**ABSTRACT**

*New residence of local fisherman will be built in Puger Kulon Village in the District of Puger, Jember. This area is quite densely populated with a density of 376 inhabitants/ha. The physical condition of this area is sandy soil, the spaces between houses are about 1-2 m, it is located near the river, approximately 200-300 m from the beach, and 1000 houses are being planned to be built on an area of 34.71 ha. On site waste water system (septic tank) is not suitable to be used in this area, because infiltration from the septic tank can easily penetrate into the soil and pollute ground water and rivers in this area. Three alternatives of wastewater pipe networks were scenario 1, scenario 2, scenario 3 then most effective and efficient will be selected pipeline scenario. Scenario number 1 was selected as the most effective and efficient shallow sewer pipeline system because scenario 1 has an average velocity of 0.6229 m/s, the smallest total energy loss of 0.279488, efficiency in pipe length of 47.3 % and ease of maintenance when clogging occurs. The diameter of pipes in the pipeline is 75 mm. The smallest dimension for the pipelines connected to communal tanks is 100 mm, whereas the biggest dimension is 250 mm. The shallow sewer system requires water as much as 0.001988 m<sup>3</sup>/s for flushing maintenance.*

**Key words:** residence of fisherman, shallow sewer, Puger Kulon.

## SUMMARY

**Domestic Waste Disposal System Design of Fisherman Residence in Puger with Modular System – Shallow Sewer;** Feri Ejin, 061910301111; 2010, 66 pages; Department of Civil Engineering Faculty of Engineering, University of Jember.

Domestic waste water is wastewater from residential activities such as housing, schools, hotels, shops, and offices resulting from human activities such as human feces (*black water*), bath, kitchen, and laundry waste which can be processed together or separately. New residence of local fisherman will be built in Puger Kulon Village in the District of Puger, Jember. This area is quite densely populated with a density of 376 inhabitants/ha. The physical condition of this area is sandy soil, the spaces between houses are about 1-2 m, it is located near the river, approximately 200-300 m from the beach, and 1000 houses is being planned to be build on an area of 34.71 ha. On site waste water system (septic tank) is not suitable to be used in this area, because infiltration from the septic tank can easily penetrate into the soil and pollute ground water and rivers in this area. Domestic waste water system with a shallow sewer-modular system can be used as a solution to this problem. The purpose of this study is to determine an effective and efficient modular piping system for the disposal of domestic waste by using the shallow sewer method and to determine the appropriate diameter of pipes used.

This research was conducted to select the most effective and efficient shallow sewer pipeline system (scenario 1, scenario 2, and scenario 3). The parameters used to select the pipelines are the flowrate of domestic waste, the slope of the channel, the velocity limits in the pipeline channel (0.5 m/s – 1.2 m/s), the smallest total energy loss, the dimension of pipes and efficiency of used pipe length, and the maintenance of the piping system.

Scenario number 1 was selected as the most effective and efficient shallow sewer pipeline system among the other scenarios as a result of this research. This was

concluded because scenario 1 has an average velocity of 0.6229 m/s, the smallest total energy loss of 0.279488, efficiency in pipe length of 47.3 % and ease of maintenance when clogging occur. The diameter of pipes in the pipeline is 75 mm. The smallest dimension for the pipelines connected to communal tanks is 100 mm, where as the biggest dimension is 250 mm. The shallow sewer system requires water as much as 0.001988 m<sup>3</sup>/second for flushing maintenance.
