t*-test, we compared mean BMD and T/Z-score for groups (A2 and A3) before and after correction, and mean BMD, T/Z-score for group

(A5) before and after exclusion of abnormal vertebra. Sigmaplot for windows 12 was used to infer statistical data.

Results

Evaluation of reports revealed that 14 cases (28%) had no factors affecting measurements. However, 36 cases (72%) were affected by various types of AF (Table1). The distribution of AF according to designed groups was as follows: A1, incorrect positioning in form of bending, rotation or exclusion of part of T12 vertebra, included 14 cases (28%; Figure 1), A2 ROI shift-up to T12-L3 in 8 cases (16%) either because of software error (6 cases; 14%) or absent rib on T12 vertebra (2 cases; 4%) (Figure 2), A3 incorrect boundary of ROI markers (8 cases; 16%) of which two cases (4%) included artifacts lateral to vertebral bodies (Figure 3), A4 artifacts anterior to vertebral bodies and A5 abnormal progression of BMD values of L1-4 vertebra were seen in 3 cases (6%) for each (Table2).

Table 1: Distribution of DXA scans cases

Category	N*	A**	Total
Number	14	36	50
Percentage	28	72	100

*: Cases with no scan errors and no AF affecting measurements. **: Cases with scan errors resulting from AF.

Table 2: Prevalence of anatomical factors affecting DXA report

Group of AF	A1	A2	A3	A4	A5	Total
Number	14	8	8	3	3	36
Percentage	28	16	16	6	6	100

For A2, manual shift-down of ROI to usual L1-4 significantly increased BMD and T/Z-scores for all cases. Mean difference of T/Z-scores was 0.44±0.19 SD.OPC changed from osteoporotic to osteopenic range in two (4%) cases (Table 3).

Table 3: A2 factors before and after reselection of vertebra

Case No.	Factor involved	BMD values		T/Z scores	
		Before	After	Before	After
1	Shift-up	0.704	0.76▲	-3.1	-2.7▲
2	Shift-up	0.807	0.851▲	-2.3	-1.9▲
3	Shift-up	0.78	0.875▲	-2.5	-1.7▲*
4	absent rib	0.573	0.622▲	-4.2	-3.8▲

▲: Valueincreased. ▼: Valuedecreased.

OPC of 50 cases revealed that 6 (12%) had normal range T/Z-scores, 21 (42%) are osteopenic, and 23 (46%) are osteoporotic. Out of 19 cases from A2, A3, & A5 which were corrected, OPC changed in 3 (15%) cases. Two cases (10%) of A2 changed from osteoporotic to osteopenic and one case (5%) of A3 changed from normal to osteopenic. All three cases had border-line T/Z-scores

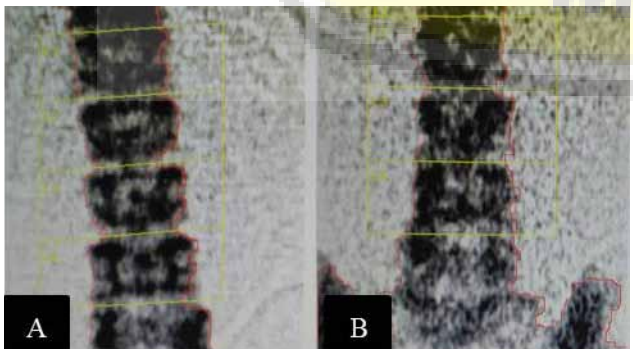

Figure 1: A1 factors showing bending (A) and incomplete L1 (B)

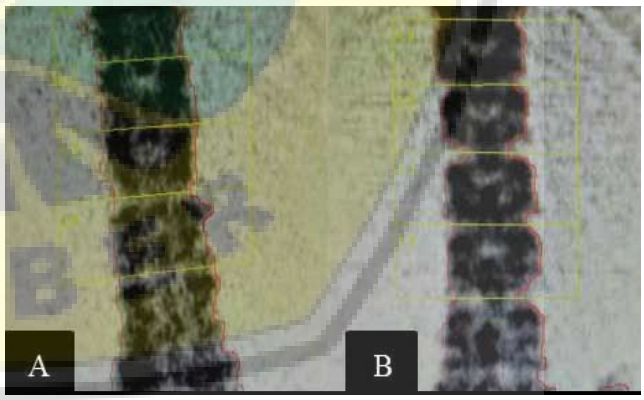

Figure 2: A2 factors showing shift up of markings (A) and absent rib on T12 (B)

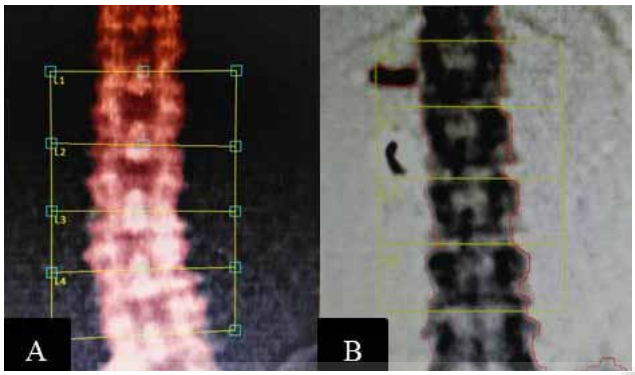

Figure 3: A3 factors showing incorrect boundaries (A) and lateral artifacts (B).

Discussion

Analysis of DXA reports of 50 cases showed high prevalence (72%) of AF affecting results. This may be due to small sample size. A larger study may provide lower results. Using auto-analysis of DXA machine without manual correction can result in more than 64% of inadequate reports. Health institutions should aim at highest level of accuracy in clinical diagnosis of osteoporosis through optimizing training programs of technicians.

A1 factors were most frequent AF encountered (14 cases; 28%). Most of cases were caused by bending or rotation of spine. Some researchers suggested that such reports should be considered invalid as straight position cannot be obtained[1]. Others recommend the use of scoliosis software to allow placement of non-rectangular ROI markers for more accurate definition of vertebra[12]. Vertebral rotation can falsely decrease BMD by 20%[8]. Clinicians should consider this fact when reading DXA reports with spinal rotation. Fewer cases are caused by absence of part of L1 as a result of bad positioning of patient. Technician should repeat DXA scan of this sub-type in order to optimize results. Researchers require that positioning should be checked by technologist before patient leaves the testing room and should also be double checked by clinicians interpreting the test[7].

A2 factors included 8 cases (16%) in which T12 was mislabeled as L1 vertebra. In two (4%) cases, the 12th rib was bilaterally absent which is the usual cause of such error[1]. Prevalence of bilateral absence of 12th rib ranges from 3.2%[13] to 6.6%[14]. In 6 (12%) cases, the 12th rib was normal. Auto-analysis software of DXA machine can cause shift-up from L1-4 to T12-L3 in 11.9% of cases[6]. Although this error is not directly related to AF, it is the anatomical knowledge of the technician that can affect the percentage of reports relying on auto-analysis only. After reselection of vertebra and subsequent correction, BMD and T/Z-scores increased in all 8 cases. L1 has higher BMD than T12[9]. Mean±SD difference in T/Z-score was 0.44±0.19 which is almost identical to a previous study[6]. This figure can be used to define border-line T/Z-scores in which OPC can change, but a larger study is required to set this value; this can help clinicians in making best clinical decisions.

A3 factors included 8 cases (16%). ROI markers crossed over vertebral bodies in five cases (10%). This percentage was lower than that from a previous study (17.9%) which relied on auto-analysis only[6]. Various artifacts were seen lateral to vertebral bodies in three cases (6%). In one of these cases there was a bone spike projecting from L1, in another case ROI included part of hip bone. Reselection of ROI in cases with incorrect boundaries decreased BMD in three cases which was expected because boundary lines dissecting vertebral bodies can increase the BMD[6], however, in our study the BMD increased in two cases this was because the boundary line dissected part of the twelfth vertebra which has lower BMD than L1[9]. All changes in BMD and T/Z-scores in all A3 cases were not significant; this can be due to that despite the surface area of an individual vertebra had changed, the total surface area did not change much.

In A4 factors, 3 cases (6%) contained image artifacts all were caused by presence of osteophytes. Cases of osteophytes overlapping with other groups were not considered. Artifacts anterior to vertebral bodies cannot be excluded from ROI. Osteophytes tend to increase BMD leading to underestimation of osteoporosis state. Metallic objects or fractured vertebra should be corrected by removing artifacts, or exclusion of vertebra from final results[1], but none was found in this study

In A5 factors, 3 cases (6%) were seen. Normally BMD increases progressively and is highest at L4[9]. This anatomical abnormality can be due to vertebral fractures, osteosclerosis, etc[1]. Plain X-rays of patients were not available, therefore; the cause was not explored. Recalculation of BMD and T/Z-score after exclusion of abnormal vertebra did not result in a significant change. Although affected vertebra should be excluded from final results[1], we suggest that in these cases exclusion of affected vertebra should only be applied if X-ray

showed evidence of anatomical defect like fractured vertebra, osteosclerosis, etc. and/or OPC is border line.

Out of 19 cases, OPC was changed in 3 (15%) cases only. Two cases from A2 changed from osteoporotic to osteopenic range. One case from A3 changed from normal to osteopenic range. In all three cases, T/Z-score was border line according to OPC. Although AF commonly affects DXA results, trying to correct these factors didn't result in significant change in final results. This agreed with a previous study[9], unless T/Z-scores are near to border line for OPC. Defining border-line T/Z-scores is of great practical importance.

Conclusions and Recommendations

AF affecting DXA reports are common; they can be a potential source of error and their effect on final results and clinical decision is much lower. Optimal DXA reports require well-trained techniciansand expert clinicians who can recognize diverse anatomical factors influencing results. Effects of AF can be reduced by initiating or improving training programs of involved persons. We recommend training operating personals on proper selection of ROI for best vertebral definition. Courses on how to accurately identify lumbar vertebra, exclude foreign bodies, properly align patient spines and mark abnormally low or high BMD are suggested.

Minor changes in reports with border-line T/Z-score may alter clinical decision and should be cautiously interpreted. Further studies exploring the extent to which each group of AF affects T/Z-scores are recommended to set a score range indicating border-line reports.

Survey of Isospora Belli Infection in Some Different Hosts: Birds and Mammals

Ikhlas Abbas Marhoon[1], Asifa Matrood Al-maeahi[1]

[1]Department of Biology, College of Education, University of Al-Qadisiyah, Iraq

Abstract

The current study aimed to revealing of isosporiasis in different species of birds and mammals which caused by *Isospora belli*, to achieve this target a 287 stool samples were collected from two groups which are : ten species belong to birds and five species belong to mammals distributed as follows: the birds included 30 samples of *passer domesticus*, 15 samples of *streptopeliadecaocto*, 25 samples of *Columba Livia*, 30 samples of *Columba domesticus*, 15 samples of *Anasplatyrhynchos*, 10 samples of *Anseranserdomesticus*, 10 samples of *Pycnonotusleucotis*, 30 samples of *Gallus gallusdomesticus*, 20 samples of *Coturnixcoturnix*, 10 samples of *Meleagrisgallopava*; the mammals included 20 samples for these species: *Canis lupus, Equusferuscaballus, Oryctolaguscuniculus*, 24 samples of *Feliscatus* and 8 samples of *Caviaporcellus.* All types of specieshave been collected from different provinces in middle of Iraq for the period from January 2017 until September 2018. The samples were kept in the refrigerator at 4°C until it tested in vitro by the preparation of the direct smear and then staining with Ziel- Neelsen stain (acid fast stain) to observe the oocysts of the parasite. DNA of positive fecal samples was extraction and amplification with 18S rRNA by using PCR technique. The results of stool test revealed that 127(44.25%) birds and mammals were infected with isosporiasisand there is no infection in fecal samples which isolated from guinea pig in this study. Also results showed a disparity in the infection rates among birds and mammals under study with a significant difference in the rates of infection between *Gallus gallusdomesticus* and *Pycnonotusleucotis* (73.3% and 10.0% respectively) at $P < 0.05$, the results of DNA electrophoresis confirmed examination results by staining with Ziel – Neelsen, the amplicons of DNA which belong to infected birds and mammals showed size at 550-630 bp. and the tested samples which belong to guinea pig didn't appear any band in agarose gel media.

Keywords: *Isospora belli, 18S rRNA, Cystoisospora belli, birds and mammals.*

Introduction

Isosporiasis is an parasitic intestinal disease that can infect many species of birds and mammals including human[1-3]. This disease caused by a parasite belong tococcidian called *Isospora belli* (recently known as *Cystoisospora belli*) which causes human coccidia disease[4] and it has a huge spread in the Mediterranean region, Africa and Latin America, also spreads in the Middle East and Far East regions and some infections had been recorded in the United States of America [5,6]. This parasite returns to the class: sporozoa, it attacks the small intestine of its hosts and its life cycle is very similar to intestinal cycle of Toxoplasma gondii. In the intestine where it is multiply within epithelial cells to formschizonts, later meroziotes invade a new epithelial cells (Asexual cycle)[7]. After a few asexual cycles, thesexual stagebegins byformation of gametocytes, when fertilization occurs the zygote formed which regrow later to immature oocysts which excreted forward out with stools, immature oocysts contain two sporocysts each one of them contain 4 sporozoites at this

Corresponding Author:

University of Al-Qadisiyah, Iraq
e-mail: ikhlas.abbas@qu.edu.iq

stage the oocystbecome mature and have ability to infect again when they are eaten or swallowed by a new host with food or water which containing it; when it reaches to small intestine; sporozoites release after the wall of oocyst and sporocyst are melted by host's stomach enzymes. Sporozoites invade the bowel cells and then they repeat their life cycle[8].

The immature oocysts which excreted with faeces have ability to stay infectivity until hard environmental conditions like high temperatures or severe light sun, it can maintain its ability to infect for several months and this parasite doesn't need the intermediate host to complete its life cycle, but the transition from infected host to another through contaminated water and food.[9,10]

Humans infection is usually occurring in people that suffering from HIV/AIDS, in particular HIV immunodeficiency syndrome [11], where the first infection was recorded in 1915 [7,9]. Symptoms are characterized by acute fatty blood-free diarrhea, abdominal pains with nausea and anorexia and symptoms may persist for weeks and this may cause lack absorption in epithelial layer of intestine, which results a decrease in total weight in general.[12]

Diarrhea is more severe in the case of children, infants and HIV patients [13]. One of the pathological changes occurring in the bowel wall are: dwarfism of villi, hyperplasia and swelling of intestinal grooves with large numbers of inflammatory cells, especially eosinophil, as well as plasma and lymphatic cells in submucous layer of the intestine [12].

Several studies have been done about isosporiasis, which including different hosts domestic and/or wild birds and mammals, from these studies: the study (14) in which they isolated this parasite from wild and pet bird feces and (15) were found isosporiasis infection in a bee-eating bird, in Australia *I. belli* was isolated from many species belonging to the family passerine form[3,16] and some study isolated this parasite from mammals like (1) they were found infection in tiger, the study (17) record 20.78% in stray dogs and 10.41% in stray cats. The incidence of this parasite is consider a zoonatic disease with HIV infected patients which recorded at 94.7% in Thailand [6,18] and recorded at 16.9% in Sao Paulo[19].

Because of the importance of this parasite at health aspects to humans and its domesticated animals and the fact that infected birds and mammals is an important source of continuous infection and spread it to many other hosts through contaminate of water and soil by oocyst, so this study aimed to detection extent of infection in different species of birds and mammals and determine the relationship between infection rate and the change of study's months.

Materials and Method

Collection of Samples: Atotal of 287stool samples were collected from different provinces in middle of Iraq which belong to different species (10 species belong to birds and 5 species belong to mammals) distributed as follows: the birds included 30 samples of passer domesticus, 15 samples of streptopeliadecaocto, 25 samples of Columba Livia, 30 samples of Columba domesticus, 15 samples of Anasplatyrhynchos, 10 samples of Anseranserdomesticus, 10 samples of Pycnonotusleucotis, 30 samples of Gallus gallusdomesticus, 20 samples of Coturnixcoturnix, 10 samples of Meleagrisgallopava; the mammals included 20 samples for these species: Canis lupus, Equusferuscaballus, Oryctolaguscuniculus, 24 samples of Feliscatusand 8 samples of Caviaporcellus. All fecal samples were placed in clean test tubes with the sample numbering, date of the collect was recorded and then it stored in the refrigerator at 4°C after added normal saline until examination.

Examination of stool by using acid fast stain: All stool samples were prepared for microscopic examination, firstly purification by filtering through four layers of medical gauze and put the filtrated stool in a clean test tubes, then it put in centrifuge (2500 rpm) for 10 minutes, finally stool samples were make a smear for staining according to [20]. The positive stool samples which contain oocysts of Isospora belli were stored at -20ºC in freezer to used it for DNA extraction.

Extraction and Amplification of DNA: Positive stool samples were processed to extraction of DNA according to [21] by using 18S rRNA gene with forward primer (5'-CCAGCAGCCGCGGTAATTCC-3') and reverse primer (5'-CGAGCCCCTAACTTTCGTTC-3'), after DNA amplification by PCR, the products were put on agarose gel to prepare for electrophoresis and then DNA products are photographed.

Statistical Analysis: The data were analyzed statistically by using chi square at level of significance of $P \leq 0.05$ with SPSS program.

Results and Discussion

The results of current study showed that birds and mammals under study were infected with *Isospora belli*, 127 specimens was positive from 287 specimens through used acid fast stain technique, with a total percentage 44.25%. The results revealed a significant difference between the highest and lowest infection percentage which were 73.3% followed by 66.7% and 10.0% in *G. gallusdomesticus*, *Anasplatyrhynchos* and *P. leucotis* respectively at p≤ 0.05; while the results showed no infection in guinea pig *C. porcellus*.

With regard to molecular diagnosis of *I. belli* by using PCR technique, when DNA was amplified with 18S rRNA gene, the electrophoresis of amplicons showed band size at 550-630bp for all fecal samples of infected birds under study which were a positive samples with Ziel-Neelsen staining (fig.1), also the amplicons of DNA which belong to infected mammals appeared similar with the bands which isolated from infected birds while there is no bands after electrophoresis for the samples which isolated from guinea pig.(fig. 2).

Fig. 1: Analyzed amplicons of Isospora belli by electrophoresis which isolated from birds, M = Marker 1000bp, the specimens from 1 to 10 represent species of infected birds in the same order of birds that appears in Table (1).

Fig. 2: Analyzed amplicons of Isospora belli by electrophoresis which isolated from mammals, M = Marker 1000bp, the specimens from 1 to 5 represent fecal samples isolated from guinea pig, and the specimens from 6 to 9 represent infected mammals in the same order of mammals that appears in Table (1).

Table 1: the infection percentage with I. belli in birds and mammals under study

Groups of Hosts	Species of Hosts	No. of Examined Samples	No. of Infection	Percentage of Infection (%)
Species of birds	Passer domesticus	30	16	53.3
	Streptopeliadecaocta	15	5	33.3
	Columba livia	25	10	40.0
	Columba domesticus	30	15	50.0
	Anasplatyrhynchos	15	10	66.7
	Anseranserdomesticus	10	4	40.0
	Pycnonotusleucotis	10	1	10.0
	Gallasgallusdomesticus	30	22	73.3
	Coturnixcoturnix	20	8	40.0
	Meleagrisgallopavo	10	6	60.0
Species of mammals	Feliscatus	24	14	58.3

	Equusferuscaballus	20	5	25.0
	Oryctolaguscuniculus	20	5	25.0
	Caviaporcellus	8	0	-
Total No.		287	127	44.25

The results in table (1) indicate to infection with *I. belli* in many species of birds and mammals under study and the outcome of current study is consistent with several studies that have registered the infection with this parasite in various species of wild and pet birds or mammals[1,2,14,17,22], as well as human infection[6,18,19].

The high incidence of parasite in domestic chickens *G. gallusdomesticus* (73.3%) may be due to the conditions of breeding and the interest of cleanliness of the breeding house as well as the presence of other animals like sheep, cows and dogs, likely to be infected with this parasite near the chicken living place, as the infection occurs through eatinga contaminated seeds with infected animal fecal[23-25].

The low rates of infection in the birds and mammals under study can be attributed to the fact that they are very limited in their exposure to the sources of infection, many of birds depending in their feeding on seeds, some worms and insects, so the infection with this parasite could be caused by the sources of drinking water contaminated with oocysts[16,22]. The same reasons could be caused infection in mammals under study like cats, dogs, horses and wild rabbits, they infected through contaminated water or their food with oocysts of this parasite[26-,28]. In addition, oocysts able to maintain their ability to infect for more than a year, with the possibility of long stays in the dirt, water or feces [10,13]

The current infection rates give an important health indicator that must be taken into consideration in the role of these birds in spreading of this parasite to other hosts by putting their oocysts without visible or clearsymptom on infected birds, therefore it contributes in environmental contamination with parasitic infection [9,10].

The Level of Some Immunoglobulin and Antioxidant Enzymes Activities in Patients with Dermatophytosis

Naser Hamzah Jubair AL-Brykiat[1], Zuhair Hameed Abboud AL-Dhwahery[1], Jasem Hanoon Hashim AL-Awadi[1]

[1]Department of Biology, Faculty of Science, Kerbala University, Iraq

Abstract

The current study included collection of 131 clinical samples (91 skin peel samples, 31 hair samples and 9 nail samples), as well as withdrawal of a blood sample from patients with dermatophytes and skin consultants in Hussein Medical City in the holy city of Kerbala in Iraq.

The most fungus isolated was *Microsporumcanis*was 25% of the total samples positive culture then *Trichophyton rubrum* was 15.9%, *T.mentagrophytes* was 13.2%, *Epidermophytonfloccosum*was 11.9%, then *T.verrucosum* was 7.9%, *M.gypsum* was 7.9%, then *T.schoenleinii* was 3.9%, *T.riniacei* was 3.9%, *T.concentricum* was 3.9 %, *T.tonsurans* was 2.6%, *T.interdagtale* was 2.6% and finally *T.violaceum* was 1.3%. The most isolated species of *Trichophyton* species were followed by *Microsporum* species, The highest percentage of Zoophilic dermatophytes was followed by Anthropophilicdermatophytes, the study found that *Tineacorporis* first among clinical cases 41.98%followed by *Tinea capitis* 23.66% and *Tineapedis* 9.16%, *Tineamanum* 7.63%, *Tineaunguium* 6.87%, *Tineafaciei* 5.34% and *Tineacruris* 5.34%, the highest rate of isolation of *T.corporis, T.capitisand T.cruris*of the males while *T.pedis, T.unguiumand T.faciei*highest rate of isolation in females.

The study also showed that age factor affected the incidence of infection it was found that age group ≥ 10 years is the most affected by ringworm and *T.capitis* and T.faciei the most affected in this category, while *T.corporis* is the most affected in age group (20 -11), *T.unguium* is most common injury in age group (21-30), finally *T.pedis* and *T.manum* were most Injury in age group ≤ 40, The results of the present study showed a significant decrease in the values of SOD, CAT and IgE for patients with dermatophytes compared to control group, while there was a significant increase in the value of IgA for patients with skin fungi compared to control group.

Keywords: *Dermatophytes, Catalase, Superoxide dismutase, Immunoglobulin A.*

Introduction

Dermatophytes is one of the most common human pathogens, which are highly correlated with the host and cause chemical and physical changes in the host due to the production of many of the enzymes that are soluble and neutralizing the keratin and host proteins in body areas rich in keratin, the most important enzymes produced (keratinases, lipases, phospholipases, elastases, collagenases and proteases), Dermatophytes differ in their Ability to produce these enzymes, which are main factor of virility and therefore the preferred host, whether human or animal or the environment, which combined together about 40 species and is characterized by keratinophilic and keratinolytic, Not life-threatening but long-term, frequent and difficult to treat[123].

First stages of tinea begin with adhesion of fungus on the skin where it germinates and overcomes the skin barrier, It then produces and releases Keratinases and other important enzymes in breaking surface layer of skin[4].

When dermatophytes colonize skin, they stimulate keratinocytes to produce different types of cytokines that mediate inflammatory response and accumulation of

leukocytes, particularly neutrophils in diseased tissues[5]. two cells of Th1 and Th17 help cells play an important role in controlling skin infection by stimulating cellular immunity, Th17 increases the infiltration of Neutrophils into injury site and also promotes activation of epithelial cells to produce molecules such as Chemotactic and antimicrobial peptides[67].

Host can use different types of mechanisms to eliminate fungal infections, Neutrophil and Macrophages tend to be attracted to skin lesions by Th1-based inflammation[8]. Free radicals are produced by Phagocytosis process against microbes by white blood cells, especially Neutrophils and Monocytes, leading to significant changes in oxidative metabolism and increase in free radicals that cause oxidative stress in cells due to an imbalance between oxidizing agents and antioxidants[9].

Materials and Method

Collection of Specimens: Clinical samples were collected for different ages and for both sexes of patients with clinically diagnosed Tinea disease from specialist skin care specialists at Al Husain Teaching Hospital in Kerbela, included, 78 samples of males and 53 females and age groups ranged from one year to 63 years, Small scabs were taken from the edge of ulcers using a sterile blind blade, Hair samples were obtained using sterile flat forceps and pieces of infected nails were taken with debris under nails after sterilization by sterile scalpel, The samples were transferred to laboratory.

Direct Microscopic Examination: Put some of samples on a glass slide and add a drop of 15% potassium hydroxide solution, then cover slide cover and leave for 5 minutes until keratin melts and then microscopically examined under 10x and 40x magnification to see fungal compositions[10]

Culturing of Specimens: Dseased specimens was placed on petri dishes containing Sabouraud's Dextrose Agar with cycloheximideand chloramphenicol and incubate at a temperature of 27 C° for 4 to 2 weeks.

Blood Samples: Of the same patients with dermatophytes and some healthy patients, 5ml of venous blood was withdrawn with sterile syringes was placed in Gel Tube And left at room temperature for a quarter of an hour and then centrifuged for four minutes and a force rotation of 4000rpm and then separated serum in Eppendorftubes sterilized and kept under high freezing.

Examination and identification of dermatophytes isolates: After 3 days incubation at a temperature of 27 ± 2ºC, petri dishes were examined and monitored daily for 4-2 weeks. The developing fungi were then transferred using a sterilized needle to dishes containing SDA, PDA for purifying them and studying isolated fungal traits for accurate classification. Part of fungal colony was taken using a sterile needle and placed in a drop of LPCB dye placed on a glass slide After placing the slide cover, it was tested with a light microscope and with a 40 x magnification force to observe various fungal structures such as hypha and non-sexual spores Macroconidia, Microconidia and Chlamydospores.

All isolated fungi were identified during the study period depending on the characteristics of the colonies such as nature of fungal colonies, shape, color, size, texture, contrasting pigments produced by back of dish and changes that occur with age, as well as the microscopic characteristics which include nature of fungal structures, spores Large and small in terms of shape, size, number, thickness of walls, dividers, number of existing cells and based on the following taxonomic sources[11121314].

Immunological and Biochemical tests:

Detection of IgE: IgE ELISA Kit was used to measure the amount of IgE in the human serum. The method used to detect IgE is sandwich assay muthed, which is based on streptavidin-biotin principle. Antibodies in the human serum are linked to the antigen found inside drill through interaction of streptavidin-biotin proteins that are not connected by washing with washing solution are then added Horseradish peroxidase (HRP) to anti-IgE-antibody reagent. sandwich complex is then washed to remove proteins and unconnected enzymes and then add base material that gives chromatic density according to IgE concentration in serum sample.

Detection of IgA: IgA ELISA Kit was used to measure the amount of IgA in the human serum, where the tissue consists of a thin plate initially coated with IgA antibodies, then serum samples and standard solutions, biotin-conjugated antibody specific to IgA and Avidin conjugated to HRP After incubation, TMB solution is added, resulting in a change in color in the holes containing IgA, reaction between the enzyme and the base material is then suspended by adding a sulphuric acid solution the optical density of ELISA reader is measured below 450nm.

Superoxide Dismutase (SOD) Activity:

Table 1: Shows the procedure that used for measurement of SOD activity[15,16].

Reagents	Test (µl)	Control(µl)
Serum	50	-
Tris buffer	1000	1000
Distil water	-	50
Pyrogallol	1000	1000

Absorption was read at the wavelength of 420 nm against Tris-EDTA buffer at zero time and after 1 minute of the addition of pyrogallol.

Catalase (CAT):

Table 2: Shows the procedure that used for measurement of catalase activity[17].

Reagents	Test	Standard	Blank
Sample	100µl		
Distil water		100µl	2100µl
Hydrogen peroxide	2000µl	2000µl	
Mix with vortex and incubate at 37C° for 2 min, after that, add:			
Vanadium reagent	2000µl	2000µl	2000µl
After that, the tubes were kept at 25C° for 10min. changes in absorbance were recorded at 452nm against the reagent blank.			

Statistical Analysis: Data subjected to analysis using IBM SPSS Statistics version 22.0 Comparisons among proportions performed using Independent-Samples-T-test, P≤0.05 was considered as significant.

Results

Most common type of fungus isolated was *M.canis* It was found that 19 samples of samples obtained were due to this fungus and rate 25% of total samplepositive culture, then *T. rubrum* with 12 samples and rate 15.9%, followed by *T.mentagrophytes* with 10 samples and rate 13.2%, then *Epidermophytonfloccosum* with 9 samples and 11.9%, then *T.verrucosum* with 6 samples and rate 7.9% and *M.gypsum* with 6 samples and 7.9%, *T. schoenleinii* with 3 samples and rate 3.9%, *T.erinacei* with 3 samples and rate 3.9%, *T.concentricum* with 3 samples and rate 3.9% and *T. tonsurans*with 2 samples and rate 2.6%, *T.interdagtale* with 2 sample and rate 2.6%, finally was *T.violaceum* only one sample and rate 1.3% (Table 3, Table 4).

The results of present study showed a significant decrease in values of SOD and CAT for patients with dermatophytes compared with control group. The current study showed a significant decrease in IgE for patients with dermatophytes compared with control group. Whilethe current study showed insignificant increase in IgA for patients with dermatophytes compared with control group (Table 5).

Table 3: Frequency of types of isolated dermatophytes relative to clinical patterns that cause them

Type of Dermatophytes	Type of Tinea							Total
	T. Pedis	T. Manum	T. Cruris	T. Unguium	T. Faciei	T. Corporis	T. Capitis	
	Percentage of frequency							
M.canis			2		1	8	8	19
T.rubrum	1	2		4	1	2	2	12

Type of Dermatophytes	Type of Tinea							Total
	T. Pedis	T. Manum	T. Cruris	T. Unguium	T. Faciei	T. Corporis	T. Capitis	
	Percentage of frequency							
T.mentagrophytes		1	1			6	2	10
E.floccosum	3		2	1		3		9
T.verrucosum	1					4	1	6
M.gypsum					1	3	2	6
T.schoenleinii							3	3
T.eriniacei		1			1	1		3
T.concentricum			1		1	1		3
T.tonsurans						1	1	2
T.interdagtale						2		2
T.violaceum							1	1
Total	**5**	**4**	**6**	**5**	**5**	**31**	**20**	**76**

Table 4: Distribution of clinical patterns of tinea relative to age and sex

Type of tinea	Sex	Age groups/years					Total	%
		≤ 41	40-31	30-21	20-11	≤10		
T.corporis	Male	2	5	6	17	7	37	28.43
	Female	1	3	2	5	7	18	13.71
T.capitis	Male	1	1	2	3	14	21	16.01
	Female				1	9	10	7.61
T.pedis	Male	1			1	1	3	2.28
	Female	4	2	2		1	9	6.86
T.manum	Male	3		1	1		5	3.81
	Female	3	2				5	3.81
T.unguium	Male	1	1	1			3	2.28
	Female	1		3	1	1	6	4.57
T.faciei	Male			1	1	1	3	2.28
	Female			1	1	2	4	3.02
T.cruris	Male			2		3	5	3.81
	Female	1		1			2	1.52
Total	131	18	14	22	31	46		100

Table 5: Concentration of SOD, CAT, IgA and IgE in patients with dermatophytes and healthy individuals.

Test	Group	Concentration Rate	Standard Deviation	P. Value
SOD(U/ml)	Healthy	1.72	0.210	0.016*
	Patient	1.30	0.525	
CAT(U/ml)	Healthy	0.34	0.061	0.001*
	Patient	0.19	0.130	
IgE(IU/ml)	Healthy	320.04	153.493	0.004*
	Patient	142.23	174.390	
IgA(ng/Ml)	Healthy	17.74	3.06	0. 11*
	Patient	19.39	2.18	

* Significant difference ≤ 0.05

Discussion

Results of present study show that most isolated fungus species belong to Trichophyton species, followed by genus Microsporum species, Zoophilic is also considered leading cause of ringworm, as it causes many types of ringworm such as ringworm, body, face, foot, mouth and hand. Animals play an important role in the spread and transfer of fungus to humans, as a result of direct and indirect contact with infected domestic animals such as cats, dogs and cattle and it is difficult to control and distinguish them as they do not show any symptoms of fungal infection[10].

Anthropophilic infection is caused by moving from one person to another through direct contact or use of contaminated instruments and clothing for the infected person, while the proportion of infection preferred Geophilic low may be due to the nature of the community from which the sample and most of the city, Fungi transmitted from soil to man or animal, causing skin injury when there are appropriate conditions, this finding is consistent with several studies including[1819].

The results of present study showed a significant decrease in values of SOD and CAT for patients with dermatophytes compared with control group. This decrease may be attributed to consumption of antioxidants enzymatic result of the increase of free radicals resulting from phagocytosis by white blood cells (WBC), especially Neutrophils and Monocytes against dermatophytes[2021]causing oxidative stress due to inflammation and destruction of the affected skin, or may return to the decline in the level of some elements such as Copper (Cu) and Zinc(Zn) which enters into the synthesis of these enzymes or acts as co-factorenzyme[2223].

WBC, especially Neutrophils and Monocytes as an immune response against infection, stimulate the production of Reactive Oxygen Species (ROS), leading to a change in oxidative metabolism, Free radicals increase the oxidative stress of cells, resulting in imbalances and imbalances between oxidative and antioxidant factors[9], which is considered an enzymatic (CAT, SOD) of the most important antioxidant enzymes, where the production of the enzyme CAT to resist the toxicity of hydrogen peroxide (H2O2) and the enzyme SOD to resist the toxicity of superoxide (O2) Phagocytic cells against microbes[24].

The current study showed a significant decrease in IgE for patients with dermatophytes compared with control group. The cause of IgE reduction may be due to T-Helper 1 activity in fungal skin infections[2526], leading to the production of interleukins such as INF-$^{\delta}$, IL-2, which inhibit the effectiveness of T-Helper2 and thus its inability to produce some interleukins such as ILL4 and IL5 important in the production of IgE,.

While the current study showed insignificant increase in IgA for patients with dermatophytes compared with control group that IgA inhibits the adhesion and penetration of the mucous membranes in body, which is one reason why the internal organs of skin are not infected with the fungal infections[2728].

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Abstract

HCMV has been detected in various types of tumors. Besides its well-describedoncomodulation, recently an oncogenic properties of HMCV per se as well asits direct transforming role in infected cells have been described.HCMV in serous ovarian adenocarcinoma and its relation to BRCA1and BRCA2 was scarcely studied.

The study was designed to examine cellular dysregulation mediated by the concordant protein expressions of BRCA1 and BRCA2 tumor suppressor genes with HCMV in tissues from ovarian cancers.

Eighty ovarian tissues were examined for HCMV-DNA and BRCA1 & BRCA2 genes expression. Those samples belonged to (40) patients diagnosed with ovarian cancer and (40) from apparently normal ovarian tissues. The detection of HCMV-DNA was done by chromogenic in situ hybridization (CISH) whereas the translated proteins of the expressed BRCA1 & BRCA2 genes by immunohistochemistry (IHC).

Positive signals of HCMV-DNA -CISH reactions in malignant serous epithelial ovarian tumors, was detected in 45% (18 out of 40)tissues and followed by the apparently healthy ovarian control tissues (12.5%,5 out of 40 tissues). The difference of the HCMV in ovarian cancers and control was highly significant. The translated proteins of the expressed BRCA1 & BRCA2 genes was detected by IHC in 60% (24 out of 40 tissues) of malignant serous epithelial ovarian tumors while no signal was reported in the control tissues. The difference between the percentages of BRCA1 as well as BRCA2proteins detection in ovarian cancer & control group was statistically significant (<0.05).

The significant detection of either HCMV o r*BRCA1 & BRCA2* genes expression in the studied ovarian cancer tissues could support a role for that virus along with these genes in ovarian carcinogenesis.

Keywords: *Serous Epithelial Ovarian Carcinoma, HCMV, CISH, IHC, BRCA1 & BRCA2.*

Introduction

Ovarian tumors are a heterogeneous tumors arising from different cell types while surface epithelial ovarian carcinoma (EOC) are the most frequent types representing 90% of all malignant neoplasms. Ovarian cancer is on the riseand is occurring in about one out of 57 women [(1)]. Iraqi cancer registry in 2005, has ranked ovarian cancers as the fifth of female cancers. Like other cancers, the ovarian carcinoma follows a multistep pathway involving activation of certain oncogenes and inactivation of tumor suppressor genes, as well as involvement of other genes and external mutagens[(2;3)]. The involvement of HCMV infection in epithelial ovarian cancer is an interesting issue in this regards.

BRCA1 and *BRCA2* tumor suppressor genes act as sensors of DNA damage and participate in DNA repairing processes. *BRCA* genes are expressed in the cells of breast and other tissues, where they help in repairing a damaged DNA, or destroying cells when DNA cannot be repaired. Therefore, if *BRCA* itself is damaged, the damaged DNA is not repaired properly and thus increasing risks of cancers [4].

Human cytomegalovirus is also associated on serological and molecular basis with the development and/or the etiology of several human cancers[5] via onco-modulationthat catalyzean oncogenic processes for a more malignant phenotype. HCMV infection might lead to protection of these tumor cells from apoptosis and modulating angiogenesis [6].

Many molecular method for identification of HCMV - nucleic acids are available, where chromogenic in situ hybridization (CISH) can be used with frozen cells and tissues, cytological preparations and fixed tissues, using radioactive- labeled probes or probes with non-radioactive labels such as fluorescent moieties- biotin-digoxigenin- or enzyme- conjugated probes [7-9].

BRCA1 and BRCA2 genes-germ line mutations were reported to lead forhigh life-time risk of ovarian cancers, which are the most significant as well as characterized genetic risk factors so far identified in the disease. BRCA1 and BRCA2 are responsible for 50% of all families containing two or more ovarian cancer cases[10].

Materials and Method

Eighty formalin-fixed, paraffin- embedded ovarian tissues were enrolled in this study; (40) biopsies from ovariancarcinoma as well as (40) apparently normal ovarian control tissue group.

The detection of *HCMV* by *CISH* kit (Zyto Vision GmbH. Fischkai, Bremerhaven. Germany). While, Immunohistochemistry/Detection system (Abcam. England) was used to demonstrate the *BRCA1 & BRCA2* expression (protein) in cells using a specific monoclonal antibodies.

Chi –square test was used to detect the significance between variables of our study. All the statistical analysis was done by SPSS program (Version– 21) & p value ($p>0.01$).

Results

Age Distribution Among Study Groups: The patient's ages ranged from 27-74 years with a mean of 41.215 years. The mean age of patients with malignant ovarian tumors (44.66 years) was higher than the mean age of the apparently healthy control(AHC)(37.77years). There was highly significant difference at ($p<0.01$) between different groups in age distribution.

Histopathlogical Grades of Malignant Ovarian Tumors: The results reveal non-significant differences at ($P>0.05$) between poorly differentiated grade and well differentiated grade, also non-significant difference was noticed between poorly differentiated and moderately differentiated ovarian carcinomas (Table 1).

Table 1: Grading of ovarian cancers group.

Ovarian Cancers		Total (N=40)	%	P-value
Grades	I	12	30	χ^2 test P=0.654 Non sign. (P>0.05)
	II	15	37.5	
	III	13	32.5	

Results of HCMV in Female Patients with Ovarian Tumors: Figure 1 shows In Situ Hybridization (CISH) for HCMV Deduction Benign Ovarian Tumors Using Digoxigenin-Labeled *HCMV* Probe, where 45%showed positive signals, **followed by** the apparently healthy ovarian control tissues **was 12.5%.** Statistically, significant difference ($p<0.05$) was found on comparing the percentages of HCMV DNA among the study groups.

Negative HCMV–CISH reaction (40X). B. Positive HCMV-CISH reaction with low score and moderate signal intensity (40X).

The results of BRCA-1- IHC gene expression in Serous Epithelial Ovarian Tumors: BRCA-1 gene expressionwas detected by IHC test in 60% of malignant serous epithelial ovarian tumors. While, no signal was reported in the tissues of control group (Table 2).Statistical analysis of the BRCA-1 gene expression–IHC tests show highly significant difference (p>0.05).

Table 2: The results of BRCA-1- IHC gene expression in ovarian tumors.

BRCA-1-IHC Gene Expression		Studied Groups		Pearson Chi-Square (P-value)
		Healthy Control	Serous Epithelial Ovarian Cancer	
Positive	N	0	24	P=0.003 highly sign. (P>0.05)
	%	0.00%	60%	
Negative	N	40	16	
	%	100%	40%	
Total	**N**	**40**	**40**	
	%	**100.0%**	**100.0%**	

The results of BRCA-2- IHC gene expression in Ovarian Tumors: BRCA-2 gene expressionwas detected by IHC test in 50%of malignant serous epithelial ovarian tumors.But no signal was reported in the control tissues group. Statistical analysis of the BRCA-2 gene expression –IHC tests show highly-significant difference (p>0.01) Table (3).

Table 3: The results of BRCA-2- IHC gene expression in Ovarian Tumor.

BRCA-2-IHC Expression		Studied Groups		Pearson Chi-Square (P-value)
		Healthy Control	Serous Epithelial Ovarian Cancer	
Positive	N	0	20	P=0.003 Highly sign. (P<0.01)
	%	00.0%	50%	
Negative	N	40	20

A.surface epithelial ovarian tumor with negative BRCA2-IHC reactions (40X)B.Positive BRCA2-IHC signals of surface epithelial ovarian cancer (40X).

Correlations among of studied markers (wide spectrum HCMV, BRCA1, BRCA2) in patients with Serous Epithelial Ovarian Cancer.

HCMV: There is a strong positive relationship (with highly significant correlation) between HCMVand grade of ovarian cancers. {r = 0.83, P = 0.612,.(p <0.01)}. However, there are no significant correlations among HCMV and other markers. Also,a strong positive relationship (with highly significant correlation) between BRCA1 and BRCA2 marker in ovarian cancers {r = 0. 573, P = 000, (p <0.01). Finally a strong positive relationship (with highly significant correlation) between BRCA2 and age in malignant ovarian tumors {r = 0. 483, P = 0.02, (p <0.01)} (Table 4).

Table 4: Spearman's rho statistical testing to evaluate studied molecular markers in relation with HCMV infections in Serous Epithelial Ovarian Cancer

Spearman's rho		Age Groups/Year	Grade	HCMV	BRCA1	BRCA2
Grade	r.	-.135				
	P-value	.414				
HTLV-1	r.	.083	-.632**			
	P-value	.612	.000			
BRCA1	r.	.065	-.055	.000		
	P-value	.689	.740	1.000		
BRCA2	r.	.483**	-.067	-.105	.573**	
	P-value	.002	.684	.517	.000	

*Correlation is significant (P<0.05). **Correlation is highly significant (P<0.01).

Discussion

Patients with ovarian cancers have poor survival despite advances in molecular biology, diagnostic imaging, multidisciplinary surgical and oncological treatments[11]. In general, the aging increases incidence of the malignant changes in ovarian epithelial tissues and as such their incidence increased with age[12].

In this respect, ovaries of older women showed

higher morphological changes than the ovaries of younger women [13]. Ovulation and subsequent repairing lead to age-dependent changes (so-called ovarian ageing), this might represent a critical pre-neoplastic lesions [14].

Gong *et al*.,[15]reported that ovarian carcinogenesis involved some mechanical sequelae of ovulation, such as trauma or mitotic stimuli to the ovarian epithelium. Similar to pregnancy, women with later menarche might decrease the risk of ovarian cancers by decreasing lifetime number of ovulations.Cellular immune responses in the resolution of viral infections and that deficiencies in cell-mediated immunity increase the likelihood of disease persistence or progression in those older women (waning immunity), as well as intransplant recipients, HIV patients and patients receiving immunosuppressive drugs [16].

Elucidating the potential role of HCMV in epithelial ovarian cancers is of great interest given the availability of antiviral therapies that may be active in this disease. Chromogenic in situ hybridization proved powerful methodfor revealing specific genetic markers as well asgene expression in a morphologically preservedtissue context [17].

Joseph *et al*., [11] found that 40% -80%of ovarian cancer tissueshave CISH expressions of HCMV (IE- and pp65-genes expressions).These observations indicatethe occurrence of reactivation of latent HCMV within the tumor as both viral proteins could be detected in tumor tissue sections,although unlikely (and cannot being excluded) the virus has infected the tumor on later occasions. This supports a previous report by Shanmughapriya*et al*.,[18] who HCMV-glycoprotein DNA by polymerase chain reaction in 50% of ovarian cancer tissues.Previous studies implied a potential role for inflammatory factors in the processof ovarian malignancy [19] while others revealed that Inflammation is a key factor in the reactivation of latent HCMV. The increased production of inflammatory factors)such as IL-1β, IL-6, IL-8, tumor necrosis factor-α, transforming growth factor-β, viral IL-10, prostaglandins and leukotrienes) in active HCMV infection may aggravate the inflammatory microenvironment [20].

HCMV-pp65 contributes also inimmunosuppression by downregulation of the interferon response. The activity of HCMV in a tumor may promote disease progression and prevent desired effects of chemotherapy in some cancer patients. This viral ability delay or prevent apoptosis so as to prevent the therapeutic action of chemotherapy in HCMV-infected tumorcells [21]. Despite a limited number of specimens in this study, the currentfindings may indicate a role for HCMV in ovarian cancers. Further studies should focus on validating these findings in a larger cohort of patients.

Cancer risk of *BRCA1*and *BRCA2*mutations is inherited in a dominant fashion.BRCA1/2 absence functions are associated with risk for developing epithelial ovarian cancers: 40% - 50% in patients with BRCA1-mutations and 20% - 25% in patients with BRCA2-mutations [26].

Identification of *BRCA* mutations in this substantial proportion of the studied Iraqi patients indicates that these genes still play an important roles in the ovarian carcinogenesisamong the general population. The current results are supported by the meta-analysis results of families by Antoniouet al., [26] & Pal et al., [27] where they found the life-time cumulative risks for ovarian cancer was estimated to be 40–53% in those carriers with BRCA1mutation and 20– 30% in those carriers with BRCA2 mutation.

Conclusion

The significant detection of either HCMV or *BRCA1 & BRCA2* genes expression in the studied ovarian cancer tissues could support a role for that virus along with these genes in ovarian carcinogenesis.
